It has not been found possible with the existing practice of wood casing and two wires to make any provision against the other sources of danger, which really are the most serious. But by the system of concentric wiring these dangerous properties have been entirely set aside by a mode of construction, and the simplicity and substantial and durable character of electric lighting greatly enhanced. The wires used in this system are constructed one inside of the other, separated by an insulating substance. By this construction the conductors are arranged so near to each other that it is impossible for one of the wires to be deranged without affecting both, and causing that defect which is protected by the fuse. When any such accident does occur, it is contained within the surrounding tube conductor, and it only lasts for an instant.

It is also claimed that concentric wiring is cheaper in first cost than the two-wire system; this we venture to doubt, providing that every particular and detail is constructed in accordance with Mr. Andrews's rules. Our opinion is supported by Mr. Rankin Kennedy, who says that the single wire system is more expensive to erect than the two-wire system, if the work be properly done.

Considerable care has been given to render the rules complete, so as to embrace all points that may arise in practice. From a note at the end, we also infer that they are satisfactory to the fire insurance companies; the note states that installations carried out in accordance with the rules can be insured at the ordinary rates.

Some extra rules for ship lighting are appended, which should be valuable to those who are not much acquainted with electric work on board ship.

## NOTES.

**Telephony in the North.**—It is reported that a deputation from Rothesay has called on Mr. Muirhead, whose name has of late come so much before the public in connection with the £4 per annum telephone company, and he has been asked to estimate for the erection of wires; and the establishment of an exchange in Rothesay, to be fitted up with French instruments. The Postmaster-General is also being asked to grant a license to carry it on, on the usual terms.

**Accident at a Paris Lighting Station.**—Three firemen employed at the electric lighting "installation" at the Palais Royal, which supplies the Comédie Française and the neighbourhood around, were injured seriously at a late hour on Monday night by the explosion of a steam pipe connected with the engine. Many of the lights in the theatre were extinguished temporarily, but there was no interruption in the performance. On Tuesday evening one of the wounded men died.

**A Curious Break in a Converter Primary.**—A correspondent writing from Chicago to the *New York Electrical Engineer*, says:—I would call the attention of your readers to a sample of wire taken from the primary coil of a converter, which shows an apparently unaccountable break. The ends of the break are fused, while the insulation has not been charred except close to the break. There was nothing to show that this was caused by any cross with the secondary coil, or by any escape to ground. It is accepted by some people as being a freak of lightning, and has come to be such a common occurrence as to amount to a very serious trouble. I would like to enquire whether others have noticed this difficulty, and whether there is any good explanation to give except a fault in the copper finally resulting in a break.

**Telephone Communication.**—The introduction of the telephone to Campbelltown for business purposes is to take place this week, when a telephone is to be established between the Post Office and the shipbuilding yard. Several business firms in the town have already made enquiries with a view to the extension of the telephone system, and the establishment of an exchange at the Post Office.

**Official Report on the Kemmler Execution.**—Dr. Carlos F. Macdonald, president of the State Commission in Lunacy, has furnished Governor Hill an official account of the recent death of William Kemmler, at Auburn Penitentiary, by electricity. He says:—"Compared with hanging, in which death is frequently produced by strangulation, with every indication of conscious suffering for an appreciable time on the part of the victim, execution by electricity is infinitely preferable, both as regards the suddenness with which death is effected, and the expedition with which all the immediate preliminary details may be arranged. By the latter method the fatal stroke renders its victim unconscious in an infinitesimal fraction of a second, so small as to be beyond the power of the human mind to estimate, while, at the same time, it disintegrates the nerve tissues and blood to an extent which insures an absoluteness of death in a shorter space of time than is possible by any other known method. In other words, it is the surest, quickest, most efficient, and least painful method that has yet been devised." Dr. Macdonald makes the following recommendations:—1. The statute providing for the execution of criminals by electricity should be amended so as to provide for but one plant, to be located in the central part of the state, in a building especially constructed for the purpose, the apparatus to be in charge of and operated by a competent, accredited electrician. 2. The engine and dynamo should be especially constructed for the purpose, and should be capable of generating an electromotive force of at least 3,000 volts, in order to insure the maximum voltage that would be necessary, and at the same time cause no injustice to any electrical lighting company, such as is likely to be the case so long as commercial dynamos are used in executing criminals. 3. The voltmeter should be located in the execution room, and a competent and responsible official should be detailed to take the readings of the meter before and at the instant the current is applied. The voltage should not be less than 1,500, nor more than 2,000, and should be a matter of official record. The prisoner's resistance should also be taken immediately before bringing him into the execution room.

**Storage Cars.**—There is yet a good time coming for the storage battery tramcar. The *New York Electrical Engineer* of the 15th inst. contained figures which show that as many storage cars are running to-day as there were of the overhead conductor system only two short years ago. In such a city as New Orleans, for example, the storage system is the only substitute for horses, and there, says our contemporary, it will achieve one of its greatest triumphs. The advocates of the secondary battery on this side will doubtless rejoice to think that the day is not far distant when the same progress will be shown in the United Kingdom.

**Increased Business of the American Westinghouse Company.**—The business of the Westinghouse Electric and Manufacturing Company has received an extraordinary boom during the last month. The shops are now running at their full capacity day and night, and the company has still orders ahead to keep it busy the entire winter. This large increase in the work is especially caused by the wonderful success of the street car motor lately brought out. The manufacture of alternating current apparatus has also gained considerably, and the new Westinghouse system of alternating current arc lighting is rapidly becoming a popular method of illumination.

**Electric Light and Potential Differences.**—Sir David Salomons has contributed to the October number of *Lippincott's* a treatise on electric lighting. It is, of course, of a popular nature, but the following extract may be of service to the ever-increasing race of primary battery inventors who will insist that their galvanic couples are pre-eminently suited to the requirements of electric lighting:—"A lamp (incandescent) intended to give a certain light with a given pressure would give less than half its light with a fall of 10 per cent. in pressure. On the other hand, a 4 per cent. increase of pressure above the normal would produce at least double the light intended." Primary batteries, therefore, intended for electric lighting become almost useless when the difference of potential at their terminals is allowed to fall below 10 per cent.

#### The Electric Lighting of Paris and Foreign Material.

—*Le Matin* publishes the following remarks on the specification of charges of the electric lighting of Paris:—"One of the good results which the Municipal Council's specification of charges imposed on the concessionaires of sectors has certainly brought about has been to force foreign companies, which hitherto had imported their machinery and accessories to manufacture in France, which, as will be understood, is a very great advantage for French manufacturers and workmen. The most striking case is that American company, Babcock and Wilcox, the well-known makers of multi-tubular boilers. Though for four or five years this company has nearly wholly constructed its boilers in France, it only entirely carried them out in France when the Popp order was given to it. This company found itself, by the decision of the Municipal Council, before the alternative of refusing the order which had been given it—a large order of about 10,000 horse-power, intended for a large installation for the electric lighting of the city—or of entirely constructing it in France. The Babcock and Wilcox Company did not hesitate. It entered into an arrangement with Le Creusot, which undertook the construction of the Babcock and Wilcox boilers." From this summary of the facts, it will be seen that the Babcock and Wilcox Company found itself in an exceptionally difficult position, on account of the requirements of the Paris Municipal Council in regard to the secret construction of certain parts of its boilers. Nevertheless, the order was such an important one that a *tour de force* was necessary. The company rose to the situation, as may be judged from what precedes.

**Electric Trains with Storage Batteries.**—The practicability of working electric trains by means of storage batteries still remains an open question; but recently some continuous trials have been made on the Lehigh Avenue Street Railroad in Philadelphia, which appear to be of a satisfactory character, though the total time during which the trial has lasted is hardly sufficient to justify very sanguine hopes of the ultimate success of the system. On the track in question four cars have been operated continuously during the last four months with cells of the railroad type described in our leading pages. This road has numerous curves, and grades as heavy as  $5\frac{1}{2}$  per cent. These have taxed the cells to their utmost, the 100 cells on each car frequently being discharged at the rate of 45 electrical horse-power. During the month of August past, these cars alone carried 59,000 passengers, with frequent loads of 100 passengers on a car. The batteries have frequently made runs of 63 miles with a single charge under these conditions, thus giving a good indication of their increased efficiency where the conditions are more favourable as to grades and curves.

**Fire at Boston Caused by Electricity.**—It is said a fire, which broke out on Sunday last at the office of the Western Union Telegraph Company, was caused by an electric light wire crossing another wire. Work was temporarily suspended.

**The Electrical Transmission of Power.**—For the electrical power transmission installation near Grenoble the water is dammed so as to give an effective head of 230 feet, and is conducted by a steel pipe to the turbine. The generating dynamo is coupled directly to the horizontal shaft of the turbine, and is connected to the two cables by an aerial line, by which the power is transmitted to the motor at Montier, a distance of a little more than three miles. The following particulars are from *Le Genie Civil*:—Generator, 300 horse-power, 240 revolutions per minute; motor, 200 horse-power, 300 revolutions per minute; pressure, 2,850 volts; current, 70 ampères; resistance of line, 3,474 ohms; resistance of dynamo fields, 0.950 ohms; resistance of dynamo armature, 0.984 ohms; resistance of motor fields, 0.731 ohms; resistance of motor armatures, 0.690 ohms; total resistance of circuit, 6.829 ohms; electrical efficiency, 83 per cent.; mechanical efficiency, 65 per cent. This plant has been running since November last. Four men are employed—two at the generator and two at the motor—each being in attendance for twelve hours. A telephone line is run on the same poles as the working line. The line has been struck several times by lightning, but both generator and motor were fully protected. The power is used for driving a paper mill, and the cost is found to be much smaller than when steam was used.

**Arc Lamps with Alternating Currents.**—Mr. Steinmetz, of New York, is stated to have succeeded in effecting the feeding of 125 arc lights, Westinghouse pattern, by means of an equal number of small transformers connected in series on a circuit which carried a constant current of 30 ampères. Each lamp works at 50 volts and 10 ampères, so that for each lamp brought into circuit, the tension increases about 17 volts in the primary circuit, on which, however, it never exceeds 2,000 volts. The advantage of this system is the reduction of the potential in the lamp circuit, while a line at high tension is maintained. The lamps are the same as for continuous current, but with divided electromagnets. They are fitted with special flat and broad carbons, 20 cm.  $\times$  5 cm.  $\times$  0.8 cm. to 1.5 cm., having a durability of 40 hours. The Westinghouse-Stanley machine, which supplies the primary current, has a high self-induction owing to the induced coil being wound with a very large number of turns of wire, and consequently the current varies very slightly with external resistance, about 2 per cent. for tensions varying at the terminals from 1,000 to 3,000 volts. In order that the lamps should work under the best conditions, the speed of alternations of the current was reduced to one-half, the rate adopted being 130 complete periods per second.

**Indurated Fibre for Conduits.**—We read in the issue of the New York *Electrical Engineer* for September 17th that the use of indurated fibre pipes for underground telephone work has assumed considerable importance in Philadelphia. It is made by a patented process from long wood fibres, separated, washed free from all saps and gums, moulded while in a pulpy state into the requisite size and shape, and then subjected to great hydraulic pressure. After this it is treated and hardened by a special chemical process, so that it is rendered impervious to moisture or to the action of acids or gas. It is very tough and durable, and will withstand very great crushing strains. The tensile strength is about 1,100 lbs. to the square inch. Its weight is about one-fifth that of iron for equivalent service in pipe form. It will resist over 200° of heat, is insensible to the greatest cold, and is easily handled. For electric lighting purposes, the man-hole chambers are lined with the indurated fibre, the wires are led through to the pipes by means of rubber tubes, and the chamber is packed with phenicite, a plastic compound resisting moisture and high electrical temperatures. The joints and collars in the service pipes are also cemented with phenicite. The pipes are laid in a concrete of cement, sand, and gravel.

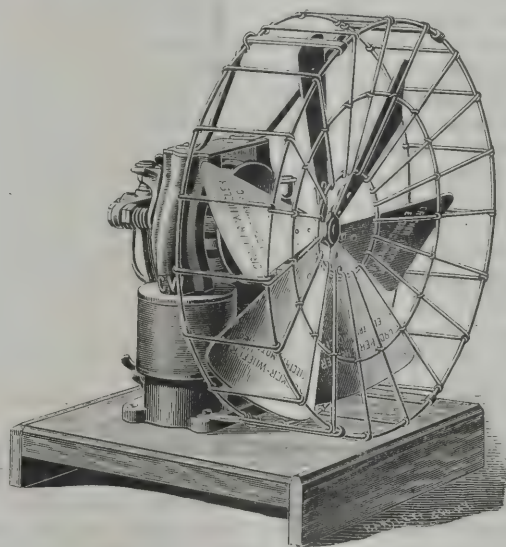

**The Electric Tramcar Accident at Florence.**—The following account of this unfortunate occurrence is taken from a letter to the *Standard*, and as it gives a pretty full description of the accident, may be worth reproduction for future reference:—The line (about 5 miles in length) is laid partly on one side, partly in the centre of the high road, winding, by a long loop, up the steep slope of the well-known Fiesole Hill, and is worked on Sprague's (American) system, by means of a somewhat complicated arrangement of overhead wires, which, owing to the numerous curves, and to the line changing from one side to the other, or being in the centre, are held in position by a series of additional wires, fixed to poles on one or both sides of the roadway. The two sharpest, almost semi-circular, curves occur at a distance of about half a mile from the summit level—viz., the Fiesole Terminus, one of these curves being less than two chains in radius, and the other being so sharp that, in order to avoid it, a back-shunt had to be adopted. The accident occurred on the first of these curves. A car containing 36 passengers (six more than the regulation number) left the summit, and the guard having by mistake failed to apply the current to the brake, the vehicle rushed unchecked, and with tremendous velocity, down an incline of 1 in 14 (7 in a 100), left the rails at the tangent of the curve, and rushed with terrific force against a parapet wall, five passengers being killed on the spot, and 20 more or less seriously injured. The immediate and avowed cause of the accident is said to be the negligence and inexperience of the brakesman, who was himself injured and placed under arrest; but, apart from the dangerously sharp curve referred to, it is difficult to see how an efficient and responsible staff, fit to deal with so powerful and sensitive a motor as electricity, can ever be found to work this line, when a brakesman, who on each journey has the lives of 30 passengers in his hands, receives the miserable wages of a little over two francs per day, and has to be on duty from 6 a.m. to 10 p.m. It is needless to say that the service on the line was at once and entirely stopped by the local authorities pending the inquiry into the accident, which will, moreover, entail on the company heavy compensation. It is a question whether, on a line of this nature, with steep grades and sharp curves, the rack system, or a combination of electric motive power and the rack, would not answer much better than electric power pure and simple, unless additional and independent brakes are provided to ensure safety."

**Telegraph Cable Construction.**—The *Times* has received the following communication from the Foreign Office:—A despatch has been received from her Majesty's Ambassador at Madrid, enclosing copies of a Royal decree authorising fresh tenders to be invited for the construction of the telegraph cables between the Peninsula and the Spanish possessions on the North Coast of Africa. The new conditions are slightly different from those referred to in the notice sent to the newspapers on the 23rd of August last from the Foreign Office. None of the tenders received in answer to the first application have been accepted. The conditions (in Spanish) may be seen at the commercial department of the Foreign Office, London, between the hours of 11 and 5.

**Electric Light in the City.**—The *City Press*, in a recent issue, raises the following query:—"Is it not time that some information should be given as to what steps are being taken with a view of carrying out the contracts for electric lighting of the City entrusted some months ago to the Brush Company and to the Thomson-Houston Co.? The contracts have, I believe, been signed, and there was a limit of time within which the works were to be completed, but so far as I know not the smallest commencement has been made. Indeed, rumour has it that in both instances subsidiary companies are about to be formed to undertake the business. At any rate we are entitled to know something of the matter."

**Englishmen at Mr. Edison's.**—A few days ago over 400 persons, comprising delegates to the meeting of the Mining Engineers and British Iron and Steel Institute, visited the Edison laboratory at Orange, N.J., where they obtained a peep at the famous workshops. Sir John Kitson and many well-known on this side of the water had an opportunity of chatting with Edison, who, an American paper says, derived great pleasure from the visit.

**The Crocker Wheeler Motor.**—These motors (of which we give an illustration) are essentially constructed for use with small currents on central station circuits. They are made from  $\frac{1}{8}$ th to 3 H.P., and can be put in circuit with either incandescent or arc lights. The want of such a motor made in a perfect style has been long felt in England, the motors that have already been supplied not giving satisfaction, mainly owing to want of care in the selection of material and the construction of details, and the success which the Crocker Wheeler motors have

achieved in the United States, there being over 2,000 installed in one year, is due to the perfect construction of the apparatus, its durability, and greater efficiency compared with its size. They are mainly used at present for pumps, fans, lifts, small machinery, &c., but when once introduced into England we have no doubt a great many uses will be found for them, and we think it especially in the interest of central stations to recommend the use of motors in order to make them known, and no doubt in time a considerable revenue will accrue from them. The sole agency for this country has been obtained by the General Electric Company, Limited.

**Electric Lighting at Harecastle.**—Messrs. Woodhouse and Rawson, of Kids Grove, have just completed a very successful installation of the electric light at the Harecastle Hotel. The plant consists of a 110-volt dynamo, driven by a 10 H.P. engine, which supplies 90 16-C.P. lamps.

**The Popularity of Electro-technics.**—With reference to our Note under the above heading, we are informed that of the 596 students receiving technical instruction several hundreds are men already in the electrical industry who are engaged in electrical factories during the day, and who are therefore already provided for.

**Electro-deposition.**—Prof. Andrew Jamieson states that our calculations last week on the electro-deposition of copper exactly bear out his own figures at page 345 of the 6th edition of Munro and Jamieson's pocket-book, viz.:—1 lb. of pure copper deposited requires 4 H.P. We might have added that this will be at least 6 to 8 H.P. indicated, taking everything into account. We hope that Mr. Jamieson may be able to endorse our further contribution to this subject.

**The O. S. A.**—On Friday evening last, the Old Students, Association of the City and Guilds of London Institute held their sixth annual dinner at the Holborn Restaurant, with Dr. Sumpner in the chair. Amongst the guests, we noticed the familiar faces of Profs. Perry and Silvanus P. Thompson, Mr. Kapp, Mr. A. P. Trotter, Mr. Biggs, Mr. Saunders, Q.C., Sir Owen Roberts, and others. Several good speeches, appropriate to the occasion, were made during the course of the evening, and these were alternated with songs and instrumental selections. The number of old students present did not adequately represent the strength of the Association; but we trust that through the energetic endeavours of Mr. W. B. Esson, the President-elect, Messrs. Reckenzaun, Albion Snell, and Reginald Jones (secretary), a new impulse will be given to the gatherings, whether for serious business or social enjoyment. Six years is not a very extended period upon which to form a judgment upon the future of the "Old Students," but we believe that, in view of the number of young men now studying for the electrical profession, such a body might develop into one of a highly useful nature in after years, and we hope that now the helm of the Association is in the hands of practical men who can understand and appreciate the wants of their members, the new session will be the turning point in the somewhat chequered career of these budding scientists and engineers. Success or failure in newly-formed societies may generally be attributed to those in office as much as to any special inducements which may be offered to intending members. Good leaders will always command a large following, and we shall now expect that *esprit de corps* amongst the Old Students which has hitherto been somewhat lacking. To the President-elect and his fellow-workers we wish all success, for we feel well assured that nothing will be wanting on their part to deserve it.

**Telegraphic Communication with France.**—A telegram from Paris, dated yesterday, says:—"At a Cabinet Council held this morning it was decided to sanction the laying of a new telegraphic cable between France and Denmark, in order to obviate the frequent interruptions of communication at present occurring between the two countries. The Ministers also decided to establish telegraphic connection between Marseilles and Tunis, and Marseilles and Oran."

**The Whittingham Magazine Fuse.**—To replace an ordinary cut-out fuse when burnt out it is necessary to perform several small operations which entail a certain amount of trouble, and there is, besides, a risk that the clamping of the wire to the frame may not be efficiently done. In the Whittingham cut-out (an American device) the burnt out fuse is replaced by simply turning a knob through a half revolution. The fuse wire is contained in a small non-conducting cylinder carrying on its spindle a spool on which is wound the fuse wire. On turning the cylinder a wedge-shaped flange or its periphery serves to open a spring jaw, and as the thick end of the flange leaves the clip the jaws come together and catch the end of the fuse protruding from the rear of the wedge. Another half turn of the knob causes the sharp end of the flange to enter between the jaws of the other clip and spread them apart as it passes. The end of the fuse being now held by the first clip, is drawn out from the spool as the cylinder is turned. When the revolution of the cylinder is completed both clips are in action and the fuse wire is firmly held. The convenience of this arrangement is undoubted, but the idea of a magazine fuse is not new, as we have the recollection of seeing such a device some six years back, the manipulation in replacing a burnt out wire was accomplished by the simple plan of opening and shutting the lid of the fuse box.

**Whitby Applies for an Order.**—The District Local Board of Whitby (Yorks) will apply to the Board of Trade for a provisional order.

**Interesting to Engineers.**—The Journal of the Franklin Institute for this month contains the first portion of a paper by Chief Engineer Isherwood, U.S.N., on "The Processes of Steam in its Development of Power by means of the Steam Engine." It is a reprint of the lecture delivered by this gentleman before the Sibley College of the Cornell University, Ithaca, N.Y., in December last. We also note a paper in the "Transactions of the American Society of Civil Engineers" for July last, and which has just come to hand, by Prof. Robert H. Thurston, entitled "A Practical Method for Reducing the Internal Wastes of the Steam Engine."

**The Ferranti Mains.**—It is stated that so much of the new cable is down and at work, that the induction effects, which so greatly troubled the Post Office authorities, have been quite eliminated, and everything is now running well; we believe this statement is not yet borne out by facts, and is decidedly premature.

**Strike of Telegraph Operators.**—Some inconvenience was caused lately on the Mackay system in the United States by a strike amongst their operators, but it appears to have soon been terminated by the demands of the operators being granted in full. The demands were for increased wages, and a promise that only competent men would be employed. This latter request arose from the custom of telegraph pupils being employed to work for nothing until they become expert in the use of the instruments, when they generally offer to work at a certain station for \$10 a month less than the ordinary operator is being paid for it.

**Accumulator Explosions.**—The *Daily Telegraph* of Tuesday had the following paragraph in "London Day by Day":—"An extraordinary explosion took place the other day on board Earl Poulett's steam yacht, the *Pathfinder*, while lying in Portsmouth Harbour, but, fortunately, without injuring anyone. The vessel is lighted throughout with the electric light. Formerly the accumulators were stowed in the coal bunkers, but, as the spot was not easy of access, they were this season placed on deck, encased in lead and covered with teak. The dynamo was worked by a small boiler in the engine room, which also heated the water for general supply throughout the vessel. During a violent storm of rain the steward reported a leak in his cabin from the deck, and, on going to examine the cause, Lord Poulett discovered that the water came down the hole through which one covered wire passed from the accumulators and went to the dynamo. As it was rather dark, he struck a wax match, and immediately a terrific explosion took place, the yacht being shaken from stem to stern. On going on deck, Lord Poulett saw that the whole of the accumulators had exploded, blowing the teak cases to pieces, and sending the glass fragments and the splinters into the air. The dynamo was running at the time, and only ten minutes previously his lordship and the engineer had been examining the cells, with the lids of the cases open, to see in what state the acid was. Each cell had a vent-hole on the top for escape of air and for ventilation, so that how the explosion originated remains a mystery. The electricians declare it to be one of the most extraordinary things they have ever known, and can in no way account for it, as it has hitherto been thought that under no circumstances could gas be generated in accumulators. It would be satisfactory, therefore, if scientific men could find some solution to the problem, otherwise launches and yachts, where electricity is employed, will be looked upon as too dangerous for holiday cruising."

**Subway Rentals.**—The electric light companies complain that the rental for ducts in the new subways in New York are prohibitive, that some companies are being illegally favoured, and that there is no way of deciding the matter except by appeal to the law courts.

**The Institution of Civil Engineers.**—Amongst the subjects suggested for papers for the forthcoming session of this Institution are the following:—"The Lighting of Railway Carriages by Oil, Gas, and Electricity Compared;" "Electrical Traction for Roads and Railways;" "The Design and Arrangement of Electric Supply Stations and of Electric Distributing Apparatus for Domestic, Trade and General Service in Towns, particularly as to Economy and Safety;" "The Comparative Advantages of Gas and Electricity for Lighting Purposes;" "The Application of Electricity to Bleaching;" "Electric Mining Machinery for Pumping, Hauling, and Coal-Cutting in Mines and Collieries;" "The Application of Electricity to Smelting and Metallurgical Operations;" "The Electro-Deposition of Copper;" "The Cost of the Production and Distribution of Electrical Energy;" "The Distribution and Application of Electric Power in Towns;" "Electrical Measuring Instruments, such as Ammeters, Voltmeters, Power-Meters, and Supply Meters."

**National Telephone Company, Limited, Glasgow District Electrical Society.**—This society was inaugurated on Thursday evening, the 16th inst., D. Kinross, cashier of the company, presiding. The office bearers and committee of management were appointed for the ensuing session. The first paper of the session was read by Mr. Aitken, district engineer of the company, his subject being "The Exchange." He recommended single core for all non-multiple boards for compactness and speedy operating. His paper was very interesting and instructive, and was well received by a large gathering of the *employés*.

#### NEW COMPANIES REGISTERED.

**Petronite Syndicate, Limited.**—Capital £6,060, in £1 shares. Object: To adopt an unregistered agreement of 1st October, entered into with Wm. Sinclair, of Hull. To acquire and work patents, inventions and secrets relating to the preparation of enamel, varnish, damp coursings, insulators, coating for submarine cables, &c. Signatories (with 1 share each), F. Gordon Pape, Wm. Gillyott, C. Muirhead, \*G. Bohn, \*D. W. Sissons, J. B. Willows, and T. H. Sissons, all of Hull. The signatories denoted by an asterisk, and R. Barton and Thos. Bailey, are the first directors. Qualification, £100 in shares stock. Remuneration, £10 10s. each per annum, and, in addition, 10 per cent. on all moneys received on the sale of all or any of the patents or secrets of the company. Registered office, Cogan House, Bowl Alley Lane, Hull. Registered 16th inst. by J. A. Jackson and Son, Hull.

**Electro-Chemical Syndicate.**—Capital £5,000, in £1 shares. Objects: To acquire and develop patents, and to carry on any business, whether manufacturing or other, in connection with the working of the same; to acquire or to construct engines, machinery, and appliances of all kinds. Signatories (with 1 share each): C. C. Marriott, 57, Lavender Sweep, S.W.; T. Trummell, Monument Buildings; G. W. Crosby, 20, Abchurch Lane; G. Fumey, Dashwood House; A. Bissland, 4, Copthall Buildings; J. H. Waldock, 16, Chadwick Road, Peckham; E. J. Wills, 46, Mortimer Street, W. Registered 16th inst., without special articles of association, by Lovell and Trummell, Monument Buildings, E.C.

**British Insulated Wire Company, Limited.**—Capital £60,000 in £5 shares. Objects: To manufacture and deal in wire, wire ropes and cables of all kinds, and to carry on business as electricians and as manufacturers of and dealers in electrical apparatus. Signatories (with 1 share each): J. B. Atherton, J. Atherton, Huyton, Lancashire; T. P. Hewitt, S. H. Hartley, Prescott; W. E. Brigg, Keighley, York; J. H. Dodd, Liverpool; J. Beckett, Huyton. The signatories are to appoint the first directors, remuneration £200 per annum, and in addition 10 per cent. of the nett profits remaining after

payment of 10 per cent. per annum dividend on the ordinary shares. Registered 20th inst. by T. T. Hall, 22, Chancery Lane; solicitors, J. and H. Gregory, Leslie and Hartley, Liverpool.

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Schanschieff Electric Light and Power Company, Limited.**—At a general meeting of this company, convened by the liquidators, and held at 32, Poultry on the 17th inst., the accounts of the liquidators, showing the manner in which the winding-up of the company has been conducted and its property disposed of, were laid before the meeting, and were approved and adopted. It was further resolved that the accounts, books, and documents of the company may be destroyed after the lapse of three months.

**National Telephone Company, Limited.**—The annual return of this company, made up to the 12th July, was filed on the 17th inst. The nominal capital is £4,000,000, divided into 740,000 ordinary shares of £5 each, 15,000 first preference shares of £10 each, and 15,000 second preference shares of £10 each. The shares taken up are as follows: 438,984 ordinary, upon which the full amount has been called; 15,000 first preference, upon which the full amount has been called; and 15,000 second preference, upon which £8 per share has been called. The calls paid upon ordinary shares amount to £2,194,920, upon first preference £150,000, and upon the second preference to £120,000.

**Andrews and Preece, Limited.**—The statutory return of this company, made up to the 14th August, was filed 10th ult. The nominal capital is £25,000 in £10 shares, 300 of which are deferred shares; 599 shares are taken up, 300 and 226 ordinary being considered fully paid. Upon 73 ordinary shares £5 per share has been called up, the calls paid amounting to £345, and unpaid to £20.

**Thornebury Miners' Safety Lamp Company, Limited.**—The statutory return of this company, made up to the 17th ult., was filed on the day following. The nominal capital is £50,000, in £1 shares. 30,050 shares are taken up, 20,540 of which are considered as fully paid. Upon 7,480 shares 15s. per share has been called, and upon 2,030 the full amount. The calls paid amount to £6,968, and unpaid to £672.

#### CITY NOTES, REPORTS, MEETINGS, &c.

##### Eastern Extension, Australasia and China Telegraph Company, Limited.

The following report and accounts for the half-year ended 30th June, 1890, was submitted to the thirty-fourth ordinary general meeting, 22nd October, 1890, held on Wednesday last, at Winchester House, Sir John Pender in the chair.

"The usual statements of account for the half-year ended 30th June, 1890, are herewith submitted.

"The gross receipts, including Government subsidies, have amounted during that period to £254,856 18s. 10d. against £256,757 3s. 2d. for the corresponding half-year of 1889.

"The working and other expenses, including £24,508 3s. 10d. for cost of repairs to cables and expenses of ships, absorb £76,670 9s. 3d. against £73,773 10s. 2d. for the corresponding period of 1889, leaving a balance of £178,186 9s. 7d. From this is deducted £2,960 19s. 7d. for income tax, and £38,549 14s. 7d. for interest on debentures and contributions to sinking funds, leaving £136,675 15s. 5d. as the net profit for the half-year. Against this £1,642 11s. 11d. has been charged for additions to staff quarters, and £712 16s. 1d. for expenses in connection with the recent Paris International Telegraph Conference, leaving an available balance of £134,320 7s. 5d.

"One quarterly interim dividend of 1½ per cent., amounting to £31,250, has been paid during the half-year, and another of like amount will be distributed on the 15th instant, leaving £71,820 7s. 5d. to be carried forward.

"The duplication of the New Zealand cable, and the partial renewal of the Madras-Penang section referred to in the last report have been successfully carried out during the half-year under

review, and the cost, amounting to £188,433 15s. 6d. and £80,848 1s. 3d. respectively, has been charged to the general reserve fund, which, after being credited with the profit of £21,103 3s. 4d. made on the sale of investments, and the interest received during the half-year, now stands at £472,713 15s. 3d.

"The subsidy granted by the Spanish Government in respect of the Manila cable expired on the 1st May last, when the balance of the 5 per cent. debentures issued to provide the capital for this cable was paid off, and as the interest and sinking fund contributions have now ceased, there will in future be a saving of revenue on this account of about £5,000 per annum.

"The company's £320,000 six per cent. debentures mature for payment at par on the 1st February, 1891, and your directors have decided to pay them off on that date by issuing a similar amount of 4 per cent. mortgage debenture stock. An extraordinary general meeting will be held immediately after the ordinary meeting at which the necessary resolution will be submitted for the shareholders' approval.

"Negotiations have been entered into with the Governments of Australasia for the establishment of reduced rates to Australia and New Zealand, and the matter is now under consideration in the colonies.

"Arrangements have also been made with the Indian Government for improving the International service; in connection with which the company has decided to duplicate the Madras-Penang cable, and a contract has accordingly been entered into with the Telegraph Construction and Maintenance Company for carrying out the work, which is expected to be completed early next year.

"During the half-year the Tonquin-Hongkong section has been partially renewed by the insertion of 67 nautical miles of new cable, and the operation will be continued as opportunities occur until the line is put into good order.

"The company's maintenance ships have been employed on various cable repairs, but no interruptions materially affecting the revenue have occurred during the past six months. Unfortunately, however, since the close of the half-year telegraphic communication with Australia has been totally interrupted, from the 11th to the 20th July, in consequence of the sudden and simultaneous breaking, through volcanic action, of the three Java-Australian cables near Banjoewangie (Java). This was the more disappointing as it was only last year that the cable to Western Australia was laid mainly with a view to averting such a contingency, but as only two interruptions from volcanic causes have been experienced during a period of nearly 20 years, it is hoped that the cables will now have a long immunity from further trouble of this nature."

The CHAIRMAN, after going over the figures in the report, said the increase in working expenses was accounted for by the fact that the repairs had been heavier than the corresponding period of last year. The laying of the duplicate cable between Australia and New Zealand had since the last meeting been successfully completed, also a partial renewal of the Madras-Penang section; the cost of the two operations had been debited to revenue account. He had often had occasion to explain to them that the object of the company was to keep down capital and keep the system in thorough repair; in that way satisfactory dividends were obtained, and a goodly sum placed to the reserve. On account of the Manila subsidy arrangement having expired and the paying off the capital required for this cable, the company would save about £5,000 a year. The 6 per cent. debentures would be shortly changed to 4 per cent. debentures; a resolution to this effect would be brought before them at the close of the present meeting. Passing on to the question of cable renewals, it was a necessity to have duplication, so that the revenue would never be disturbed. Unfortunately they had nine days' interruption on their cables to the Australian colonies, although they had three cables at work; this was caused by an earthquake. Although rare, a similar occurrence to this happened about 20 years ago; this showed the importance of duplicating even with three cables. It was in one sense unfortunate, though in another it was satisfactory to see how soon repairs could be effected. All these things led him to think that there was no company in the world which could compete with them. That was their strength; they were not monopolists, for they had no exclusive concessions, but they had gradually built up their position, and now they were impregnable. Coming now to the subject of the reduced tariff to Australia, the speaker said there had been a great deal of discussion. The present tariff, 9s. 4d., was reduced by them from 10s. 8d. five years ago. They were fully recouped for the temporary loss in about three years. Another agitation had now begun for a further reduction. Conferences were held with the Agents-General in London, men who were eminently qualified to look after the interests of the Colonies, and with them they resolved, in face of the increasing vitality in the merchant life of Australia and a guarantee from the Government, to reduce their charge to 4s. So confident did the board feel of the success of the scheme, that they were taking half the risk. The increased income to the company would more than justify that action, and at the next meeting they would be able to speak of the success of the scheme. Speaking of the Paris Conference, he would remind honourable shareholders that they anticipated things would go rather hard with them; such had not been the case, however, and they came out of the Conference unscathed. In conclusion, the speaker dwelt with satisfaction on the arrangement made with the Indian Government as to cable work in that part of the world.

The report was then formally moved and seconded.

A few questions were satisfactorily disposed of, and the report and accounts were adopted.

At the conclusion of the ordinary business, an extraordinary general meeting was held for the purpose of considering the following resolutions:—

(a.) "That the board of directors be, and are hereby authorised from time to time to create and issue mortgage debenture stock of the company to an amount not exceeding one-third of the share capital of the company for the time being issued and paid up, upon the terms that the aggregate amount of the said stock for the time being in issue, and the interest thereon, shall rank *pari passu* as a first charge on the undertaking and revenue of the company, the stock to be issued at such times, in such amounts, and on such terms and conditions as the board shall from time to time determine, for the purpose of redeeming by exchange or otherwise the outstanding debentures of the company, or any other purpose to which capital of the company may be lawfully applicable."

(b.) "That the board be, and are hereby authorised to make such provision as they think fit for the registration and transfer of mortgage debenture stock, and for the delivery of certificates thereof, and for the payment of the interest thereon, and generally as to the form and incidents of all documents relating to the said stock, but so that no such provision be inconsistent with paragraph (a) of this resolution."

These were carried unanimously, and the meeting dispersed.

### Brazilian Submarine Telegraph Company, Limited.

THE thirty-fourth ordinary general meeting was held at Winchester House, on Wednesday, under the presidency of Viscount Monck, who in his address remarked that the working of the company was satisfactory. They had paid a dividend of 7½ per cent., added £40,000 to the reserve fund, and paid off debenture debts to the amount of £15,300, which was shown in the report published in the REVIEW last week. There were favourable indications, so far, for the next half-year. Notwithstanding a satisfactory evidence of the state of things, they had undoubtedly a rock ahead of them, which was the termination of their concession, and which would run out in two years or a little over. Many things were being done, and he could assure them that the board watched the interests of the company with increasing vigilance as the time arrived for proper action. At the last meeting, observations were made with reference to statements in the original prospectus of the company. This was a subject on which he was very sensitive, as he was then, as now, chairman, and practically responsible for that prospectus. Of the feeling and disposition of the gentleman who made the remark towards the board he had not a word to say, as the utmost good feeling prevailed. He said truly that there were statements made with reference to a probable yield of 14 per cent. Now what they did on that occasion was an endeavour to establish a relation between the general mercantile movement in the kingdom and telegraphic communication. They did this on the experience of others; figures were quoted which were open to all. They said that the trade to and from the Brazils might be expected to yield 15 per cent.; it had nearly reached that point, and if they considered everything that had been done, he (the speaker) thought the management was open to little objection. During the period of their existence, 16 or 17 years, they had never paid dividends less than 5 per cent., while on some occasions they had reached 7½ per cent. The whole of the system had been duplicated out of revenue, and if the whole of the debentures raised for that purpose were now paid off there would still be a sum of £2,000 for reserve. The plant was in excellent order; the lines were working well; the receipts for the half-year showed an increase on the previous half-year. A decrease in the London expenditure was accounted for by the absence of law charges. An item in the account which was very large was the laying of land lines, which was not likely to occur again. In conclusion, the chairman referred to the death of Dr. Taylor, their Brazilian representative, whose place had now been filled.

Retiring directors and auditors being re-elected, the proceedings terminated.

**The Consolidated Telephone Construction and Maintenance Company, Limited.**—This company has declared an interim dividend for the half-year at the rate of £6 per cent. per annum on the preference shares and £5 per cent. per annum on the ordinary shares, both less income tax, payable on November 14th.

**West India and Panama Telegraph Company.**—The board recommend a payment of 6s. per share to June 30th last on the first preference shares, and £3 per share on account of arrears on the second preference shares. The sum of £1,500 is to be placed to reserve, leaving a balance of £322.

### TRAFFIC RECEIPTS.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending October 17th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,842. The Brazilian Submarine Telegraph Company, Limited. The traffic receipts for the week ending October 17th were £4,891.

## THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.

(Continued from page 471.)

Let me show you yet another experiment. This is the same electro-magnet (fig. 24) which has one flat pole and one rounded pole. Here is an armature, also bent, having one flat and one rounded pole. If I put flat to flat, and round to round, and pull at the middle, the flat to flat detaches first; but if we take round to flat, and flat to round, we shall probably find they are about equally good—it is hard to say which holds the stronger.

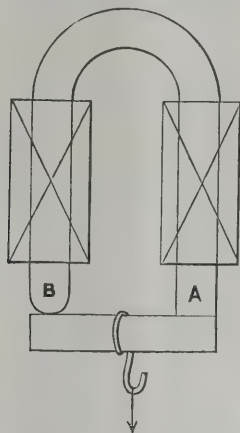

FIG. 25.—EXPERIMENT OF DETACHING ARMATURE.

The law of traction can again be applied to test the so-called distribution of free magnetism on the surface. This is a subject on which I shall have to say a good deal. We must therefore carefully consider what is meant by the phrase. Let fig. 26 be a rough drawing of an ordinary bar magnet. Every one knows that if we dip such a magnet into iron filings the small bits of iron stick on more especially at the ends, but not exclusively, and if you hold it under a piece of paper or cardboard, and sprinkle iron filings on the paper, you obtain curves like those shown on the diagram. They attest the distribution of the magnetic forces in the external space. The magnetism running internally through the body of the iron begins to leak out sideways, and finally all the rest leaks out in a great tuft at the end. These magnetic lines pass round to the other end, and there go in again, and the place where the steel is internally most highly magnetised is this place

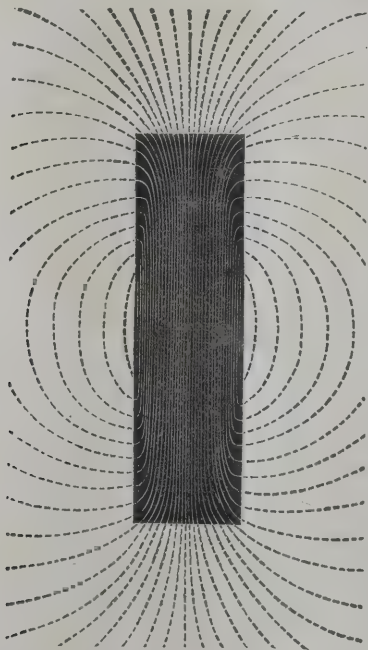

FIG. 26.—LINES OF FORCE RUNNING THROUGH BAR MAGNET.

across the middle, where externally no iron filings at all stick to it. Now we have to think of magnetism from the inside and not the outside. This magnetism extends in lines, coming up to the surface somewhere near the ends of the bar, and the filings stick on wherever the magnetism comes up to the surface. They do not stick on at the middle part of the bar, where the metal is really most completely permeated through and

through by the magnetism; there are a larger number of lines per square centimetre of cross section in the middle region where none come up to the surface, and no filings stick on. Now, we may explore the leakage of magnetic lines at various points of the surface of the magnet by the method of traction. We can thereby arrive at a kind of measure of the amount of magnetism that is leaking, or, if you like to call it so, of the intensity of the "free magnetism" at the surface. I do not like to have to use these ancient terms, because they suggest the ancient notion that magnetism was a fluid or, rather, two fluids, one of which was plastered on at one end of the magnet, and the other at the other, just as you might put red paint or blue paint over the ends. I only use that term because it is already more or less familiar. Here is one of the ways of experimentally exploring the so-called distribution of free magnetism. The method was, I believe, originally due to Plücker; at any rate, it was much used by him. This little piece of apparatus was arranged by my friend and predecessor, Prof. Ayrton, for the purpose of teaching his students at the Finsbury College.\* Here is a bar magnet of steel, marked in centimetres from end to end; over the top of it there is a little steel-yard, consisting of a weight sliding along an arm. At the end of that steel-yard there is suspended a small bullet of iron. If we bring that bullet into contact with the bar magnet anywhere near the end, and equilibrate the pull by sliding the counterpoise along the steel-yard arm, we shall obtain the definite pull required to detach that piece of iron. The pull will be proportional, by Maxwell's rule, to the square of the number of magnetic lines coming up from the bar into it. Shift the magnet on a whole centimetre, and attach the bullet a little further on; now equilibrate it, and we shall find it will require a rather smaller force to detach it. Try it again, at points along from the end to the middle. The greatest force required to detach it will be found at the extreme corner, and a little less a little way on, and so on until we find at the middle the bullet does not stick on at all, simply because there are here no magnetic lines leaking. The method is not perfect, because it obviously depends on the magnetic properties of the little bullet, and whether much or little saturated with magnetism. Moreover, the presence of the bullet perturbs the very thing that is to be measured. Leakage into air is one thing; leakage into air perturbed by the presence of the little bullet of iron, which invites leakage into itself, is another thing. It is an imperfect experiment at the best, but a very instructive one. This method has been used again and again in various cases for exploring the apparent magnetism on the surface. I shall use it hereafter, reserving the right to interpret the result by the light of the law of traction.

I now pass to the consideration of the attraction of a magnet on a piece of iron at a distance. And here I come to a very delicate and complicated question. What is the law of force of a magnet—or electro-magnet—acting at a point some distance away from it? I have a very great controversy to wage against the common way of regarding this. The usual thing that is proper to say is that it all depends on the law of inverse squares. Now, the law of inverse squares is one of those detestable things needing to be abolished, which, although it may be true in abstract mathematics, is absolutely inapplicable with respect to electro-magnets. The only use, in fact, of the law of inverse squares, with respect to electro-magnetism, is to enable you to write an answer when you want to pass an academical examination, set by some fossil examiner, who learned it years ago at the University, and never tried an experiment in his life to see if it was applicable to an electro-magnet. In academical examinations they always expect you to give the law of inverse squares. What is the law of inverse squares? We had better understand what it is before we condemn it. It is a statement to the following effect—that the action of the magnet (or of the pole some people say), at a point at a distance away from it, varies inversely as the square of the distance from the pole. There is a certain action at one inch away. Double the distance; the square of that will be four, and, inversely, the action will be  $\frac{1}{4}$ ; at double the distance the action is  $\frac{1}{4}$ ; at three times the distance the action is  $\frac{1}{9}$ , and so on. You just try it with any electro-magnet; nay, take any magnet you like, and unless you hit upon the particular case, I believe you will find it to be universally untrue. Experiment does not prove it. Coulomb, who was supposed to establish the law of inverse squares by means of the torsion balance, was working with long thin needles of specially hard steel, carefully magnetised so that the only leakage of magnetism from the magnet might be as nearly as possible leakage in radiating tufts at the very ends. He practically had point-poles. When the only surface magnetism is at the end faces, the magnetic lines leak out like rays from a centre, in radial lines. Now the law of inverse squares is never true except for the action of points; it is a "point" law. If you could get an electro-magnet or a magnet, with poles so small in proportion to its length that you can consider the end face of it as the only place through which magnetic lines leak up into the air, and the ends themselves so small as to be relatively mere points; if, also, you can regard those end faces as something so far away from whatever they are going to act upon that the distance between them shall be large compared with their size, and the end itself so small as to be a point, then, and then only, is the law of inverse squares true. It is a law of the action of points. What do we find with electro-magnets? We are dealing with pieces of iron which are not infinitely long with respect to their cross section, and generally

\* Cantor Lecture. Delivered before the Society of Arts, January 27th, 1890.

\* See Ayrton's *Practical Electricity*, fig. 5a, p. 24.

possessing round or square end faces of definite magnitude, which are quite close to the armature; and which are not so infinitely far away that you can consider the polar face a point as compared with its distance away from the object upon which it is to act. Moreover, with real electro-magnets there is always lateral leakage; the magnetic lines do not all emerge from the iron through the end face. Therefore, the law of inverse squares is not applicable to that case. What do we mean by a pole, in the first place? We must settle that before we can even begin to apply any law of inverse squares. When leakage occurs all over a great region, as shown in this diagram, every portion of the region is polar; the word polar simply means that you have a place somewhere on the surface of the magnet where filings will stick on; and if filings will stick on to a considerable way down toward the middle all that region must be considered polar, though more strongly at some parts than at others. There are some cases where you can say that the polar distribution is such that the magnetism leaking through the surface acts as if there were a magnetic centre of gravity a little way down, not actually at the end; but cases where you can say there is such a distribution as to have a magnetic centre of gravity are strictly few. When Gauss had to make up his magnetic measurements of the earth, to describe the earth's magnetism, he found it absolutely impossible to assign any definite centre of gravity to the observed distribution of magnetism over the northern regions of the earth; that, indeed, there was not in this sense any definite magnetic pole to the earth at all. Nor is there to our magnets. There is a polar region, but not a pole; and if there is no centre of gravity of the surface magnetism that you can call a pole from which to measure distance, how about the law of inverse squares? Allow me to show you an apparatus (fig. 27), the only one I ever heard of in which the

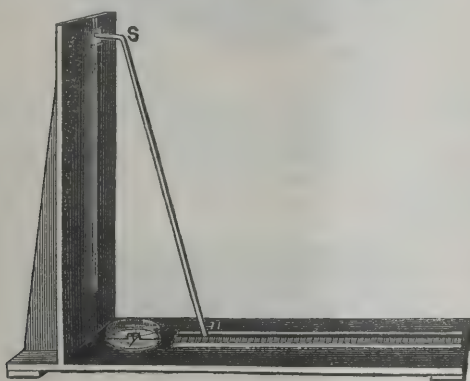

FIG. 27.

APPARATUS TO ILLUSTRATE THE LAW OF INVERSE SQUARES.

law of inverse squares is true. Here is a very long thin magnet of steel, about 3 feet long, very carefully magnetised so as to have no leakage until quite close up to the end. The consequence is that for practical purposes you may treat this as a magnet having point poles, about an inch away from the ends. The south pole is upwards, and the north pole is below, resting in a groove in a base-board which is graduated with a scale, and is set in a direction east and west. I use a long magnet, and keep the south pole well away, so that it shall not perturb the action of the north pole, which, being small, I ask to be allowed to consider as a point. I am going to consider this point as acting on a small compass needle suspended over a card under this glass case constituting a little magneto-meter. If this were properly arranged in a room free from all other magnets, and set so that that needle shall point north, what will be the effect of having the north pole of the long magnet at some distance eastwards? It will repel the north end and attract the south, producing a certain deflection which we can read off; reckoning the force which causes it by calculating the tangent of the angle of the deflection. Now, let us move the north pole (regarded as a point) nearer or farther, and study the effect. Suppose we halve the distance from the pole to the indicating needle, the deflecting force at half the distance is four times as great; the force at double the distance is one quarter as great. Wherefore? Because, firstly, we have taken a case where the distance apart is very great compared with the size of the pole; secondly, the pole is practically concentrated at a point; thirdly, there is only one pole acting; and, fourthly, this magnet is of hard steel, and its magnetism in no way depends on the thing it is acting on, but is constant. I have carefully made such arrangements that the other pole shall be in the axis of rotation, so that its action on the needle shall have no horizontal component. The apparatus is so arranged that whatever the position of that north pole, the south pole, which merely slides perpendicularly up and down on a guide, is vertically over the needle, and therefore does not tend to turn it round in any direction whatever. With this apparatus one can approximately verify the law of inverse squares. But this is not like any electro-magnet ever used for any useful purpose. You do not make electro-magnets long and thin, with point poles a very large distance away from the place where they are to act; no, you use them with large surfaces close up to their armature.

There is yet another case which follows a law that is not a law of inverse squares. Suppose you take a bar magnet, not too long,

and approach it broadside on towards a small compass needle, fig. 28. Of course, you know as soon as you get anywhere near the compass needle it turns round. Did you ever try whether the effect is inversely proportional to the square of the distance reckoned from the middle of the compass needle to the middle of the magnet? Do you think that the deflexions will vary inversely with the squares of the distances? You will find they do not. When you place the bar magnet like that, broadside on to the needle, the deflexions vary as the cube of the distance, not the square.

FIG. 28.

DEFLEXION OF NEEDLE CAUSED BY BAR MAGNET BROADSIDE ON.

Now, in the case of an electro-magnet pulling at its armature at a distance, it is utterly impossible to state the law in that misleading way. The pull of the electro-magnet on its armature is not proportional to the distance, nor to the square of the distance, nor to the cube, nor to the fourth power, nor to the square root, nor to the three-halft root, nor to any other power of the distance whatever, direct or inverse, because you find, as a matter of fact, that as the distance alters, something else alters too. If your poles were always of the same strength, if they did not act on one another, if they were not affected by the distance in between, then some such law might be stated. If we could always say, as we used to say in the old language, "at that pole," or "at that point," there are to be considered so many "units of magnetism," and at that other place so many units, and those are going to act on one another; then you could, if you wished, calculate the force by the law of inverse squares. But that does not correspond to anything in fact, because the poles are not points, and further, the quantity of magnetism on them is not a fixed quantity. As soon

FIG. 29.—CLOSED MAGNETIC CIRCUIT.

as the iron armature is brought near the pole of the electro-magnet, there is mutual interaction; more magnetic lines flow out from the pole than before, because it is easier for magnetic lines to flow through iron than through air. Let us consider a little more narrowly that which happens when a layer of air is introduced into the magnetic circuit of an electro-magnet. Here we have (fig. 29) a closed magnetic circuit, a ring of iron, uncut, such as that on which we experimented last week. The only reluctance in the path of the magnetic lines is that of the iron, and this reluctance we know to be small. Compare fig. 29 with fig. 30, which represents a divided ring with air gaps in between the severed ends. Now air is a less permeable medium for magnetic lines than iron is, or, in other words, it offers a greater magnetic reluctance. The magnetic permeability of iron varies as we know both with its quality and with the degree of magnetic saturation. Reference to Table III. shows that if the iron has been magnetised up so as to carry 16,000 magnetic lines per square centimetre, the permeability at that stage is about 320. Iron at that stage conducts magnetic lines 320 times better than air does; or air offers 320 times as much reluctance to magnetic lines as iron (at that stage) does. So then the reluctance in the gaps to magnetisation is 320 times as great as it would have been if the gaps had been filled up with iron. Therefore, if you have the same magnetising coil with the same

battery at work, the introduction of air-gaps into the magnetic circuit will, as a first effect, have the result of decreasing the number of magnetic lines that flow round the circuit. But this first effect itself produces a second effect. There are fewer magnetic lines going through the iron. Consequently, if there were 16,000 lines per square centimetre before there will now be fewer—say only 12,000 or so. Now refer back to Table III., and you will find that when  $B$  is 12,000 the permeability of the iron is not

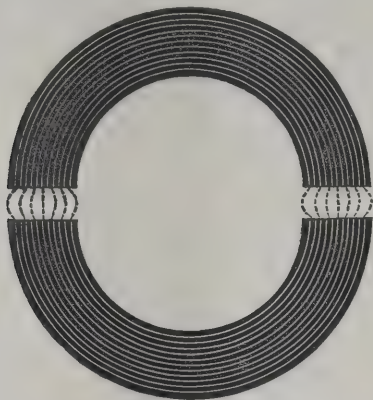

FIG. 30.—DIVIDED MAGNETIC CIRCUIT.

320 but 1,400 or so. That is to say, at this stage, when the magnetisation of the iron has been pushed only so far, the magnetic reluctance of air is 1,400 times greater than that of iron, so that there is a still greater relative throttling of the magnetic circuit by the reluctance so offered by the air-gaps.

Apply that to the case of an actual electro-magnet. Here is a diagram, fig. 31, representing a horseshoe electro-magnet with an armature of equal section in contact with it. The actual electro-magnet for the experiment is here on the table. You can calculate

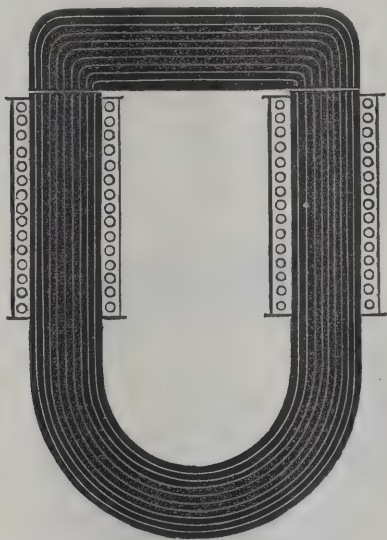

FIG. 31.—ELECTRO-MAGNET WITH ARMATURE IN CONTACT.

out from the section, the length of iron, and the table of permeability, how many ampère turns of excitation will produce any required pull. But now consider that same electro-magnet, as in fig. 32, with a small air gap between the armature and the polar faces. The same circulation of current will not now give you as much magnetism as before, because you have interposed air gaps; and by the very fact of putting in reluctance there the number of magnetic lines is reduced.

Try, if you like, to interpret this in the old way by the old notion of poles. The electro-magnet has two poles, and these excite induced poles in the opposite surface of the armature, resulting in attraction. If you double the distance from the pole to the iron, the magnetic force (always supposing the poles are mere points) will be one quarter, hence the induced pole on the armature will only be one quarter as strong. But the pole of the electro-magnet is itself weaker. How much weaker? The law of inverse squares does not give you the slightest clue to this all-important fact. If you cannot say how much weaker the primary pole is, neither can you say how much weaker the induced pole will be, for the latter depends upon the former. The law of inverse squares in a case like this is absolutely misleading.

Moreover, a third effect comes in. Not only do you cut down the magnetism by making an air-gap, but you have a new consideration to take into account. Because the magnetic lines, as they pass up through one of the air-gaps, along the armature down the air-gap at the other end, encounter a considerable reluctance, the whole of the magnetic lines will not go that way; a lot of them will take some shorter cut, although it

may be all through air, and you will have some leakage across from limb to limb. I do not say you never have leakage under other circumstances: even with an armature in apparent contact there is always a certain amount of sideways leakage. It depends on the goodness of the contact. And if you widen the air-gaps still further, you will have still more reluctance in the path, and still less magnetism, and still more leakage. Fig. 33

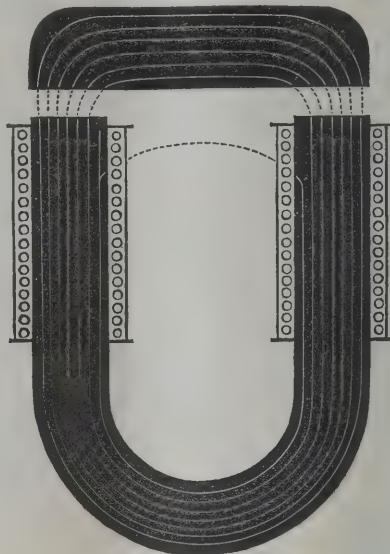

FIG. 32.

ELECTRO-MAGNET WITH AIR GAP ONE MILLIMETRE WIDE.

roughly indicates this further stage. The armature will be far less strongly pulled, because, in the first place, the increased reluctance strangles the flow of magnetic lines, so that there are

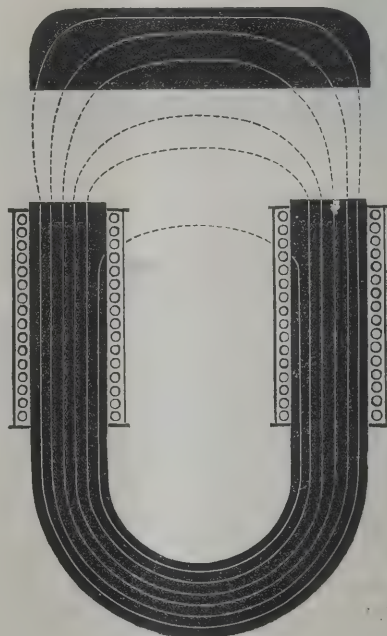

FIG. 33.

fewer of them in the magnetic circuit; and, in the second place, of this lesser number only a fraction reach the armature because of the increased leakage. When you take the armature entirely away, the only magnetic lines that go through the iron are those that flow by leakage across the air from the one limb to the other. This is roughly illustrated by fig. 34, the last of this set.

Leakage across from limb to limb is always a waste of the magnetic lines, so far as useful purposes are concerned. Therefore it is clear that, in order to study the effect of introducing the distance between the armature and the magnet, we have to take into account the leakage; and to calculate the leakage is no easy matter. There are so many considerations that occur as to that which one has to take into account that it is not easy to choose the right ones and leave the wrong ones. Calculations we must make by-and-bye—they will be added as an appendix to this lecture—but for the moment experiment seems to be the best guide.

I will, therefore, refer, by way of illustrating this question of leakage, to some experiments made by Sturgeon. Sturgeon had a long tubular electro-magnet made of a piece of old musket barrel of iron wound with a coil; he put a compass needle about a foot away, and observed the effect. He found the compass needle deflected about  $23^\circ$ ; then he got a rod of iron of equal length, and put it in at the end, and found that putting it in so

that only the end was introduced—in the manner I am now illustrating to you on the table—the deflection increased from  $23^{\circ}$  to  $37^{\circ}$ ; but when he pushed the iron right home into the gun barrel, it went back to nearly  $23^{\circ}$ . How do you account for that? He had unconsciously increased its facility for leakage when he lengthened out the iron core. And when he pushed the rod right home into the barrel, the extra leakage which was due to the

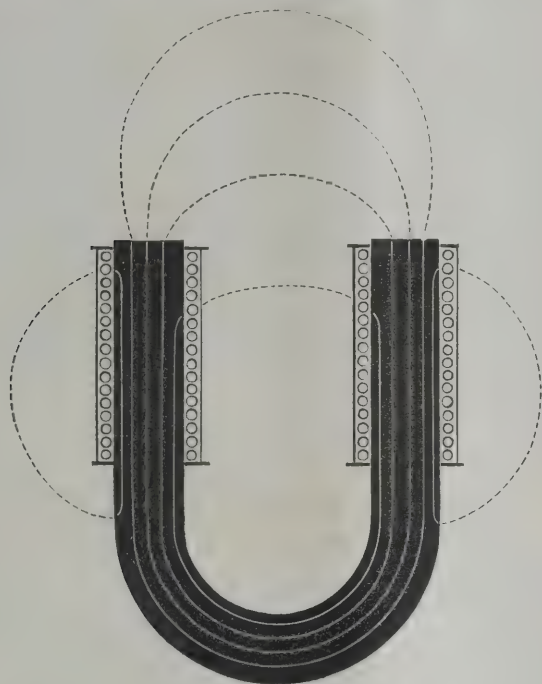

Fig. 34.

added surface could not and did not occur. There was additional cross section, but what of that? The additional cross section is practically of no account. You want to force the magnetism across some 20 inches of air which resists from 300 to 1,000 times as much as iron. What is the use of doubling the section of the iron? You want to reduce the air reluctance, and you have not reduced the air by putting a core into the tube.

(To be continued.)

## BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—LEEDS, 1890.

### NOTES ON HIGH VACUA.

By J. SWINBURNE.

(Read before Section A, September 9th, 1890.)

#### I.

IN a series of papers on "Incandescent Lamp Manufacture," I called attention to the great superiority of the Geissler to the Sprengel form of mercury pump. Several kinds of Sprengel pump were successively connected to a Geissler, and both were worked at the same time. The Sprengel invariably stopped taking air down before the Geissler; in fact, the Geissler never stops. It acts as its own McLeod gauge, and never indicates a perfect vacuum. The probable reason why the merits of the Geissler have been so underrated is that it needs the greatest care in securing perfect dryness of the bulb and valve. Not only will traces of water vapour condense under the floating valve instead of lifting it and going through, but it is probable air does so too. About a century ago Davy showed that if the mercury were allowed to run up gently in an imperfect Torricellian vacuum, a bubble was left; but if allowed to rise suddenly, it indicated a perfect vacuum, the air being condensed against the glass. In the lamp papers I described a form of pump which avoids difficulties due to small condensations. The main bulb discharges into a small chamber sealed by a little V-tube, so that a pressure of  $1/100$  A would move the mercury. This chamber exhausts into a larger globe, exhausted mechanically, and sealed by a floating valve. The small chamber is thus as thoroughly exhausted as an ordinary pump can pump it; but the pump proper, exhausting into high vacuum, can thus work better. The condensed air and water cannot expand back into it. It is thus really a double pump, or two mercury pumps in series. The only drawback is that it needs some pressure to open the first valve or sealing, so that there might, after all, be some condensation under it. I have lately devised and used a pump made as follows:—A, is the body or chamber of the pump proper. This exhausts into the small chamber, B, sealed by the valve, C, and this exhausts into the chamber, G, sealed by the floating valve, H. G is connected to a reservoir and mechanical air pump.

The valve, C, has a long thin glass rod passing down through A into the lower tube, which acts as a guide. A loose sleeve, F, is strung on this rod. There is a swelling at E which fits the lower end of the sleeve, and is small enough to pass through the neck in putting the pump together. When the mercury rises in the globe, A, it lifts the sleeve till the lower end catches on E, which closes it. The mercury rises, and floats the sleeve, thus lifting the valve, C. The mercury that sealed C, then runs out, and there is a clear passage through into B; so no condensation takes place in A. The mercury rises till it floats H. When it falls, the valve, C, acts again, for the mercury has filled the sleeve, F, over the top, and C is heavy enough to sink the sleeve and rod when the sleeve is full of mercury. I have tried electromagnetic and other arrangements; but this is the best, as far as I have gone.

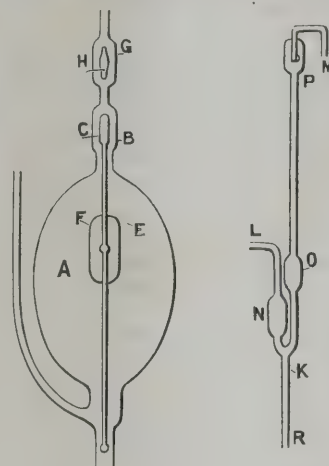

Fig. 1.

Fig. 2.

When using a pump it is best not to let air, and perhaps moisture, run through it more than can be helped. By the use of a sort of syphon it is possible to seal on new work to be exhausted without letting the air pressure into the pump.

The point, K, is the barometric height at which the mercury normally stands in the tube, R. There is then a clear passage between L, which is connected to the tubes to be exhausted, and M, which goes to the drying tubes and pump. When a tube has been sealed off and a new one is to be put on, the mercury reservoir at the foot of the arrangement is raised so that bulb, N, is filled. A tap at the foot of the tube, R, is closed, and the vacuum in L is broken. The mercury then runs up to the new barometric height, R. The new tube is then sealed on and exhausted by a mechanical pump, the connection being then sealed off. The mercury in the long tube then stands only half an inch or so above that in N, and on opening the tap at the foot of R, the communication is made again to the pump. The small bulb, O, and the trap at the top are to prevent a plug of mercury from going round into the phosphoric tubes.

The pump is driven by water so as to be self-acting, and can be left running for any length of time. Those who have worked much with mercury pumps will realise the value of this. Nothing makes one feel the futility of life more than to exhaust something by hand which cracks at the last stage, when five hours of life have been ticked off.

#### II.

IN the same papers on lamp making I urged, that [the methods of measuring high vacua were inaccurate and completely misleading. The McLeod gauge and the induction coil are usually relied on for testing vacua. In incandescent lamp work the induction coil is almost exclusively used. With the test by induction sparks, I have, at present, nothing new to add, and will confine myself to the McLeod gauge. In measuring vacua with this gauge it is assumed that the mercury itself has no vapour tension. The vapour tension of mercury has been given by Regnault as about 50 millionths of an atmosphere. If it is anything like this, of course a vacuum of one millionth, or of  $\cdot 005$  millionth, as some experimenters profess to have reached, is absurd. When discussing this subject at the Society of Arts after Dr. S. P. Thompson's well-known paper on "Mercury Pumps," Prof. Ramsay gave  $\cdot 25$  millionth of an atmosphere, or, as I shall write it shortly,  $\cdot 25$  m., as the vapour tension of mercury at ordinary temperatures.

The whole action of a pump is consistent with a vapour tension of from 25 m. to 50 m. A Geissler does not reduce the pressure in geometrical progression; but when it gets a good vacuum it takes out very little air each stroke, worked fast, and much more if worked slowly. This looks as if when the tension of mercury vapour was nearly reached, the air taken out at each stroke was what diffused into the mercury vapour. This would also explain why a Geissler, which goes on long after Sprengel stops, does not so readily make a sparkless tube. A Sprengel stirs up the mercury, and gives the tube being exhausted more chances of getting filled with mercury vapour, which is a non-conductor. This also explains why so many experimenters get better vacua with hot mercury. Of course a new pump should be heated to get the moisture off the glass, but not when it is in ordinary use.

To test this more directly, I attached two McLeod gauges to the same pump. They communicated till a fair vacuum was reached. One was then sealed by raising the mercury past the elbow tube. The gauges were allowed to communicate by lowering the mercury every now and then, and it was always lowered before taking a reading. By this arrangement, when the pressure was reduced nearly to the vapour pressure of mercury, one gauge might have little but mercury vapour, and show a good vacuum; while the other had air at the same pressure, and showed a pressure equal to the vapour tension of mercury, or nearly so. The gauges are graduated by finding  $p \cdot v$  corresponding to one millionth of an atmosphere, and graduating accordingly. The pressure in millionths is then the product of the reading on the closed tube and the difference in the column. Each reading is thus readily taken at several pressures to make sure there is no condensation of any vapours or gases. The readings obtained varied in an extraordinary way. When the exhaustion was carried so far that the open gauge registered 2 m. or 3 m., the closed registered from 20 m. to 60 m. The least difference in temperature seems to make a large difference in the readings. In some cases, when the vacuum was still low, the open gauge was heated till the mercury sputtered, and condensed about the bulb. The bulb was then warmed to evaporate the mercury and drive all the air out, and the elbow tube sealed by raising the mercury. When the gauge was cool both were unsealed and readings taken. The gauge that had been warmed sometimes gave 1 m. against no less than 230 m. in the other. Ten minutes' connection generally brought the readings equal. Obviously the movement of the air need not depend on diffusion only; for a very small difference of temperature would cause mercury to evaporate in one gauge and condense in the other, driving the air with it.

I made a gauge with an alloy of about equal parts of potassium and sodium, which is liquid at ordinary temperatures. It would, of course, absorb any mercury vapour, and has probably a low-vapour tension. It was very troublesome, for it could not be exposed to the air for a moment, and heavy hydrocarbons would prevent the pump's working. The alloy always gets some moisture, and gets coated with a thin film of oxide which prevents drops from uniting, and they can only be run together by heating under a hydrocarbon of low boiling point. I eventually got the gauge fitted up, but the alloy acted on the film of moisture on the glass, and the bubbles formed seemed to drive plugs of it about. It has a very low specific gravity, and pistons of it began to stray about inside the pump, and I was afraid they might get to the mercury, and by combining explosively, smash the pump, so the experiment was abandoned. In one experiment a plug did wander into the tube, &c., and cracked it.

Fusible alloy was next tried. It worked better, but the vapours of some sulphur that was used to trap any mercury vapour blackened the surface, and only two readings were obtained. These gave a pressure of only 13.5 m. as the vapour tension of mercury.

Whether it is really 13 m. or 50 m. is of comparatively little importance; but there seems to be quite enough evidence that the readings of .01 m., and higher vacua that have been given, are inaccurate to the extent of some hundreds of thousands per cent. This is important in many investigations pursued by means of mercury pumps, for instance, experiments on the "Fourth State of Matter." The question is also important in lamp making, as it shows that better vacua are possible, and they may be an advantage. I do not know whether pumps worked with alloy of sodium and potassium will come into commercial use.

#### DISCUSSION.

LORD RAYLEIGH considered the points that Mr. Swinburne had brought before the Section were of great interest. He had not had much experience in obtaining the highest vacua, but he had a good deal of experience with the mercury pump. He had been astonished with the immense quantity of vapour which hung about. At one time he passed a large quantity of air slowly over the mercury and then through a sulphur tube, and it would astonish most people to see what the discolouration of the sulphur was from the mercury vapour carried over the area. The points as to the behaviour of the McLeod gauge as the only available method for measuring the vacua were of the highest importance, and in conclusion he hoped Mr. Swinburne would not slacken his efforts to arrive at the bottom of the matter.

#### THE COMPENSATION OF ALTERNATING-CURRENT VOLTMETERS.

By J. SWINBURNE.

(Read before Section A, September 9th, 1890.)

In 1887 I had the honour of bringing before this Section several methods of compensating voltmeters and resistance-bridges for variations of temperature. Wires with different temperature co-efficients were used, by which means errors from change of temperature can be avoided. Methods of compensating wattmeters for the errors inherent in them were also explained. The present communication relates to a somewhat analogous arrangement for compensating alternating voltmeters for changes of frequency.

It is much more easy to make a current indicator for alternating than direct currents, for troubles from hysteresis do not come in, and the slight tremble makes the moving part hang freely. If it is attempted, however, to use such an instrument as a voltmeter, the self-induction makes the reading far too low, and the error varies with the frequency.

To get over this trouble, a voltmeter may have a non-inductive, or nearly non-inductive, resistance put in shunt to its active coil. A coil with an adjustable iron core is then put in shunt to the active coil, this shunt coil having a very much larger time-constant. Though both coils have iron cores, they have open magnetic circuits, so they have practically constant co-efficients of self-induction. When the frequency increases, the current through the whole instrument under a given pressure falls; but the back pressure of the shunt coil increases more rapidly than that of the active coil, so that it takes less than its share, while the active coil gets a larger share of the reduced current; the actual current, and therefore the reading, in it remaining constant. The instrument is calibrated with a direct current. An alternating current is then put on, and the core of the shunt coil regulated till the readings agree with those of the direct current.

A similar effect might be obtained by putting a condenser in shunt to the non-inductive series resistance; but it does not look so promising, and I have not gone into the size of condenser needed in practice.

#### LONDON COUNTY COUNCIL.

THE weekly meeting was held at Spring Gardens, S.W., on Tuesday last, with Sir John Lubbock in the chair. The Asylums Committee, in bringing forward their report, stated, with reference to the Claybury Asylum, it had been decided to light it by electricity. In order to do this, they had referred it to one of the assistants in the engineers department to prepare and formulate a scheme for that object. It would be necessary for the purpose to expend a sum of money for the preparation of plans, the employment of temporary draughtsmen, and, possibly, for consultation with an expert. In conclusion, the committee recommended that a certain sum of money should be devoted to the object.

## ABSTRACTS OF PUBLISHED SPECIFICATIONS 1889.

10640. "Improvements in electric arc lamps." T. P. C. CRAMPTON and A. ESSINGER. Dated July 1. 8d. Claims:—1. In combination with the lower carbon holder tube, a crown piece at its top carrying several refractory studs, and a weight urging upwards a conoidal piece of insulating material supporting the carbon, so that the coned point of the carbon is retained in position as it is consumed by bearing against the studs, against which the conoidal insulating piece is made to bear when the carbon is exhausted, substantially as and for the purpose set forth. 2. In combination with the upper carbon holder tube having attached to it a core subject to the differential attraction of two solenoids, a clutch consisting of jaws which grip the carbon until, by the descent of the tube a certain distance, they meet adjustable stops whereby they are released, allowing the carbon to slip downwards, substantially as described. 3. The combination of a lower carbon holder such as is referred to in the first claim, and of an upper carbon holder and clutch such as is referred to in the second claim with suitable solenoids and framing, constituting an electric arc lamp, substantially as described.

12185. "An improved mode of and apparatus for distributing electricity." A. H. HOWARD. Dated July 31. 11d. Claims:—1. In a system of electric distribution from a central station, through storage batteries situated at various points on the external circuit, the use, at the central station, of a periodically acting automatic switching apparatus, for diverting (temporarily) the entire dynamo current from the batteries in charge, to a resistance, and allowing mechanism situated at the various storage stations on the line, to come into action and effect the changes in the local circuits, as and for the purpose above described. 2. In combination with the storage batteries at each installation, a rotary commutator arranged to effect a cycle of changes in the connection of the batteries with the line wire, and with each other, as and for the purpose above set forth.

12236. "Improvements in appliances for distribution of power by alternating and commutated electric currents." J. SWINBURNE. Dated August 1. 8d. Transformers are used to transform alternating currents, and these alternating currents are, when desired, combined to form direct currents, and may themselves be produced by the commutation of direct currents. 5 claims.

12237. "Improvements in and connected with electric transformers." J. SWINBURNE. Dated August 1. 8d. Two or more transformers are used for each house, and are put into or out of circuit by automatic gear as required. Thus a 100-lamp house may have a 90 and a 10-lamp transformer. The 10-lamp transformer is ordinarily in circuit, but when the current rises to that of 11 lamps, an electro-magnet or other suitable mechanism cuts the primary and secondary of the 90-light transformer into circuit. When no lamp is used the mechanism may be arranged to cut out even the 10-lighter, and leave in a minute transformer just big enough to work the mechanism. 5 claims.

12503. "Improvements in dynamo-electric machines." F. V. ANDERSEN. Dated August 7. 8d. Has for its objects to construct the brushes by which the current is taken off or conducted to a dynamo-electric machine of an improved shape and in an improved manner. The brushes are constructed in the shape of an arc of a circle, and are manufactured by winding copper or other wire, or conducting strips or tape, into a round reel, and soldering the wire or strips or tapes together at as many places as the number of brushes intended to be cut out of the reel, and, finally, cutting the reel into the intended number of pieces, so that a soldered portion is at or near one end of each piece, and the other end is unsoldered. The brushes are arranged in such manner that the end that comes in contact with the commutator is radial to it. 4 claims.

13553. "Improvements in and in connection with electrical signalling apparatus for preventing collisions between trains on railways." E. EDWARDS. (A communication from abroad by T. Verls, of Würzburg.) Dated August 27. 8d. This invention has for its object the prevention of collisions between locomotive engines or trains travelling in the same or opposite directions upon the same line of rails, and also to give notice at the right time of the threatening danger to the drivers of both locomotives by means of electrical bells. 3 claims.

## CORRESPONDENCE.

### Electricity Meters.

In your last week's issue under "Meters" in your Notes, I see with much interest that there are 515 electricity meters in use at the Geneva Central Station.

Permit me to say with regard to your concluding remark that I do not think it in the least doubtful that this total is largely exceeded in the London central stations. This company alone, for instance, has 206

electricity meters in daily operation, all of the Aron type, with one exception, and over 17,500 lights.

The Kensington and Knightsbridge Company, St. James's and Pall Mall, Westminster Company, and others will at least make the total reach 1,000, and to this would have to be added the meters on the alternating systems.

W. Howard Tasker,

Electrician Chelsea Electricity Supply  
Company, Limited.

October 21st, 1890.

In the last issue of your esteemed paper, on page 463, you mention under the heading "Meters," that 450 Aubert meters and 65 Aron meters are in operation at the Geneva Central Station. You conclude the leaderette with the question, "*We wonder whether London with all its central stations can total 515 meters in use?*"

Will you allow us to draw your attention to the fact that the Aubert meter is not an electricity meter like the Aron meter, but simply a primitive arrangement for counting the "lamp hours," consequently it does not come up to the standard which is expected in this country for meters.

As regards the number of meters in use in London, we cannot say positively how many meters of the various types are in actual use, but it may interest you to know as a positive fact that we have sold the following number of Aron meters:—

For the year 1887	...	...	...	26
" " 1888	...	...	...	69
" " 1889	...	...	...	354
" " 1890 up to date	...	...	...	721

And we have booked orders within the month of October for close on 1,100 Aron meters to be delivered during the coming season, most of which are for London.

The General Electric Company, Limited.

H. HIRST, Director.

### The Lane-Fox Patents.

Now that "The Lane-Fox Electrical Company" is showing some fresh signs of vitality by bombarding the unfortunate "consumers" of electric light with mysterious manifestoes, threats of writs, *et hoc genus omne*, it would be useful, I think, if some of your more initiated readers would throw a little light upon this matter. Many good people, I fancy, have either forgotten Mr. Lane-Fox and his inventions, or are now hearing of them for the first time. Upon such minds the question "What is the Lane-Fox system?" has very much the same effect as the old riddle, "Who's Griffiths?" with which in my early youth the walls and hoardings of London used to be placarded. Is Mr. Lane-Fox also the Safe Man?

Mystified.

October 22nd, 1890.

### Running Alternators Parallel.

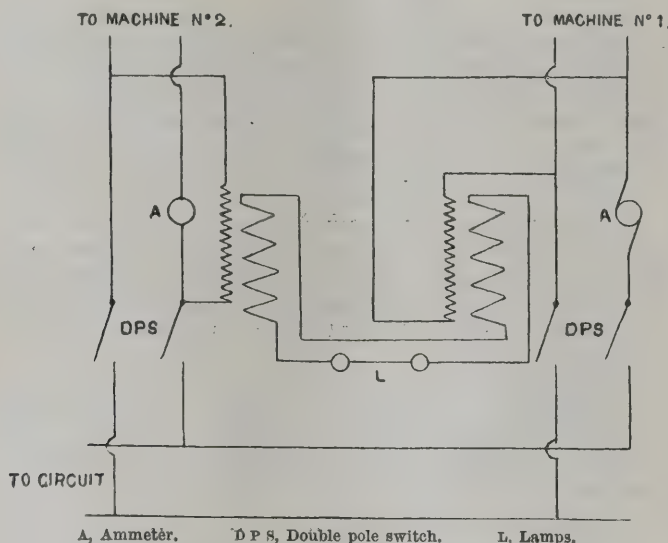

It may interest your readers to know that during the past few days we have tried running the Mordey alternators here in parallel. The results have been in every way satisfactory.

As we had no synchroniser, we joined a transformer to each of the two machines, and put the secondaries in series with two incandescent lamps, so that when the two machines were in phase, the lamps were bright as with an ordinary synchroniser. We tested the transformers for this by so connecting them both to one machine, that the lamps in series were bright with the secondaries in series. We then transferred the primary wires of one transformer, so as to connect it to the corresponding poles of the other machine,

We send you sketch of the connections. From these you will see that any current passing from one machine to the other is registered on both ammeters.

The machines were first put parallel when the load on the one supplying current to the outside circuits was only 5 ampères. They went into step at once and kept so. The current going between the machines to keep them in phase was not sufficient to make the needles swing more than 2 ampère divisions on the ammeters.

The load was transferred to either machine quite easily by speeding its engine up slightly by means of its governor.

The second dynamo was switched out of and into circuit several times as the current increased. They were run parallel till after the heavy load of the evening (about 40 ampères) was passed, each machine taking half the work.

During the heavier loads, the swing of the needles was greater, showing that more current was being sent between the machines; but this would correspond to only 3 or 4 ampères.

When the load dropped under 30 ampères, the load was transferred to one dynamo, and the other switched out of circuit.

We have also made the experiment of switching the machines in parallel when not at the same voltage. The difference was about 3 per cent. The current which flowed between them was 10 ampères. This seems to indicate that a very large current indeed must have passed when Mr. Mordey made his experiment of putting a machine at 1,000 volts in parallel with one at 2,000 volts.

George S. Hooker, *Electrician.*

Bath Electric Light Works,  
October 15th, 1890.

#### Accumulator Management.

Will Mr. Barber-Starkey kindly oblige by letting me know how much soda (common washing, I believe) should be put to one gallon of solution—1 to 10 for accumulators. I have lately bought some second-hand cells. Some give a good current after charging and others comparatively little, though all look much the same in colour. What is likely to be wrong, and how can I remedy it?

I have already tried some soda, adding it to the solution, which hissed up until it was dissolved; but considerable sulphate still remains.

B. B.

#### Telephonic Specific Inductive Capacity.

In an article under the above heading in your last issue, Mr. W. W. Jacques points out that there is a considerable difference between the telephonic and the

telegraphic specific inductive capacity of certain materials.

After describing some experiments made by himself and others upon various dielectrics, he gives a table showing that the telephonic capacity of all the samples tried, except one, is HIGHER than the telegraphic capacity of those samples.

Surely this is not quite correct.

All theory and practice, except Mr. Jacques's, so far as I am aware, tend to show that the capacity of any dielectric is LESS when measured by currents of short duration—*e.g.*, telephonic currents—than when measured by currents of longer duration, *e.g.*, telegraphic currents, owing to the "absorption effect" noticeable when any dielectric is charged for an appreciable time.

This is clearly explained in most text-books upon the subject, and is noticed even in the authority quoted by Mr. Jacques, *viz.*, "Gordon's Electricity and Magnetism," chapter 11. On pages 99 and 103 of the second edition, experiments are described and figures given which clearly show that Mr. Jacques's deductions are not correct.

Again, on page 109, we read: "*The capacity increases if the electrification is continued—at first rapidly, then more slowly,*" &c.

As the question is of considerable importance in long distance telephony, and, as an earlier edition of the same article has been published in your Journal of 21st March last, page 314, without any one drawing attention to the inaccuracy of the results contained therein, I think an explanation is due from Mr. Jacques as to how his experiments were made, and also as to how he arrives at the "calculated results" given in the middle column of the table referred to.

J. W. Ullett.

October 21st, 1890.

On 28th March last you were good enough to publish a letter from me on the subject of telephonic specific inductive capacity, and in your Editorial columns you remarked that when Dr. Jacques had read the letter you would probably receive a disclaimer from him. The article by Dr. Jacques quoted in your last week's number from the New York *Electrical Engineer* is mainly a republication of the communication which I criticised, but with the omissions I claimed should be made. It seems to me that the article contains internal evidence that Dr. Jacques has read my letter, but I have not noticed any disclaimer in your columns.

Perhaps another reminder would bring it about.

J. E. Kingsbury.

October 21st, 1890.

#### Accumulator Explosions.

Having read the account of the extraordinary accident which took place on board Earl Poulett's steam yacht, the *Pathfinder*, I think the occurrence, though fortunately uncommon, may be easily accounted for on the supposition that during the violent storm of rain when the leak was reported, water must have collected somewhere near the main conductors, or some uninsulated portion of the system, and have been decomposed, liberating hydrogen; and a sufficient quantity of this gas, in conjunction with the atmospheric air would naturally and immediately explode on a light being struck. Therefore this mishap need in no way be attributed to the use of accumulators, as it seems they were properly ventilated, and such accidents may be readily prevented by taking care to duly protect and insulate the flow and return conductors, and other exposed portions of the system from each other.

H. Edmunds.

## THE LANE-FOX PATENTS.

IN our present issue we print a somewhat lengthy letter from Mr. St. George Lane-Fox; but we fail to see that he has answered the various points that we raised. We think that he passes too lightly over the demonstrations and work of others previous to 1878, the date of his first patent, and although these experiments may have been mainly with lamps made of platinum wire or strip, yet that would not alter the principle of running such lamps in parallel or series, as might be desired, there being no invention in the arrangement. For such modifications would have occurred to anyone who was studying the subject; and as two horses might be driven either abreast or in tandem, so lamps might be connected up either in series or in parallel arc. Long before Mr. Lane-Fox commenced his researches, it was a common practice to connect up primary batteries in series for tension, and in parallel arc for quantity, and therefore the principle of such arrangements were well-known to electricians. Prof. Moses G. Farmer, in discussing his experiments at Salem, Mass., in 1859, remarks:—

“If a wire of pure platinum 5 inches long and  $\frac{1}{160}$ th of an inch in diameter be traversed by a current of electricity, somewhat more than five and less than six vebers in strength, it can be maintained at a temperature quite near to the point of fusion, and while in this condition it will, in the common atmosphere, emit something more than three candle lights, and just below the melting point, the light will be between four and five candle lights.

“Now, if 100 such wires be put in series in a circuit, the sum of this resistance would be 125 ohms, and it would require a difference of potential equal to  $125 \times 5\frac{1}{2} = 687\frac{1}{2}$  volts to maintain this strength of current of  $5\frac{1}{2}$  vebers, and we should get in the aggregate 500 or more candle lights.”

Mr. Lane-Fox may object that this only refers to the running of lamps in series, and the maintenance of current for that purpose. But mark what follows:—

“If, further, we should arrange 10 such circuits in multiple arc, having 100 lights in each of the 10 branches, we should find the joint resistance of this part of the circuit reduced to  $12\frac{1}{2}$  ohms; but it would now require a current of 55 vebers’ strength to keep the lamps all shining and the difference of potential required to maintain the 1,000 lights, each from three to five candles, would still be  $687\frac{1}{2}$  volts; but we should now have 5,000 candle lights instead of 500.”

Therefore, it is quite evident that the laws which govern the running of incandescent lamps in parallel were clearly recognised many years before the advent of Mr. Lane-Fox.

With regard to the *only* claim for which Mr. Lane-Fox says he is now endeavouring to obtain recognition (*viz.*, for a system of combining incandescent lamp distribution in multiple arc at a constant potential, with secondary batteries as reservoirs of electrical energy); if this patent entitles him to the combination with a reservoir, why is he not entitled to the running without a reservoir? This would mean that any mode of running two or more lamps in parallel, whether from dynamos, accumulators, or thermopiles, would be included in his system. On the other hand, it would seem that the addition of the battery was the invention that Mr. Lane-Fox claims, and therefore he might as well claim the discharge from the battery as distinct from the dynamo. As, however, he does not go into details, and ignores the work of earlier pioneers, we can hardly call his methods discoveries or inventions, as they were simply the obvious arrangement of parts, the parts themselves being the patentable matter, and not their re-arrangement.

One thing, however, is quite clear: secondary batteries can still be used without infringing Mr. St. George Lane-Fox’s claim if employed for discharging when disconnected with an operating dynamo. On this point some doubt has been expressed, but we have it from the inventor himself that it is only when used simultaneously with a dynamo that he makes any demur, for it is well known that Werdermann con-

nected his lamps up in parallel arc, the potential being constant, or as nearly so as was possible with the machine employed to generate the current.

With regard to the Brush Company, they would naturally have no interest in contesting the validity of Mr. Lane-Fox's patents while they held them; and when they were relinquished the Brush Company retained the right of working under them, so that any license granted under those circumstances would only be a matter of form, and could not be construed as a surrender to Mr. Lane-Fox's claims.

Why should Sir David Salomons be quoted? He simply shows that primary batteries, as usually made, have so high an internal resistance that any alteration in the work they are doing causes a variation of their potential. With a very large battery, however, the internal resistance would be small in proportion, so that less variation would be apparent. But the term "constant potential" is only a comparative one, and, should the work the battery is doing be out of proportion to its size, the potential would again be irregular, as in a primary battery. Thus it is wholly a question of proportioning batteries to their work, whether they be primary or secondary.

We have every desire to set the views of the contending parties clearly and fairly before our readers, and for this purpose we feel ourselves justified in asking Mr. Lane-Fox for a further explanation and a reply to our remarks of last week.

---

## FOR ELMORE SHAREHOLDERS.

---

IN bringing our articles on the Elmore Companies to a conclusion, we may remind our readers that we were somewhat sceptical when the first companies were issued, but it was hardly possible to foresee the later developments. Company following company naturally aroused our suspicions, and we protested, as we were bound to do. The results of our enquiries on the various points are before our readers, and speak for themselves, so that we need not say whether we consider our suspicions to have been confirmed or not.

We know that the promoting instinct is prone to follow up an initial success with ventures of the same kind, and the success of the first company was a temptation to repeat the operation which could not, apparently, be resisted. The issue of the Austro-Hungarian prospectus has been the last, and though there is little room for doubt that there were more to follow, it is satisfactory to know that no other has since been issued. We have no exaggerated idea of our contribution to this result. We do not anticipate that our electrical friends are amongst those who would rush in for Elmore shares, and the general public do not read technical papers, or seek in them information upon topics which come within their province. All the same, we have felt it to be our duty to speak out for the benefit of any investor whom per-

chance our words might reach, and for the credit of the electrical profession.

We have spoken out, and having done so we will say nothing more of the past, but deal with the present and the future.

To the shareholders of the subsidiary companies we venture to repeat the advice which we gave before. Keep the money you have in hand, and don't proceed with the work set out for you until the parent company has shown that there is a commercial success in the Elmore process. There is nothing unreasonable in this. All that will be lost is time, and that can be made up with the good start which the experience of the parent company will give you. There is no reason to suppose that France and Austria are so hungry for Elmore copper that by a few months' delay a market may be lost never to be regained. Energy, enthusiasm and enterprise are very well in their way but we recommend a strong infusion of caution as well.

To the shareholders of all the companies we would say: Remember that it is not an unusual thing for a company to embark in an enterprise with which it is found undesirable to proceed, and thereupon to take up something else. Articles of association are wide enough to permit very varied occupation for the employment of the capital subscribed. Sometimes this diversion leads to success, but too often it means that, however little the directors know of the business for which the company was originally formed, they know less about the second string, with the result that disaster comes at last.

To the parent company, we would say: You have received valuable consideration for the rights with which you have parted, and it is your duty to carry the process to a successful conclusion if you can, but not necessarily to throw good money after bad if your expectations of a Golconda show unmistakeable signs of being misplaced.

Inventors are expected to be sanguine, but to the promoters more than the usual responsibility attaches, on account of their well-known connection with the electrical business, and the pledges which they have given that their thorough examination of the system had satisfied them of its value.

Of the process itself we have written with the best information at our disposal, and, in considering that information, have used our best judgment. We shall, if proved to be wrong, cheerfully withdraw any unkind things we may have said about it. But successful or not successful, we shall not alter our opinion of the un wisdom of floating a series of companies and paying away large sums of money for an undeveloped and comparatively unprotected process whatever its problematical prospects.

To electricians the electro-deposition of copper on a large scale is in itself a matter of considerable interest. To a number of subscribers understanding the risk they run and being prepared for either success or failure, and the inventor depending on results for his remuneration, it would have been a legitimate enterprise; we could then have encouraged it and watched with interest the results attained,

The Labour  
Question.

WE mentioned in a former number that our rules respecting anonymous correspondence compelled us to deny admission to our columns of a letter signed "S. T. E.," purporting to be a reply to our article of October 10th, on the labour question. But so that "S. T. E." may not be under the apprehension that the waste paper basket has been the destination of his letter, we will devote a few words to a brief review of the contents of his communication. In the course of a somewhat rambling series of assertions and contradictions, making it uncertain whether "S. T. E." upholds the conduct of the unionist or appeals on behalf of the working man in general, our correspondent upbraids us with having employed the epithets "bully," "sneak," and "perverter of the truth," as being descriptive of the general characteristics of the unionist. We would refer "S. T. E." to the history, as recorded in the police courts and hospitals, of every strike which has taken place, and would then ask him if the conduct of unionists and the treatment of non-unionists, do not emphatically bear out the justice of our language. Our correspondent in the all engrossing desire to support the cause of those with whom he sympathises, lends his own voice to swell the war-whoop of "capital *versus* labour," and indulging in a diatribe against capitalists, so heats his fancy, that he entirely misses the whole point and intent of our article, which certainly did not make the question one of class *versus* class, an issue which "S. T. E." would apparently provoke. "S. T. E." censures our expression of opinion as being "unavailing and harmful," "as it is generally false." He does not, however, attempt to support this contention by either argument or evidence, but pretends to find, in the action of employers to maintain the rights of free labour, an evidence of the tyranny of capital over labour, and a palliation of ill-advised and ill-directed proceedings. From the general tone of the communication we should guess the author to be a well-meaning, but very young, enthusiast. Some further study of the subject may, however, show him that indiscriminate strikes must result not only in a loss to the employer, but eventually in much graver consequences to the workman; and he may learn that the attempt to coerce either capital or labour, must end in disaster to all classes of the community.

## Bahamas Cables.

THE rapidity with which news is now-a-days diffused is marvellous, and in no less degree have we cause to wonder at the extraordinary fertility of invention evidenced in the contents of the daily journals. It is a common enough event to read very exact particulars of occurrences, when the persons who are presumably most interested, are entirely ignorant of their having taken place. We extract the following from the *Evening News and Post*:—"That so important a colony as the Bahamas should be unconnected by cable with the rest of the world is a singular fact. Quite recently the neighbouring colony of Bermuda has obtained a cable, but at the almost prohibitive tariff of 4s. 2d. per word. Better things have been done for the Bahamas, as we understand on good authority that the India-rubber and Telegraph Works Company of Silvertown, are about to lay a cable from Jebrida to Nassau Bahamas, at the cost of £25,000, and that the money for this cable is being provided by the colony. The charge per word for England will be 2s. per word, with a half extra for official telegrams and a reduction for press news. The rate to America will be 6d. per word. The cable will be ready for use by the spring."

## A Quiet Rubber.

A CORRESPONDENT, who signs himself "Perplexed," sends us some circulars descriptive of the Bellhouse Patent Anti-Rheumatic Towel. The peculiarity of the towel is, that it is made from a fibre which generates electricity, but, unlike other known fibres, which absorb what they produce, that of "the anti-rheumatic towel, having a negative power, compels the body to absorb the electricity it generates from the part on which it operates." That a good rubbing with a friction towel is invaluable as a specific for rheumatic complaints is undoubted, but why the virtues of this particular toilet appliance should be attributed to a negative electrical power in the fibre we do not quite comprehend. Though the electrical explanation is utter rubbish and results either from ignorance, or intention to foist on the public by investing it with fictitious attributes an everyday appliance, it is quite possible that the rheumatic victim may be induced to rub harder with this towel inspired by the desire to see sparks or feel an electrical glow, whatever that may be. This would amply account for its efficacy and also throw light on the testimonials written in its favour by men of position and undoubted integrity. Imagination has much to do with these things; the old towel is played out and it offers but small inducement to rub; but make a man believe he is a sort of animated frictional machine and the influence is at once apparent. It acts like a charm and he rubs with tenfold vigour. Truly electricity is a name for both ignorant and enlightened to conjure by.

Lighthouse  
Illuminants.

THE recent report by Sir C. G. Stokes, Lord Rayleigh, and Sir W. Thomson on the subject of lighthouse illuminants seems to be somewhat contradictory to opinions which have been previously expressed by other observers as regards the efficiency of the electric light. It has been stated that, although in clear weather the electric light is far superior to gas or oil, yet in fog and haze it has but very little penetrating power, and that in such cases the glare of the large mass of flame from oil or gas can be seen when the electric light has wholly disappeared. The report in question, however, states that when the electric light has been deprived in great measure of the highly refrangible rays, in which it so much abounds, by passing through a sufficient length of haze, in its further progress it is not more cut down than the light from gas or oil, and the initial intensity is so great, that it still retains its superiority. Accordingly, the signatories to the report, in their conclusions, state that the experiments establish the superior power of the electric light as exhibited at the South Foreland under all conditions of weather, &c.

## The Microphone.

THE exact action of the microphone has never been really satisfactorily explained, although theories and experiments innumerable were for several years in succession brought forward to solve the mystery of its phenomena. Of late years little or nothing has been done in the matter, the all-absorbing interest in the electric light and its allied industries having diverted the stream of experimental and theoretical work. In a recent paper read before the American Academy of Arts, Prof. Charles R. Cross gives the results of experiments he has made relative to the "Extent of the Excursion of the Electrodes of a Microphone Transmitter." The method adopted for the researches was a stroboscopic one, a microscope magnifying up to 940 diameters being used. The greatest movement observed, consistent with good quality tones being obtained, was  $40 \times 10^{-6}$ . Interesting as the paper is, it still leaves us in the dark as to the way in which the movement of the electrodes causes a resistance variation.

ON THE EXTENT OF THE EXCURSION OF  
THE ELECTRODES OF A MICROPHONE  
TRANSMITTER.\*

By CHARLES R. CROSS, Thayer Professor of Physics.

THE character and extent of the motions of the electrodes of a microphone transmitter, when actuated by sound waves of different degrees of intensity, is a subject in telephony of by no means slight importance, but to which very little study has been given. The present paper describes the results of some observations relating to this subject, which have been made at various times during the past two years.

Several years ago an attempt was made by Mr. W. W. Jacques and the writer to gain some knowledge as to the amplitude of the vibrations of the hammer electrode of a microphone, by observing it with a microscope while in operation, and noting the extent of the blurred portion of the image. The results, though giving all that could be expected from so crude a method were not very satisfactory so far as definite measurement was concerned.

It afterwards occurred to the writer that the matter might be studied more completely by the use of the stroboscopic method, and an arrangement of apparatus was adopted by which the motions of the electrodes could readily be observed.

This was done in the following manner. The microphone to be studied was placed in the field of a microscope, whose line of collimation was horizontal. Behind the microphone, at a suitable distance, was placed a Helmholtz mercury interrupter, with a tuning fork making 128 vibrations per second. The extra current due to the electromagnets of the interrupter was quite large, so that a brilliant spark was obtained at each rupture of the circuit, as the platinum style of the interrupter left the mercury. The interrupter being properly placed, and the light of the spark concentrated by a lens, quite a bright field was obtained, against which the electrodes were seen projected, as silhouettes. The light, though intermittent, of course seemed continuous, since the sparks were so numerous. When good definition was obtained, the microphone was set in operation, usually by means of an organ pipe placed at a convenient and variable distance, and in some experiments by the voice. The pipe was blown by a constant blast, and great uniformity of intensity in the sound was secured. An open C<sub>3</sub> organ pipe making approximately 256 double vibrations per second was commonly used, its pitch being variable to a moderate extent by shading the mouth or the opening at the top.

So long as the pipe was an exact octave in pitch above the interrupting fork, the electrodes of the microphone as seen with the microscope appeared to be at rest; but if the interval was slightly disturbed, the stroboscopic effect was observed, and the electrodes seemed to move slowly through their complete course. The rate of this apparent vibration was of course dependent upon the deviation of the pipe from exactness in its interval with the fork, and could be varied at will within quite wide limits.

The extent of the motion of the electrodes could be determined by observing the grains of dust which adhered to them, or some definitely marked roughness on their surface. Measurements were made by means of a spider-line micrometer, the wires of which were placed at a convenient distance apart, and the amplitude of the motions of the selected points of reference on the microphone was determined by estimating the relation of their apparent motion to the distance separating the wires of the micrometer. This last distance was frequently varied to diminish the liability to error from a possible bias of the observer towards an agreement with earlier results.

In the experiments described in the present paper,

the electrodes were generally so adjusted that the motion of the anvil electrode was too small to be observed. Under these circumstances the observed motion of the hammer electrode, as measured by the micrometer, was the motion of this relatively to the anvil electrode, which is of course the quantity to be determined, rather than the actual excursion of the hammer electrode.

The microphone was placed in circuit with a battery and the primary of an induction coil, whose secondary contained a receiving telephone. With this arrangement the effect on the ear of the electrical variations due to the various values of the excursions of the electrodes could readily be observed. In many cases a second observer was stationed at the receiving telephone, which was then placed in a separate room.

Magnifying powers were used of from 50 to 1,000 diameters. With the higher powers the use of an objective of short focal length was difficult on account of the small working distance, so that, although even as short a focus as  $\frac{1}{10}$ th in. was sometimes employed, it was found much preferable to obtain the needed magnification by the use of short focus eye pieces.

The brilliancy of the electric spark was amply sufficient for illumination of the field, even with the highest magnification employed; a fact which calls attention vividly to the enormous "instantaneous intensity" (so to call it) of that light. Considering the excessively brief duration of the spark and the very small quantity of matter illuminated, it seems unquestionable that the intrinsic brilliancy is far greater than that of the electric arc, a view fully supported by the results of spectroscopic study.

Various forms of microphone were observed, but the general features characterising the actions studied were common to them all. As the intensity of the sound acting on the microphone was increased by approaching the organ pipe to the diaphragm, the motion of the hammer electrode, at first absolutely invisible, was seen gradually to increase, until, when the intensity was very great, the motion was excessive, the anvil electrode being violently pushed aside, and the hammer leaving it on its return motion, so that the circuit was broken at every vibration. At the same time bright sparks were seen between the electrodes. To the ear the simultaneous acoustic changes in the sound transmitted were very striking. The sound of the pipe was distinctly audible, and its quality clear, with motions of the hammer electrode far too slight to be observable. As the sound actuating the telephone became louder, and the excursion of the electrode became visible, the quality continued good, the sound transmitted growing louder; and then, as the excursion increased further, the quality gradually changed, shrill false notes made their appearance, and the sound began to grow harsher, until finally, when breaks appeared in the current, the sound was excessively harsh, and entirely devoid of musical quality. Long before this, however, the characteristic quality of the organ pipe disappeared.

The following tables will illustrate the results obtained. In making many of the measurements I worked in company with Mr. W. W. Jacques, whose observations were always in substantial accord with my own. A large number of observations have also been made, under my direction, by Messrs. A. W. Jones and F. L. Dame, students in the laboratory, whose work has been performed with conscientiousness and accuracy.

The microphone used in most of the experiments was one in which the anvil electrode was a "pendulum electrode," suspended by a vertical rod, hinged at the top, and so weighted as to give to it a proper mass. The desired normal pressure could be obtained by sliding the point of suspension laterally so as slightly to incline the supporting rod, and further, by adding a weight so as to exert a proper leverage, if this was desired. The hammer electrode was pointed and carried by the diaphragm, which was of mica. The sounding pipe was gradually removed from or approached toward the microphone. Care was in all cases taken to keep the wind pressure constant. A single

\* Read at a meeting of the American Academy of Arts and Sciences, April 9th, 1890. From the *Technological Quarterly*.

Leclanché cell was ordinarily used, though in a few cases a Grénet cell was employed.

In the various tables, the excursions of the electrodes are in all cases given in fractions of an inch. In designating the material of the electrodes, that of the anvil is stated first.

Tables I. to III. show the results obtained when both electrodes were of carbon; Tables IV. and V., when the anvil electrode was of carbon, the hammer of platinum. Tables VI. to VIII. contain results of observations made with a modified form of transmitter, in which the anvil electrode was also somewhat heavier than in the earlier experiments.

TABLE I.

ELECTRODES, CARBON, CARBON.—*Magnification, 50 diameters.*

Excursion.	Character of Sound.
$1000 \times 10^{-6}$ to $700 \times 10^{-6}$	Constant breaking and sparks. Electrodes visibly separating.
$600 \times 10^{-6}$	Constant sparking. Electrodes occasionally seen to separate.
$200 \times 10^{-6}$	Occasional breaks and sparks.
$200 \times 10^{-6}$	Scratchy sound, no sparks.
No visible motion.	Sound clear and smooth.

TABLE II.

ELECTRODES, CARBON, CARBON.—*Magnification, 50 diameters.*

Excursion.	Character of Sound.
$1000 \times 10^{-6}$ to $600 \times 10^{-6}$	Constant sparks; electrodes separating.
$300 \times 10^{-6}$ to $200 \times 10^{-6}$	Harsh; occasional breaks and sparks.
$150 \times 10^{-6}$	Scratchy.
No visible motion.	Clear and smooth.

Whenever the excursion of the hammer was greater than  $100 \times 10^{-6}$  the sound was very scratchy and harsh.

TABLE III.

ELECTRODES, CARBON, CARBON.—*Magnification 160 diameters.*

Excursion.	Character of Sound.
$350 \times 10^{-6}$ to $300 \times 10^{-6}$	Loud, noisy, harsh.
$250 \times 10^{-6}$ to $200 \times 10^{-6}$	Very scratchy.
$120 \times 10^{-6}$ to $80 \times 10^{-6}$	Scratchy, but less than before.
$150 \times 10^{-6}$ to $100 \times 10^{-6}$	Scratchy, but with high overtones.

At the lowest amplitude given in Table III. the quality of the sound of the pipe was first heard, but a still less amplitude was necessary for its satisfactory reproduction.

TABLE IV.

ELECTRODES, CARBON, PLATINUM.—*Magnification, 160 diameters.*

Excursion.	Character of Sound.
$250 \times 10^{-6}$	Constant sparks and breaks.
$120 \times 10^{-6}$	Scratchy; occasional sparks and breaks.
$70 \times 10^{-6}$	Raspy.
$50 \times 10^{-6}$	Quality distinct, but high squealing overtones present.
$20 \times 10^{-6}$	Quality better; fewer high overtones.
Less than $20 \times 10^{-6}$	Quality better; some high overtones still audible.

The pipe had to be carried twice as far away from the transmitter as in last measurement, to a distance of 18 inches, before the quality became really excellent.

TABLE V.

ELECTRODES, CARBON, PLATINUM.—*Magnification, 150 diameters.*

Excursion.	Character of Sound.
$120 \times 10^{-6}$	Very scratchy; occasional sparks.
$60 \times 10^{-6}$	Squealing, high overtones.
$40 \times 10^{-6}$	Fair quality; high overtones prominent.
$< 20 \times 10^{-6}$	Good quality; a little rough.
$400 \times 10^{-6}$	Constant breaking.
$60 \times 10^{-6}$	Very raspy.
$40 \times 10^{-6}$	High overtones strong.
$20 \times 10^{-6}$	Quality good.

TABLE VI.

ELECTRODES, CARBON, PLATINUM.—*Magnification, 700 diameters.*

Excursion.	Character of Sound.
$200 \times 10^{-6}$	Rough, but pitch discernible.
$80 \times 10^{-6}$	Rough, pitch distinct.
$30 \times 10^{-6}$	Smooth, with high overtones.
$30 \times 10^{-6}$	"
$20 \times 10^{-6}$	Quality good; some high overtones.
$10 \times 10^{-6}$	Good quality.
$25 \times 10^{-6}$	Smooth, with high overtones.
$30 \times 10^{-6}$ to $40 \times 10^{-6}$	High overtones prominent.
$80 \times 10^{-6}$	Harsh and rough.

TABLE VII.

ELECTRODES, CARBON, PLATINUM.—*Magnification, 940 diameters.*

Excursion.	Character of Sound.
$1,000 \times 10^{-6}$ to $800 \times 10^{-6}$	Scratchy, with breaks.
$100 \times 10^{-6}$	Rough, with high overtones.
$80 \times 10^{-6}$	Wheezy, with high overtones.
$40 \times 10^{-6}$	Smooth, but with high overtones.
$30 \times 10^{-6}$	"
$60 \times 10^{-6}$	Rough, with high overtones.
$50 \times 10^{-6}$	Harsh, with high overtones.
$40 \times 10^{-6}$	Smoother.
$30 \times 10^{-6}$	Smoother, with high overtones.
$20 \times 10^{-6}$ to $30 \times 10^{-6}$	Good quality, high overtones present.
$20 \times 10^{-6}$	Good quality.

TABLE VIII.

ELECTRODES, CARBON, PLATINUM.—*Magnification, 940 diameters.*

Excursion.	Character of Sound.
$1,000 \times 10^{-6}$	Harsh and screamy.
$2,000 \times 10^{-6}$	"
$1,000 \times 10^{-6}$	High overtones heard; no distinct pitch transmitted.
$400 \times 10^{-6}$	High strident overtones present.
$100 \times 10^{-6}$	High overtones still present.
$60 \times 10^{-6}$	Sound wheezy.
$30 \times 10^{-6}$	Sound smooth.
$20 \times 10^{-6}$ to $10 \times 10^{-6}$	Quality good.

The differences in the effects obtained with a microphone in which both electrodes are of carbon, as compared with one in which one of the electrodes is of platinum, are well known to every one who has considered the subject. While with the latter it is more easy to produce an actual break of contact between the electrodes than with the former when the sound is increased, on the other hand the quality is much more satisfactorily reproduced, and does not so rapidly disappear on increasing the loudness. These differences were clearly noticed in the observations. Thus for slight excursions of the hammer electrode the quality of the sound with two carbon electrodes was found to be less satisfactory than when the hammer was of platinum, although in the latter case the point of actual breaking of circuit and sparking was usually reached with a less excursion than in the former one. Evidence of these differences appears in the tables just given, and also in those which follow.

It must be observed that while the figures given in the tables show what is the maximum amplitude of vibration of the electrodes consistent with the transmission of quality, they entirely fail to indicate the excessive minuteness of the least excursions which are capable of this result. How minute these sometimes are may be inferred from the following observation.

With a microphone having a somewhat heavy anvil electrode, the organ pipe was gradually moved away from the diaphragm, and the diminishing range of motion of the electrodes noted in the usual manner. When the pipe was at a distance of three inches the motion of the electrodes was too slight to be visible, although this could have been seen readily with the low magnifying power employed if it had been as great as  $\frac{1}{20000}$  in. The pipe, still blown with the same loudness, was then carried farther and farther away. At a distance of 36 feet, which was the most distant point from the microphone in the room, the sound of the pipe was still distinctly though faintly audible at the receiver placed in circuit with the microphone, and in a distant apartment.

The results shown in the preceding tables give an idea of the phenomena observable with a microphone of the structure employed. Inasmuch as the primary object of the measurements was to obtain some idea of the actual value of the excursion of the electrode, the mass and normal pressure of the electrodes were not particularly considered, except that they were so adjusted as to give good transmission with moderate loudness of the sound actuating the microphone. But it would of course be expected that the numerical value of the relative excursion of the electrodes corresponding to any given character of sound would vary with the mass of the anvil electrode and with the normal pressure between the electrodes. Two separate sets of observations were made to observe the effects of such variations by Messrs. Jones and Dame. The latter series was somewhat more complete than the former, besides being carried on with better instrumental appliances, and the results hereafter given are taken chiefly from it.

In all experiments of the nature of those under consideration, it is very difficult to get any fixed standard of quality to which to refer such results as the present. Different observers differ to a certain extent in their estimate of the excellence of the quality reproduced. But the point at which the distinctive quality of the transmitted sound disappears is quite well marked, and a very slightly increased vibration of the hammer electrode causes great harshness to result. For this reason, the name "critical point," originally suggested by Mr. Jones, has been given to this limit, and the excursion corresponding to it has been particularly noted, in tests of the varying effects of mass and pressure.

The transmitter used had its anvil electrode suspended like a pendulum, as before. In order to vary the mass without varying the normal pressure, a horizontal wire was suspended beneath the anvil electrode and rigidly attached to it. The middle point of the wire was vertically beneath the point of suspension of the electrode. The masses added consisted of small copper washers weighing 1.1 grams each. By adding two of these whenever the mass was to be increased, and placing one on each side of the middle point of the horizontal wire, the mass of the electrode was increased, while the normal pressure remained substantially constant. In the experiments whose results are contained in Tables IX. to XIII. the normal pressure was exceedingly small, the electrodes always being kept in very light contact. This condition of things was easily secured by a slight adjustment of the position of the washers. A magnification of 280 diameters was usually employed.

The following results were obtained by the mode of procedure just described.

14.25	37 × 10 <sup>-6</sup>
18.65	37 × 10 <sup>-6</sup>
20.85	37 × 10 <sup>-6</sup>

An inspection of Tables IX. to XIII. shows that the value of the excursion of the hammer electrode corresponding to the "critical point," and presumably, therefore, the excursion corresponding to any given degree of excellence in the reproduction of quality, at first rises very rapidly as the mass of the anvil electrode is increased, but soon reaches a maximum value, which is not altered by further increase of mass. The rise appears to be less rapid when both electrodes are of carbon, than when one or both of them are of platinum, as may be seen by a comparison of the various tables, or, better still, by plotting the results so as to exhibit them graphically by curves. Also, when both electrodes are of carbon or both of platinum, the maximum and permanent excursion at the critical point is considerably less than when the hammer electrode is of platinum and the anvil of carbon, a fact which goes to explain the well-known excellence of a microphone employing these last materials. Further experiment is desirable, however, before fully accepting this explanation. Furthermore, variations in the surface and shape of the electrodes are likely to modify these values to a certain extent. Thus the carbon electrodes used by Mr. Jones gave the results shown in Tables XIV. and XV. The arrangement of the electrodes was as already described, except that the anvil was slightly inclined, and in the second series a weight of bent wire was added to increase the normal pressure by a small amount.

TABLE XIV.

25.7	60 × 10 <sup>-6</sup>

TABLE XV.

ELECTRODES, CARBON, CARBON.

Mass in Grams.	Excursion of Hammer at Critical Point.
2.9	29 × 10 <sup>-6</sup>
5.3	30 × 10 <sup>-6</sup>
7.7	40 × 10 <sup>-6</sup>
10.1	55 × 10 <sup>-6</sup>
12.5	60 × 10 <sup>-6</sup>
14.9	60 × 10 <sup>-6</sup>
17.3	60 × 10 <sup>-6</sup>

In connection with the various preceding tables the following results obtained by Mr. Jones will be of interest.

TABLE XVI.

ELECTRODES, CARBON, PLATINUM.

Series.	Magnification.	Excursion for Good Quality.	Excursion at Critical Point.	Excursion for Breaking.
1	400	16 × 10 <sup>-6</sup>	60 × 10 <sup>-6</sup>	80 × 10 <sup>-6</sup>
2	400	20 × 10 <sup>-6</sup>	30-40 × 10 <sup>-6</sup>	60 × 10 <sup>-6</sup>
3	400	30 × 10 <sup>-6</sup>	50 × 10 <sup>-6</sup>	80 × 10 <sup>-6</sup>
4	350	30 × 10 <sup>-6</sup>	60 × 10 <sup>-6</sup>	80 × 10 <sup>-6</sup>
5	700	40 × 10 <sup>-6</sup>	60 × 10 <sup>-6</sup>	80 × 10 <sup>-6</sup>
6	1000	30 × 10 <sup>-6</sup>	70 × 10 <sup>-6</sup>	80 × 10 <sup>-6</sup>

In Series 2 the normal pressure was slightly less than in the others. The excessively high value of 40 × 10<sup>-6</sup>

at which in Series 5 good quality still persisted, is the highest that has been observed. The hammer electrode had been brought to a sharp point just previously.

I have observed, among the four persons who have employed the method under consideration, that each one has apparently his own standard of what constitutes good quality, and usually adheres quite closely to this in different experiments. The observer last cited generally gave somewhat larger values to the excursion for a given degree of excellence of transmission than I noted in my own observations, apparently from this cause.

A further series of measurements was made in order to ascertain what effect was produced by a variation in the normal pressure between the electrodes.

In order to do this, a wire was caused to project backward from the anvil electrode, and small weights were hung upon the end of it. The pendulum electrode with this projecting wire constituted a bent lever whose arms were easily measured, thus enabling the normal pressure due to a given weight to be calculated. It was thus obtained very easily, although the method is subject to the objection that there is a certain variation of the mass of the anvil electrode simultaneously with the variation in pressure. The use of a delicate spring instead of the weight would be preferable, but I have not yet found time to carry through observations by this method. The results reached are shown in Tables XVII. to XIX.

TABLE XVII.

ELECTRODES, PLATINUM, PLATINUM.	
Normal Pressure in Grams.	Excursion of Hammer at Critical Point.
0.34	$8 \times 10^{-6}$

2.150	$25 \times 10^{-6}$
0.272	$8 \times 10^{-6}$
0.616	$25 \times 10^{-6}$
0.960	$37 \times 10^{-6}$
1.304	$37 \times 10^{-6}$
1.648	$37 \times 10^{-6}$
1.990	$37 \times 10^{-6}$

TABLE XIX.

ELECTRODES, CARBON, PLATINUM.			
Normal Pressure in Grams.	Excursion of Hammer at Critical Point.	Normal Pressure in Grams.	Excursion of Hammer at Critical Point.
0.184	$8 \times 10^{-6}$	0.184	$8 \times 10^{-6}$
0.288	$12 \times 10^{-6}$	0.288	$12 \times 10^{-6}$
0.432	$12 \times 10^{-6}$	0.632	$12 \times 10^{-6}$
0.632	$12 \times 10^{-6}$	0.990	$12 \times 10^{-6}$
0.990	$12 \times 10^{-6}$		
1.288	$12 \times 10^{-6}$	0.180	$8 \times 10^{-6}$
1.654	Anvil vibrating.	0.395	$12 \times 10^{-6}$
		0.620	$12 \times 10^{-6}$
0.104	$>8 \times 10^{-6}$	0.644	$12 \times 10^{-6}$
0.132	$>8 \times 10^{-6}$	0.149	$8 \times 10^{-6}$
0.153	$8 \times 10^{-6}$		

It appears from these results, that the value of the excursion corresponding to the critical point rises with increase of normal pressure, soon attaining a maximum and constant value. The pressure at which this maximum value was reached was greatest when both electrodes were of platinum, and least when the hammer electrode was of platinum and the anvil of carbon. When both electrodes were of carbon, the value lay between these two extremes. The unexpected result was also reached that the value of the maximum excursion was much greater when both electrodes were of platinum than when both were of carbon. It was least when the hammer was of platinum and the anvil of carbon.

A series of observations was also made upon the microphone of the Blake transmitter. These presented considerable difficulty on account of the construction of the parts of that instrument, and only a low magnifi-

cation could be used. Three sets of measurements were taken, the first with a very light normal pressure, the second with the ordinary pressure, and the third with a very heavy pressure. With this microphone in its proper condition, both electrodes moved. It was therefore necessary to subtract the excursion of the anvil electrode from that of the hammer, in order to obtain their relative motion. The results reached are given in Table XX. The total excursion of the hammer electrode, and its motion relative to the anvil, are given as nearly as they could be measured.

TABLE XX.

BLAKE TRANSMITTER.—ELECTRODES, CARBON, PLATINUM.

A. Light Normal Pressure.		
Total Excursion.	Relative Excursion.	Character of Sound.
	$<25 \times 10^{-6}$	Good quality, very faint.
$50 \times 10^{-6}$	$25 \times 10^{-6}$	" " clear.
$100 \times 10^{-6}$	$50 \times 10^{-6}$	Overtones strong.
B. Medium Normal Pressure.		
	$<25 \times 10^{-6}$	Good quality, very faint.
$75 \times 10^{-6}$	$25 \times 10^{-6}$	" " clear.
$100 \times 10^{-6}$	$50 \times 10^{-6}$	Overtones strong.
C. Heavy Normal Pressure.		
	$<25 \times 10^{-6}$	Good quality, very faint.
$100 \times 10^{-6}$	$25 \times 10^{-6}$	" " clear.
$150 \times 10^{-6}$	$50 \times 10^{-6}$	Overtones strong.

These results, although of only approximate exactness, are interesting, as they show one cause of the excellence of the Blake transmitter in practice, in that the mode of support of the electrodes allows of very considerable variations in the absolute motions of both of them without material change in their relative motions.

Rogers Laboratory of Physics,  
March, 1890.

ELECTRIC LIGHT FATALITIES.

ON September 30th last an inquest was held to enquire into the cause of the death of August Kopp, who was killed while at work on an electric light pole at the corner of Thirty-fifth Street and Broadway, in New York, on the night of the fifteenth of the month, and whose untimely end has already been noticed in our columns. The coroner's jury, composed principally of electrical men, brought in a verdict to the effect that Kopp would not have lost his life had he exercised proper care (*i.e.*, had he been wearing at the time the rubber gloves provided by the company), and further, that "while said August Kopp did not exercise proper care, it has appeared in evidence that the defective insulation which existed at the various arc lamps was a necessary factor in causing his death; and that the existence of such defective insulation was countenanced by the Board of Electrical Control. It is the opinion of this jury that the operation of high-tension electric circuits in such condition is a dangerous practice."

For a proper understanding of this verdict, says the New York *India-rubber World*, it is necessary to review the evidence given at the inquest, by which the exact manner in which Kopp met his death and the various contributing causes were made clear. It appears that Kopp, who was a patrolman in the employ of the United States Illuminating Company, was inspecting the working of the lamps in a certain district on the night in question, and observing that the lamp at Thirty-fifth Street and Broadway was extinguished, he climbed the pole to remove the cause of trouble, although he had left his rubber gloves at the Central station. Kopp, therefore, did not "exercise proper care," and directly violated the rules of the company which provide that all employes shall wear rubber gloves when working on live circuits. It is a matter of history that he paid the penalty of his excess of zeal with his life, but exactly how this came about has not

been correctly stated in any published report of the accident.

It appears from the evidence that the circuit was grounded on the lamp frame through a defective insulator and Kopp's idea was to remove the ground from the circuit by cutting out the lamp. He effected this by baring a small portion of the insulated wires by which the lamp was connected to the cables and joining them across by means of a "jumper"—a short, thick piece of wire heavily insulated and provided with a clamp at either end for making the connections. Having thus cut out the lamp, he proceeded to disconnect the wires from the lamp terminals, and endeavoured to twist them together in order that he might remove the jumper. In making the attempt, he touched one of the bare ends and thereby received the shock that resulted in his death.

It would appear to most persons that, having fixed the "jumper" properly and so completed the circuit, Kopp ought to have been able to handle the free ends without receiving any hurt, as they then only represented one side of the circuit. His death having been produced in this way shows that the circuit must have been grounded at some other point, or at least that the total insulation of the circuit was so low that it practically amounted to a ground; Kopp, clinging to the iron pole and lamp support, made a second ground, and he naturally received a powerful shock.

The circuit consisted of about  $4\frac{1}{2}$  miles of underground cable,  $1\frac{1}{2}$  miles of overhead wire and 48 arc lamps, and according to the evidence of the self-satisfied gentleman who poses as expert to the Board of Electrical Control, the insulation of the entire circuit, measured in *fine weather*, was about 1.6 megohms. This result was obtained some days before the accident and some days after, but no test was made on the day of the accident or on the day following. Wet weather prevailed about that time, and it had never occurred either to the expert or to the superintendent of the company to have a test made in wet weather, and the latter official could only guess at the probable insulation of the circuit under such conditions, placing it at about half a megohm. This was a very liberal estimate, about a fiftieth part of that figure would probably be nearer the mark. The point is that the company did not know and the "expert" to the Board did not know how low the insulation fell, or, in other words, whether the circuit was safe or dangerous in wet weather, and apparently they did not care to know; they could only say that under the best conditions the insulation of the circuit was fairly good. The experience of lineman Kopp showed that in wet weather to touch one side only of the circuit meant death, and the company owe it to their good luck that the man had infringed their rules in not carrying his rubber gloves, as even though he had had them the wire might have touched some other part of his body, say his neck or face, in which case he would have been killed just the same.

The evidence given on behalf of the company shed some light on a lamentable method, or rather want of method, in testing circuits and keeping records of tests made. It is with some surprise that we learn of an important company, like the one in question clinging to the antiquated magneto bell test—a test which means nothing at all, as the witness for the company could not even say what resistance the bell would ring through, the deduction being that it would only show whether the circuit was dead grounded or not. The insulation might fall dangerously low, but the magneto would give no sign.

The main point to be borne in mind in connection with this peculiar case is that Kopp was killed because the insulation of the circuit was so low as practically to amount to a "ground." The witness for the company accounted for this low insulation by crediting it to the accumulation of leakage from the arc lamps, the frames of which form part of the circuit. This explanation probably accounts for a great deal of the leakage, and the rest would no doubt be made up among the overhead wires, and poorly insulated connections between lamps and cables.

The fact remains, however, that the insulation of such a circuit falls dangerously low in wet weather, and we fully concur in the verdict of the jury characterising the operation of high-tension circuits in such condition as a dangerous practice. It remains for the electric light companies to find the remedy, and it would clearly seem to be the duty of the Board of Electrical Control to insist upon some remedy being applied. If the present construction of arc lamps is such that they afford escapes for the current in wet weather, it ought to be no very difficult matter to improve the construction so as to eliminate this dangerous defect. A vast amount of work has been done in the production of efficient arc lamps, surely our industrious inventors might now turn their attention to the design of one that shall be safe.

We sympathise with the electric light companies to a certain extent for the persecution they underwent last winter, but at the same time we have an idea that they are rather inclined to carry things with a high hand where they have the chance; now that it has been clearly shown that the first element to be considered in the operation of high-tension currents, namely, insulation, is disregarded to the extent of rendering the operation of their circuits a "dangerous practice," we think that the sooner they are compelled to adopt improvements in their methods of construction the better it will be for all parties concerned.

## PRACTICAL PROBLEMS.

OUR readers, says the editor of *L'Electricien*, often ask questions of general interest demanding a reply that would exceed the limits of space that we can devote to them in the correspondence column. We will in future answer them under the heading "Practical Problems," which we now introduce. We shall number these problems, as we number the items of useful information, in order to facilitate reference.

I. Provisional employment of accumulators in a lighting of 110 volts.

A consumer supplied normally by a machine with a constant potential of 110 volts wishes to keep four or five lamps lighted for some hours in the daytime, or when the machine is stopped for repairs or cleaning.

It is evident, in this particular case, that he must have recourse to accumulators; but the solution that suggests itself, *à priori*, and which consists of establishing a series of 55 accumulators in derivation on the dynamo, is far from being either the most economical or the most simple method.

In short, these 55 accumulators entail at the outset an expenditure which cannot be less than 800 francs, as the smallest industrial type of accumulator costs at least 15 francs.

We should prefer to substitute for the four or five lamps that are to work while the motor is stopped, double the number of lamps working at 25 or 30 volts, for instance, requiring only from 13 to 15 accumulators for their maintenance. The four or five lamps working at 75 or 80 volts are connected in derivation from one to another, but in series with the battery of accumulators, and in derivation on the terminals of the dynamo, which then charges the battery at the same time as it supplies the lamps connected in series with the accumulators.

At the moment of stoppage, a simple commutator cuts off the communication between the accumulators and the machine and the lamps of 75 volts, and places the lamps of 30 volts in derivation on the accumulators. We thus realise a considerable saving on the cost of the accumulators, and we are sure of charging them with a current that is very constant, which is favourable to their preservation. The doubling of the lamps may be avoided by installing lamps of 50 volts which, during the charge, would be connected in series with the accumulators, and in derivation on the terminals of the dynamo. During the discharge, the accumulators and

the lamps would be separated from the dynamo, and the accumulators would supply the same lamps of 50 volts. By this second method, 27 or 28 accumulators would be required instead of 55; but the first plan is the more advantageous, for, taking into consideration the high price of the accumulators and their depreciation, it is still more economical to double the number of lamps than to double the number of accumulators.

If the attendant should happen to forget to use the commutator at the moment when the dynamo stopped, the accumulators would only be discharged very slowly over the resistance represented by the lamps of 75 volts introduced into the circuit charged. It is, moreover, easy to arrange that an automatic disconnecter should effect the commutation at the moment of the stoppage of the dynamo, for the current supplied by the accumulators being of an opposite sign to that supplied by the dynamo during the charge, it must pass through zero in order to change its sign, and thus the disconnecter cannot fail to act at the moment required.

We will suppose that lamps of 50 watts (16 candles) are required, each requiring 25 volts and about 2 ampères. The output will be 15 ampères. We shall only require to use 13 accumulators at 25 francs each, or 325 francs worth of accumulators instead of 800, in order to supply this special service. These accumulators, containing 100 available ampère hours, will ensure the working of the five lamps for 10 hours, which is more than sufficient in this particular case.

The method we have described of lessening the number of accumulators required in an installation with a potential of 110 volts may be applied in all cases in which these accumulators are only required to supply a limited number of lamps, late at night, for instance.

### SOME OF THE ENGINEERING PROBLEMS CONNECTED WITH THE RE-ESTABLISH- MENT OF THE WESTERN UNION TELE- GRAPH COMPANY, AFTER ITS RECENT FIRE IN NEW YORK CITY.\*

[By A. C. ROBBINS.

ON the morning of the 18th of July last, occurred the most disastrous fire in the history of the electric telegraph. The General Operating Department of the Western Union Telegraph Company, at New York, was completely destroyed. The general operating room occupied the entire seventh floor of the Western Union building, with a frontage on Broadway of 75 feet, and on Dey Street of 150 feet, and furnishes employment to upwards of one thousand people, operators, clerks and messengers. The height of the room was about 21 feet. A gallery extended across the Broadway end of the room, and was occupied by the Commercial News Bureau.

The room contained a main line switch having a capacity of about 700 wires; a city line switch with about 250 wires; a loop switch of 200 loops; 40 sets of quadruplex instruments; 40 sets of duplex instruments; about 700 simplex instruments; the pneumatic tube system; 3 sets of the Hughes-Phelps printing telegraph apparatus; a rapid transit distributing system; and offices of the management and staff.

The battery room was located on the sixth floor, and contained about 20,000 cells, principally of the zinc-copper, gravity form. The coat and toilet rooms were also on this floor.

The eighth floor was occupied by the Associated Press operating department, and the Western Union book-keeping department and the *employés'* lunch room.

The ninth floor contained the kitchen and lodging rooms of the lunch room *employés*. The tenth floor was used as store rooms for records, and other miscellaneous matter.

The wires entered the building at the cellar, and were 2,000 in number, conveyed to the operating room in cables containing from 50 to 100 wires each, through flues in the central partition wall of the building.

How the fire originated is something of a mystery, and probably will ever remain so. It was discovered by various people on the sixth and seventh floors simultaneously at about 7 o'clock, and spread with such rapidity that several who tarried a few moments in vain endeavour to extinguish it, found the stairways a seething mass of flame, and their only means of escape to be through the windows, from which they were in various ways rescued by gallant firemen, happily without loss of life or accident; as was the case with some half dozen *employés* who were rescued from the roof by the life-saving corps of the fire department.

While the engines were yet playing upon the building, operators were detailed to Jersey City, Brooklyn, Weehawken, Hoboken, Harlem, and all possible available suburban offices in all directions, there to tap the wires, and handle the vast business as best they could.

Almost before the fire was entirely extinguished a part of the engineering staff repaired to the former operating room of the defunct Baltimore and Ohio Telegraph Company, on the fifth floor of No. 415, Broadway, where, with only a room destitute of all furniture, an electric light dynamo in the cellar, and a permit from the authorities to string a few temporary aerial wires, they proceeded to open up communication with the outside world.

Cables were strung to, and connected with, the trunk line cables on the Sixth Avenue Elevated Railway structure, the dynamo in the cellar was put in operation, and at seven o'clock in the evening, after seven hours' labour, they were working their first wires. By Saturday morning they were working 20 wires; and on Saturday evening electric lights, furnished with current from the dynamo in the cellar, replaced the candles and lanterns of the previous night. On Sunday morning a second dynamo for furnishing current of opposite polarity to that of the first one was in operation, and 12 duplex systems were started. Monday morning found this energetic party operating 15 duplex and 25 simplex circuits to the north, east and south.

The fire occurred on the regular weekly pay-day of the *employés*, and the systematic and business-like methods of this company is finely illustrated in the fact that every *employé* who presented his voucher to the cashier on that day received his salary. One *employé* humorously remarked that while the engines were pouring water into one window he received his money from out another.

The scene inside the building, after the fire, beggars description. It was enough to discourage the stoutest heart. Everything burnable above the fifth floor was entirely consumed. In the operating room, the largest piece of combustible material left was the leg of a table.

The once magnificent switchboard was reduced to a mass of melted brass, and twisted beams, and to trace the identity of a single wire from out the tangled mass would be as difficult as tracing a thread in the broken web of a spider.

Water flowed from the building in rivers, and for days afterward dripped from the ceilings of every floor. This dripping was the source of great annoyance in the work of reconstruction, and in many instances, during the first few days, instruments and wires had to be covered with tarpaulin to protect them from the water.

On the morning succeeding the fire new life was inaugurated amidst the ruins. The fifth and a part of the fourth floors were to be converted temporarily to the uses of the operating department.

The occupants of these rooms were busy removing to other quarters; an army of workmen were engaged in erecting switches, building tables, setting up instruments, and running wires.

\* Paper read before the Electrical Department of the Brooklyn Institute, October 10th, 1890.

The conduit from the cellar was opened in the hall on the fourth floor, and the work of testing out and identifying each one of the 2,000 wires therein was commenced. The pneumatic tubes were opened up in, and business with their terminals conducted from, the cellar.

Day and night the work progressed, until, one by one, as fast as wires were provided, the entire force was brought back. On the following Saturday, eight days after the fire, nearly all of the wrecked wires had been re-connected in working order at the general operating department, and the temporary quarters at 415, Broadway, were abandoned.

Gradually the business resumed its former and well organised routine, until to-day, as for several weeks past, with rude pine benches for desks, and wires strung promiscuously around the ceilings, an unusual delay to a *single* message, and the cause therefor, is instantly known to the management.

One of the worst difficulties encountered in this re-establishment was a lack of proper apparatus, and at times the engineering staff were severely taxed in substituting for apparatus not in stock, and which was needed immediately; for instance, the dynamo duplex and quadruplex systems require pole reversing transmitters different from the ordinary, in that they require only two points of contact in place of four, where a battery is used.

The dynamo quadruplex system also requires resistances of 600, 900 and 1,200 ohms respectively, in proportioning its currents, and it also requires a set of battery and ground switches of peculiar construction.

Of this apparatus, and much more, only samples are kept in stock, and considerable time is necessary to construct when required. In substituting for the pole reversing transmitters, the battery style (of which, fortunately, there was a good supply) was used by the insertion of ivory insulation on two of its contact points. For the quadruplex proportional resistances, incandescent lamps were used until the proper resistance coils could be obtained. While the lamps, as a makeshift, answered fairly well, I cannot say that I consider them a decided success, as they are too sensitive to changes of temperature. The proper equilibrium of the apparatus at the distant station, to a very considerable extent, depends upon the joint resistance of the 900 and 1,200 ohm resistances; equalising that of the independent 600 ohm resistance; and, again, the outgoing current is regulated in proportion as is the 900 to the 1,200 ohm resistance, so that a quadruplex circuit working nicely for a part of the day, is liable to become unsteady, or variable later on by a change in the wind, or draughts of air from an open window, which may cause one set of resistance to vary considerably more than the others. Constant watching, however, partly overcame this difficulty. For 9 point combination dynamo and ground switches, 3 point switches were connected in substitution.

Another difficulty experienced was the want of battery room. No room was available for this purpose, except some shelves in the halls, and boxes under the desks. This was overcome by using the Edison-Lalande caustic soda battery, which, while of low pressure, furnishes quantity sufficient for from 8 to 10 circuits from one battery.

There are 5 local circuits on each set of quadruplex instruments; these circuits ordinarily require 10 cells of gravity battery; 4 cells of the caustic soda battery has been found ample to work the local circuits of two sets of quadruplex, a saving of 16 cells, or 80 per cent. in battery room. The same percentage was secured in saving of battery room for the local batteries of the multiplex city loops, several loops being supplied from one battery.

The 20,000 cells of battery used previous to the fire have been replaced by 1,750 cells; and, in a few weeks, perhaps days, not a single cell of chemical battery will be used for telegraph purposes in the general operating department.

For several years past the dynamo has provided current for the main circuits from New York. A poten-

tial of 70 volts, regulated by a system of joint resistance, multiple supply, has been applied for supplying the loop locals. For intermediate batteries special apparatus is required for each battery. A one-eighth horsepower motor is by current from the building incandescent lamp circuit, run at a speed of about 2,200 revolutions per minute. This motor in its turn operates a generator of equal size and at about the same rate of speed, from which is obtained a current potential of about 100 volts—sufficient for all intermediate battery purposes. The saving in room is 40 square feet for each intermediate battery. About 50 intermediate batteries were formerly used, but the number will probably be reduced somewhat.

Another question of space was presented when incandescent lamp room was considered. Each battery lead before reaching its wires has a resistance inserted in form of from one to four incandescent lamps for the prevention of damage in cases of accidental short-circuiting. 5,000 of these lamps are necessary for use on the main line switches, and as each lamp requires a space of 3 square inches, or a total of 104 square feet, the problem was an important one.

This was happily solved by placing the lamps on a framework over the switch. In so doing two results are obtained, viz.: Space otherwise useless is utilised; and, secondly, yet of still greater importance, the wire chief is enabled, by watching his lamps to note grounds and crosses on his wires, and by prompt action from such observation prevent destruction by overheating of the instruments in circuit. For the multiplex currents, spaces on the framework of the doors and windows have been utilised, and the lamps thereon serve as monitors for those in charge of the apparatus.

Previous to this arrangement, the burning out of magnets by accidents to heavily charged circuits was a frequent occurrence. Since this improvement, I have yet to hear of the destruction of a single coil in this manner.

The building stood the heat wonderfully well; heat which caused the granite trimmings of the doors and windows to flake and crumble, and glass to melt, had no effect whatever upon the massive walls.

The operating room which, when first occupied some 17 years ago, was generally supposed to be adequate to the requirements of the department for all time to come, has for years been entirely too small for the rapidly increasing business.

Particularly during the past five years have these quarters become crowded, and the stern necessity of utilising every inch of available space been forced upon the management.

Just previous to the fire a prominent official of the department remarked that he did not see how they could work through the coming busy summer season without more room, and that to do so a year hence would certainly be an impossibility. This is only one of many indications of the rapid growth of the telegraph business in recent years. With this experience, it has been decided to rebuild the structure from the fifth floor up, and to extend the building 25 feet on Dey Street; and it is confidently predicted that when completed it will be the finest and most complete telegraph office in the world.

The remodelled building will be nine storeys high, and the old mansard will be replaced by a flat roof. The sixth floor will be used for offices for various departments; the seventh and eighth floors for operating rooms, and the ninth floor will be occupied by wardrobe and lunch rooms, kitchen, &c.

The operating rooms on the seventh and eighth floors will each have a frontage on Broadway of 75 feet, and on Dey Street of 175 feet—considerably more than double the space occupied before the fire, and will be furnished with every facility that can be procured to secure perfection of operation. There will be used twelve dynamos in series of four each for the main line batteries, two only being in use at any one time, and the third series being kept in reserve in case of accident to either of the others. Two dynamos of low voltage will furnish the current for instrument local

circuits, one being used and the other held in reserve. Two dynamos will be devoted to supplying current for city multiplex loop, local circuits, one of them as a reserve; and as many sets of the one-eighth horse-power motors and generators will be used as there may be intermediate batteries required. The chemical battery will have no place in this model telegraph equipment, its day of usefulness having passed.

To the telegraph engineer it is a pleasing one. It marks an advance of the telegraph, in keeping with the progress of electrical science up to the present time, and we can feel assured that the results will be such as to induce the management to apply the improvements to all the principal offices of the company in the near future.

There is great need of improvements in insulating material. An insulation for wires is needed that will be cheap, light, flexible, and durable; one that dampness will not decay, nor the heat of an electric arc dissolve or burn. A fire extinguishing liquid is also to be desired which will be a non-conductor of electricity. When these have been obtained, and not until then, can the large telegraph offices be absolutely assured of protection from fire.

Please consider this matter. The one who succeeds in obtaining these results will, I am sure, be richly rewarded for his trouble. Nearly all the *employés* lost personal property in the fire, of greater or less value. Some of the losses were memoranda of experiments never to be repeated, or the gift of some departed friend, and can never be replaced. To some of the *employés* their losses were, to them, a much more serious matter than was to the company its more formidable calamity; yet from these *employés* are heard no complaints or lamentations; and, with sad regrets for their misfortune, all turned with eager hands to lend their aid to the restoration of public service.

This disaster has demonstrated that there is to-day between the Western Union Telegraph Company, and its *employés* in New York City, a combination of capital, labour, and harmony. Capital for dividend on its investment; labour for the love of science, and advancement of its chosen profession, and both harmonising in successful endeavour to make the now largest telegraph office the most perfect one in the world.

### A SUGGESTION.

(COMMUNICATED.)

AT present there are many English electrical firms who would be disposed to undertake an export trade, whilst others who have already established foreign connections are desirous of extending their sphere of operations in other countries. The difficulties to be overcome, however, in order to attain these objects are so great that some firms have given up the idea of opening up or cultivating an export trade. The first question which arises in the mind is, how are foreign business transactions to be effected? There appear to be only two methods which can be adopted. The first is the formation of a branch house. It would, of course, necessitate the expenditure of too much money to establish branch offices in different countries, although two or three electrical firms have already taken this step by founding branch offices abroad. Still, to the majority this would be impossible, and the idea may therefore be left out of consideration. The alternative is the appointment of *bonâ fide* representatives capable of efficiently carrying out work according to instructions. But the difficulty to be surmounted is to ascertain the good faith of foreign importers or representatives.

The two electrical directories are excellent as far as they treat the electrical industries, but they do not give all the information which an exporter would desire to know, and the choice of an agent from either might lead to pecuniary loss. What is, therefore, required is

an electrical trades handbook for the export trade. It should give in numerical order the names and addresses of only financially sound English and foreign export firms, together with a list of the specialities sent and received abroad, of the goods made by English export firms, details of electrical apparatus imported into foreign countries, their coinage, weights and measures, customs' tariffs, cost and means of transport, the names of responsible agents, lawyers, banks, importers at the principal ports, practical hints as to the means of trading, and last, but not least, a "black list" of those firms with whom it is undesirable to transact business without pre-payment *in cash*. A book of this kind would show to the exporter what to arrange and what to avoid. This want has just been filled in Germany for almost all trades, by Messrs. W. J. Schmidt and Gelbrecht, of Berlin, N., who have published a volume entitled, *Export-Hand-Adressbuch von Deutschland*. The list of export firms alone numbers over 4,200, the electrical industry being but briefly referred to. The black list is remarkable, and one of the many peculiar cases is worth mentioning. A Vienna boot manufacturing firm sent to an agent in London a case of boots as samples, but they were not returned, notwithstanding the fact that all of them were for the *right foot*!

### THE FLORENCE ELECTRIC TRAMWAY.

SINCE the Note appeared in our last issue regarding the electric tramcar accident in Florence, a copy of our Italian contemporary, *L'Elettricità*, containing a description of the tramway, has come to hand. The Sprague system, as worked in the Italian town, does appear to be, as the correspondent of the *Standard* pointed out, "a complicated arrangement of overhead wires."

The generating station is situated at S. Gervasio, in Fiesolo, and contains three large tubular boilers made by Tosi Brothers, of Legnano. These boilers supply steam to three compound engines furnished by the Oerlikon Engineering Works. Each engine runs at 245 revolutions and is of 100 H.P. The engines drive three Sprague dynamos at 900 revolutions, the capacity of each being 55,000 watts. All the electrical plant has been despatched from the Schenectady works of the Sprague Motor and Railway Company. The tramway is 5 kilometres in length, and in addition to the many curves, the difference in level between the Piazza S. Marco in Florence, and the Piazza del Duomo in Fiesolo, is about 270 yards. One pole of each dynamo is connected with an insulated main copper cable which is carried at the side of the tramway, whilst the other pole is jointed to a second or binary wire, which forms the return. The main cable is attached by means of insulators to vertical standards arranged laterally along the route at intervals of from 32 to 43 yards. From this cable branches are taken off to a secondary conductor termed the service wire, which consists of silicon bronze 5 mm. in diameter. The latter is placed slightly above the return wire, and is partly supported by brackets projecting from the standards and partly by means of wires arranged transversely. The standards erected inside Florence consist of light iron posts placed at the side of the footpaths, whilst outside the town they are wooden masts, all being about 20 feet high. The current is collected from the service wire by means of a trolley supported by an arm from the roof of the car, and passes down to the motors. Each car has arranged under its body two Sprague motors of 15 H.P. each, each motor driving independently one of the axles by means of gearing. A switch for increasing or diminishing the speed is placed at each end of the car. The number of cars in service is 12, each having a seating capacity for 24 passengers. The cars are lighted inside by five incandescent lamps, whilst externally there are two lamps which serve as head lights.

# RECENT RESEARCHES ON THE ELECTRICAL CONDUCTIVITY OF CERTAIN LIQUIDS.

CONDUCTORS of electricity may be regarded from two points of view. They may be considered as endowed with a greater or less facility for allowing electricity to pass through them, and, again, they may be considered, when placed in a circuit, as offering a greater or less resistance to the passage of an electric current. Each of these methods of regarding conductors is, in algebraical language, the *inverse* of the other.

We need not here enter into the relative merits and demerits of the various plans which are generally used for measuring conductivity and resistance. They are familiar to every student of electricity. But in the investigation of these properties, in so far as they are exhibited by certain particular substances, it is often necessary to modify the details, if not the principle, of any experimental method which may be resorted to, and these will be alluded to in due course.

To the early observers, the metals presented themselves as the most obvious conductors of electricity, and it was some time before it was definitely recognised that many other substances, supposed to be indifferent in their action, possessed the property of conductivity, although in varying degrees. Matthiessen's work on the conductivity of metals at zero Centigrade is still regarded as standard, but other physicists have obtained very conflicting results. This has mainly arisen from the character of the specimens examined; they have rarely been uniformly pure, and have often possessed a different molecular character.

The influence of temperature upon the conductivity of substances is affected by the physical condition of those substances. In the case of the metals, it has been shown that their electrical conductivity is diminished when their temperature is raised. And the law of this diminution is expressed by the formula

$$K_t = K_0 (1 + a t + b t^2),$$

when  $a$  and  $b$  are constants, which are probably the same, for all pure metals, and  $K_0$  and  $K_t$  the electrical conductivities of the metals at temperature  $0^\circ$  and  $t^\circ$  Centigrade.

Liquids and fused conductors in general are opposite in their behaviour under the influence of temperature, thus their electrical conductivity is increased by a rise of temperature. And the laws of this increase is expressed by the formula

$$K_t = K_0 (1 + a t),$$

when, as before,  $a$  is a constant,  $K_t$  and  $K_0$  are the electrical conductivities at temperature  $0^\circ$  and  $t^\circ$  Centigrade.

Now the chemical decompositions which are effected by a voltaic battery have been explained by the well-known theory of Grothüss. Assuming that in every binary compound or substance which may be considered to act as such, one of the elements is electro-positive, whilst the other is electro-negative. Grothüss predicates that under the influence of the contrary electricities of these electrodes, a series of successive decompositions and recompositions from one pole to the other is effected in the liquid in which they are immersed. Hence the elements which appear free at the electrodes and do not recombine are those which are, so to speak, the terminal molecules.

This theory of Grothüss's can be applied to the acids, the salts, and to the metallic oxides.

But there were various objections lodged against this theory, and in overcoming the chief of these Clausius applied the theory which is now universally admitted by the leading physicists, and which explains the constitution of liquids. In a liquid there is vibratory, rotatory and progressive motion; the molecules have no fixed positions; they are in a perpetual state of separation and reunion. The hypothesis assumes that compound bodies and their elementary constituents coexist with each other in a liquid. Hence, when a current of

electricity passes through them it influences the motion of the molecules in such a way that certain of them pass to the positive electrode whilst others pass to the negative electrode, and their recombination is prevented. The current does not bring about the decomposition, but it *utilises* it to give definite direction to the particles which are already separated.

Now these interesting considerations explain why the electrical conductivity of a liquid increases with the temperature, for heat, as every student of thermodynamics knows, increases the velocity of the molecules; not in a direct ratio to the rise of temperature, because the number of collisions of molecules per unit of time is also increased, but a little more slowly than in direct ratio. It also follows that electrical conductivity increases with the concentration of the liquid.

Within the past few months a great deal of attention has been directed to the estimation of the electrical conductivity of fused salts and solution of salts.

Foussereau stated some time ago that in the case of fused salts there is a sudden change of conductivity at the melting point (vide *Comptes Rendus*, vol. xcvi., p. 1,325). This was accepted with some hesitation at the time. L. Graetz, a German physicist, has recently been investigating the truth of the assertion experimentally. He made use of the following method:—

A quantity of the salt which is to be examined is placed in a small porcelain crucible. The lid of this crucible is perforated with four holes, two of which serve for the introduction of the wires which lead to the electrodes, and the other two for those of the thermo element, which is used for measuring the temperature.

The crucible is placed in a large sand bath, and precautions are taken in order that the conducting wires may be kept hot, so as to prevent solidification of the fused salt on the electrodes and on the junction.

The sand bath is heated to considerably above the melting point of the salt, and then allowed to cool slowly, whilst simultaneous determinations of the temperature and of the conductivity are made from time to time.

The melting point is determined by a separate experiment. Graetz used this method in the case of a number of substances, and the results which he obtained serve to show that there is in no case a sudden change of conductivity at the melting point.

Tables are given for the conductivity of the following substances: the chlorides, bromides, and iodides of cadmium and zinc, lead chloride, lead iodide, potassium nitrate, cuprous chloride, stannous chloride, and antimonious chloride. These may be consulted in Gilbert's *Annalen der Physik und Chemie*, series [2], vol. xl., p. 18, where the reader will also find the theoretical aspect of the question discussed, particularly in connection with dissociation.

Solutions of the chlorides and nitrates of sodium, potassium and barium, of potassium bromide, chlorate and ferrocyanide, of sodium sulphate, magnesium sulphate and hydrochloric acid, were examined a short time ago by E. Kraunhals, who used an apparatus originally described by Ostwald. In his experiments, Kraunhals investigated the electrical conductivity of solutions of these substances at temperatures between  $18^\circ$  and  $100^\circ$  Centigrade.

The concentration—always, as we have seen, an important consideration in connection with conductivity—varied from 1 gramme equivalent per litre to 1 gramme equivalent per 1,000 litres.

We need not follow Kraunhals through the eight pages of results and deductions from them which he gives in the *Zeitschrift für physikalische Chemie* [vol. v., page 250]; it will be sufficient to state that these results show most conclusively that the higher the temperature the greater the increase in the molecular conductivity with rising dilution.

Kraunhals calculates the mean temperature coefficients for various degrees of dilution, and also the values of  $\mu_\infty$ ; that is, the conductivity for infinite dilution at the temperatures  $18^\circ$ ,  $50.3^\circ$ ,  $82^\circ$ , and  $99.4^\circ$  Centigrade.

The quotient  $\frac{\mu_0}{\mu_\infty}$  is found to decrease somewhat with

rising temperature, from which it is concluded that the influence of temperature on the degree of dissociation of electrolytes which, at ordinary temperatures and in moderately concentrated solutions, are strongly dissociated, is only slight.

The great increase in electrical conductivity with a rise of temperature is explained by Kraunhals by the decrease in the *viscosity* of the solution.

Chemical constitution undoubtedly affects in some way the electrical conductivity of solutions. This is evident from D. Berthelot's researches, recently described in the *Comptes Rendus*, vol. cx., page 703.

The various solutions examined by Berthelot contained 0.01 gramme equivalents of various substances per litre, and the measurements of conductivity were effected by means of a Lippmann's electrometer.

The three hydroxy benzoic acids are observed to possess different conductivities, the resistance increasing in the order—

Ortho-hydroxy benzoic acid			
Meta-	"	"	"
Para-	"	"	"

It is somewhat remarkable that the conductivity of the para-acid is practically identical with that of simple benzoic acid.

When the acids are treated with one equivalent of sodium hydroxide, the numbers obtained are approximately the same in all these cases : thus

Reduction of conductivity for the ortho-acid	=	$\frac{3}{4}$
" " " meta-	=	$\frac{7}{10}$
" " " para-	=	$\frac{2}{3}$

When a second equivalent of the alkali is added, the conductivities of the meta- and para-derivatives remain practically the same, but differ considerably from that of benzoic acid, since the second equivalent of alkali exerts an appreciable effect. A third equivalent exerts a smaller but still appreciable influence.

In the case of the ortho-acid (salicylic acid), the second and third equivalents of the alkali produce less effect than with the meta- and para-derivative. The maximum difference in the case of salicylic acid is reached on the addition of one equivalent of alkali ; but in the case of the meta- and para-acids this maximum is given by the second equivalent.

From these results an interesting chemical deduction has been made, namely, that in the ortho-acid the phenolic function is less energetic than in the meta- and para-acids, a result which agrees with the thermochemical measurements of Berthelot and Werner.

Berthelot first put forward his theory that the examination of electrical conductivity could be used as a means of investigating chemical and correlated physical properties in the *Comptes Rendus*, cix., p. 801, and he showed, for instance, that determination of electrical conductivity could be utilised for determining the condition of equilibrium between dilute saline solution and aspartic acid which combine the functions of a base and an acid.

There is another paper on this subject in the same volume of the *Comptes Rendus*, commencing at page 864, in which the electrical conductivities and the multiple affinities of aspartic acid are investigated.

The most recent work of D. Berthelot on the application of electrical conductivity, to the determination of various chemical facts, may be read in a paper contributed to the *Comptes Rendus*, vol. cx., p. 1,066. In this paper he gives the results of an investigation into the conductivities of the ammonium and aniline salts of the hydroxy benzoic acids.

Those who are interested in this new departure in electro-chemistry may also find a recent paper by C. A. Bischof and P. Walden worth reading. It may be consulted in the *Berichte der Deutschen Chemischen Gesellschaft*, vol. xxiii., p. 1,950. Here is described an investigation which they undertook into the conductivity of the substituted succinic and glutaric acids.

Tables are given showing the melting point and the values, as ascertained by them, of the dissociation constant. It appears that the tri-substituted succinic acids

have the least conductivity, and differ least amongst themselves. In the case of the glutaric acids the differences in the value of the constants were too small to allow of the deduction of any conclusion concerning the constitution of the different acids.

There is also a paper on the conductivity of the substituted succinic acids by Bethmann, in the *Zeitschrift für Physikalische Chemie*, vol. v., p. 385.

## THE VIBRATIONS OF A PLATINUM WIRE KEPT INCANDESCENT BY AN INTERRUPTED ELECTRIC CURRENT.\*

By M. ARGYROPOULOS.

I STRETCHED horizontally a platinum wire .7 of a metre in length and a fraction of a millimetre in diameter, and sent an electric current into it, in order to heat it to white heat. Observing the great dilatation of the wire during the passage of the current, I thought that some vibratory movement would be produced by successive interruptions of the current. I therefore introduced into the circuit a large trembler interrupter, or, better still, the interrupter proposed by Foucault for large Ruhmkorff coils ; the platinum wire immediately began to vibrate, subdividing itself into stationary waves.

We can observe very clearly one, two, three, and as many as eight, ventral segments separated by nodes which seem to be stationary. By very slowly lessening the tension of the platinum wire the number of these ventral points is increased ; on the other hand, if we slowly increase the tension, the number of ventral points is lessened, and the incandescent wire vibrates transversely, forming a single ventral segment in the middle.

The support on which I stretched the wire had two actions, one to stretch the wire more or less, and the other to lengthen or shorten it.

The experiment was performed in the following manner :—First, I took a long length of wire and sent through it a current of from 45 to 50 Bunsen elements, keeping the interrupter inoperative. Then the wire was shortened until it became incandescent. The interrupter was then set in motion and the wire began to vibrate. Then the wire was slowly stretched, until at last it vibrated as a whole, forming one single ventral segment in the middle. By lessening the tension of the wire I could produce as many as eight ventral segments, or even more.

This experiment enables us to illustrate before a large audience the vibratory movements of strings.

## A NEW APPARATUS FOR EXAMINING THE VARIATION OF ELECTROMOTIVE FORCE WITH TEMPERATURE.

A NEW apparatus—or, perhaps, more correctly speaking, a new *method* by means of which the seat of the variation of electromotive force with variation of temperature may be examined—has been devised by a German physicist, A. Gockel. It consists, in its essential features, as follows :—

Four cells are taken and placed at the corners of a rectangle ; these are joined up, according as they are required, along the sides of the rectangle by means of siphons, and filled with certain electrolytes.

The cells at one pair of adjacent corners, for example, contain a solution of zinc sulphate, and are provided with zinc electrodes, whilst the other pair of cells contain a solution of copper sulphate with copper electrodes.

\* Presented to the Académie des Sciences, by M. Cornu.

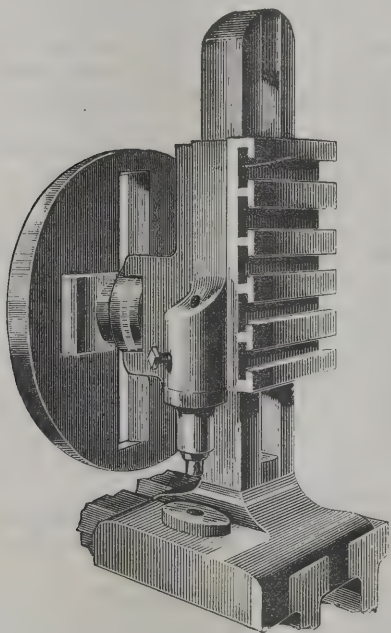

It is obvious that this arrangement gives, practically, two Daniell cells, one of which can be warmed in a water bath, whilst the other remains cold, the necessary connection being made by means of the siphons.

By suitable combination, the temperature co-efficients of the different contacts may be determined. Gockel shows that from these coefficients the temperature co-efficient of the whole galvanic element may be calculated by summation.

It is stated that the agreement between direct experiment and calculation is fairly satisfactory, and this assertion will give confidence to other observers who may be inclined to experiment with this apparatus.

### IMPROVED ATTACHMENT FOR LATHES.

THE apparatus shown in the accompanying illustration will be found a very useful adjunct to a lathe or any similar tool from which a vertical reciprocating motion can be obtained. It consists of a standard which is bolted to the bed of the lathe; upon this slides a grooved face plate, to which is secured the work to be toolled. This face plate is moved up and down by a roller mounted upon a pin bolted to the ordinary lathe chuck plate, which travels to and fro in the roller path formed upon the back of the slide; the length of stroke depending upon the distance of the roller pin from the mandril centre. By placing a cutting tool in the slide rest, and operating the feed screws by hand or by means of self-acting motion obtained from the slide, metals

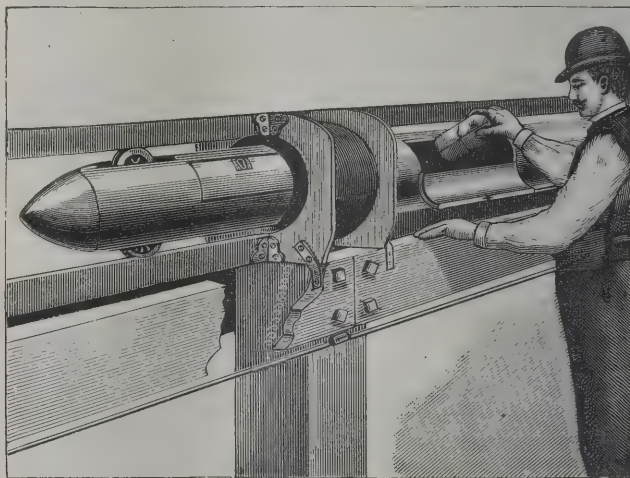

may be planed, shaped, key grooves cut, and a variety of other tooling work accomplished with accuracy and rapidity. For the convenience of light metal workers, a punch and pair of shearing blades can be added for cropping plates and roughing out material. The grooves upon the sliding face plate can, when desired, be replaced by a vice for holding the work, or a vice can be bolted to the grooved face plate. The illustration is taken from an attachment fitted to a 4-inch centre lathe, which has a stroke of three inches; a speed can be obtained of from 50 to 200 strokes per minute. The cost is very moderate. The attachment is patented, the inventor being Mr. F. M. Rogers.

**Department of Science and Art.**—Her Majesty has been graciously pleased to command that the Government institution now known as the Normal School of Science and Royal School of Mines shall in future be called the Royal College of Science, London.

### EXPERIMENTAL PLANT OF THE PORTELECTRIC SYSTEM.

IT is now something more than a year, says the New York *Electrical World*, since the exhibition of the model of the Portelectric system in the Old South Church in Boston. The subsequent description of this promising invention in the daily newspapers and technical journals attracted the notice of people in all parts of the world. It was at once recognised that, could the model be duplicated on a large scale, and be made to work with the same degree of success, its commercial utility and importance in the rapid transportation of mail and express packages would be very great. Since the invention was first exhibited to the public, its projectors have been busily engaged in the construction of an experimental track upon which the "portelectric" car could be tested under conditions similar to those which would be met in actual practice, and fully as severe as those which would be encountered in commercial operation.

This experimental plant, which is located near the Howard Street Station on the New York and New England Railroad, in the suburbs of Boston, has been completed and in experimental operation for some time, but its construction and operation have been open to the inspection of the public only since the 11th of this month. Notwithstanding the difficulties, mostly of a mechanical nature, which necessarily had to be met and overcome in pioneer work of this kind, the experimental work has proved so successful that the performance of the system re-enforces the opinions formerly held by its projectors concerning its future commercial importance.

The system is intended for the transportation not of passengers but of mail and express matter only at rates of speed approximating two miles per minute, the steel car being drawn along its confined path at this high rate by the pull of numerous solenoids through which the track is laid, each coil exerting its power for a short time only as the car approaches it. In general principles the experimental track here described and illustrated does not differ from the model exhibited in the Old South Church last year. In the mechanical details, however, such changes have been made as have been found by actual experience to be necessary to adapt the system to the requirements of commercial service. The method of closing and opening the circuit through the track solenoids at the proper time has been changed; the mounting of the car upon its wheels, the construction of the track and some other mechanical details have been greatly improved. Prof. A. E. Dolbear, the electrician of the company, and Mr. John T. Williams have given the matter almost daily attention for several months, and especial care has been directed toward the reduction, as far as possible, of the copper wire required in the coils of the track solenoids.

The experimental line is nearly 3,000 feet long, built in the form of an oval or somewhat of a pear shape, including two curves of different radii, some straight and level sections, and grades, both on a straight track and on curves. One grade is 8 per cent. and another 11 per cent. Posts 10 inches square are set solidly in the earth to a sufficient depth to be undisturbed by frost, and are packed about with sand. These posts project above the surface to a height of about 4 or 5 feet, and to their sides, at the top, are strongly bolted planks, 3 by 10 inches, set on edge and carefully fitted, so that the top of the planks is flush with the top of the posts. Posts are set at intervals of 6 feet. This low structure was so built simply for convenience of access in conducting experimental investigation.

A very neatly designed and well constructed power house stands directly over the track. The track passes directly through its centre at a distance of about 2 feet from the floor. The building is surmounted by a lookout tower, from which the car may be watched as it speeds around its half-mile course.

The power equipment of the station consists of a Sturtevant 20 H.P. engine and an Edco dynamo to furnish current for the propulsion of the car. This dynamo is wound for a pressure of 1,000 volts. A horizontal tubular boiler supplies steam for the engine and for the heating of the building as well. A small supply and work room is conveniently arranged in one corner of the building. The station is lighted by Bernstein series incandescent lamps, and the track is lighted when necessary with seven arc lights.

Upon the heavy framework of wood of which the track structure is composed are placed the solenoids, a series of coils extending along the entire track at intervals of 6 feet. These coils have an internal diameter of 11 inches, and are each made of about 20 lbs. of No. 14 wire. The two rails of the track extend through these coils, one at the top and the other at the bottom. The lower track is in connection with one terminal of the dynamo and the other terminal is connected with a lead wire parallel with the lower track. To this wire are attached branches connecting it to the various sections of the upper track, these sections being about six feet long. The passage of the car completes the circuit between the upper and lower rails through the solenoid in advance of the car, and the car is thus pulled into the coil until it is midway through the coil, when the current is cut out and transferred to the next coil in advance.

The car is an iron cylinder 10 inches in diameter and, with its conical ends, is 12 feet long and weighs 350 lbs. It runs on two wheels, and also has guide wheels to run on the track above the car. Doors upon its side allow of the necessary matter constituting the load of the car to be placed upon its inside and securely locked in place.

The greatest difficulty experienced in the operation of this track and car was in the adaptation of the car to the compound curve, made up of a grade and a curve of short radius. It was found necessary to make the car itself rotate to accommodate itself to the curve and grade; thus introducing a great frictional resistance. In spite of this, however, the car has been drawn about the oval track in about  $1\frac{1}{2}$  minutes, and its speed has reached about 45 feet per second. The greatest acceleration observed was about  $3\frac{1}{2}$  feet per second, which, if maintained for a minute would give a speed of about two miles per minute. The shape and difficulties of the present track, however, prevent the acquiring of such a speed.

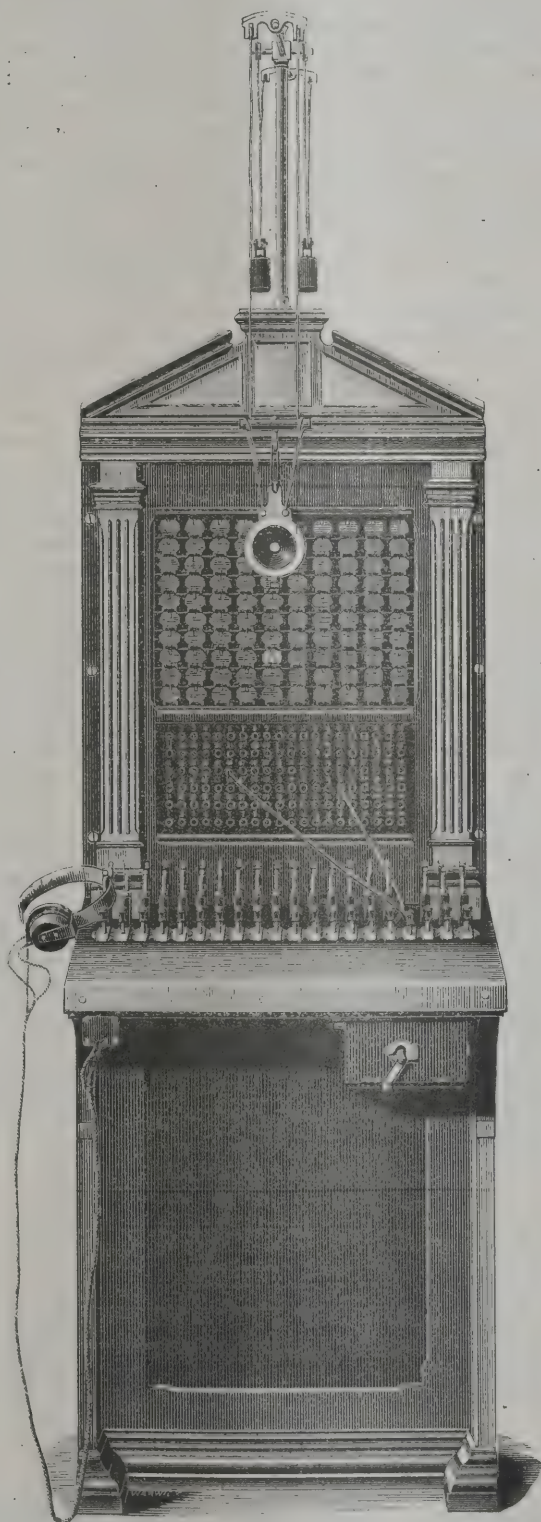

In forming an opinion of what has been already accomplished by the plant described above, it should be borne in mind that the whole project was so new that every step has had to be taken without the assistance of any precedent, or of the experience of others in similar work. Its growth, however, has been very satisfactory, and Prof. Dolbear asserts that there is every reason for thinking that in a short time the car will be capable of running away from the swiftest express train.

## IMPROVEMENTS IN TELEPHONE EXCHANGE SWITCHBOARDS.

By J. E. KINGSBURY.

THE subject of improvements in telephone exchange switchboards is of so much interest and importance that it cannot well be left at the point reached in the article on the subject last week.

I may first say that switchboards for small exchanges have not been neglected in the way the writer of the

article supposes. All the improvements in details which have been made in connection with multiple boards have been applied to the smaller boards so far as practicable, but it is quite true that the type of board remains very much what it was many years ago. I find this, however, simply a tribute to the prescience of its designers. The type I refer to is what is known all

over the world as the "Standard" switchboard, in which the two subscribers' indicators are cut off, "left idle," and a special ring off indicator inserted in the circuit of the pair of cords with which connection is made. This type of board is made from 25 subscribers upwards, for telephone exchange use. Smaller switchboards are not usually fitted with clearing out drops, but nevertheless only one of the subscribers' drops is left in circuit. The question of switchboards for exchanges is a large one and I cannot hope to do more than touch the fringe of the subject, but it is important that those of your readers who are not practical telephone men, and yet interested in telephony, should not be led to an incorrect conclusion by reason of the way in which the subject was dealt with last week.

A switchboard cannot be judged by itself. It is, or will be, one of a series making an exchange, and the exchange in its turn is, or will most likely be, one of a number constituting a telephonic system. A switchboard, then, must not only work well with the number of subscribers for which it is fitted, but must also be so arranged that further sections may be easily added as the subscribers increase; the whole work smoothly and quickly; and the electrical conditions be such as will interfere as little as possible with conversations from distant places.

The switchboard shown last week has a frontage of about 2 feet 6 inches. By the time the exchange had reached 120 lines there would be 4 sections covering a distance of 10 feet. Subscriber No. 1 would be on the extreme left, and No. 120 on the extreme right. If those two numbers were required to be connected, it could not be done with one operation. The cord is not sufficiently long, and if it were there are three other operators in the way. "Cross connections" therefore would be provided between the different boards, the work of connecting doubled, and the risk of error increased by the call passing through two hands. This system of cross connection is unavoidable in non-multiple exchanges, but in no case should it ever be necessary with so small a number as 120 subscribers. I would like to point out that it is not necessary to cover so large a space. The boards may be more compressed, but then the plugs are crowded. It is a choice of evils.

This type of board fails when considered as part of a series. Not only so, but it fails to come up to what is claimed for it when considered singly. The description says that because it only requires the plug of any line to be inserted in the jack of any other line to make a connection, it is plain that much less work is necessary than if a cord with a plug at each end of it were to be used for the purpose. At first sight it does seem so, but it is a fallacy nevertheless. Further on in the article the movements required are given in detail, and I transcribe them below in comparison with the movements required to make a connection with the board illustrated here, which is a double cord board:—

SINGLE CORD.		DOUBLE CORD.	
Insert general plug in No. 5 jack	1	Insert first plug into No. 5 jack (the operator's telephone is then in the line)	1
Take out general plug from No. 5 jack	1	Insert second plug into No. 10 jack and ring	1
Insert general plug in No. 10 jack and ring	2	Throw over lever of speaking key (which connects the two subscribers and disconnects the operator)	1
Insert No. 10 plug into No. 5 jack	1		
Take out general plug from No. 10 jack	1		
Total	6	Total	4

Instead of much less work being necessary, two movements more are necessary to make a connection on the single than the double cord board. The making of a connection is not all the work. The connection has to be unmade, and a comparison is not fair which does not include that also. When this is considered, the movements are equal in number, the single cord board requiring only one plug to be pulled out (1), whilst the double cord requires two plugs to be pulled out and a speaking key to be thrown over (3). It is not

to be supposed that these movements, though of equal number, are of equal value. The double cord movements are done much more quickly.

I think this will suffice to show that the saving of 30 per cent. in operators' work, which is claimed, is quite illusory, the balance is the other way.

But if there be no saving in operators' work, wherein consists the "Improvement"? It is not in facilities offered in other directions, for there are none. It is not in economy of first cost, for more material is used. It is not in saving of operators' wages, for the same number of subscribers takes a larger number of operators than a double cord board.

I am aware that there are advocates for these boards whose opinions are entitled to respect, but, unfortunately, opinion may be set against opinion. There is, probably, no subject which it is less safe to dogmatise upon than telephone switchboards. Circumstances do, undoubtedly, alter cases, and should be taken into account; but there are certain all-round requirements which have to be met, and it ought to be possible to demonstrate with reasonable precision in what way these boards are superior in design to their predecessors. The demonstration is not contained in last week's article. If I were to point out all the short-comings of the board and the errors of statement and deduction in the article, I might give the impression that my criticism was of a captious character; whilst, on the contrary, I am desirous only of contributing a few items of interest on a general question.

The board here illustrated is one of a type which the writer of last week's article does not allow for, *i.e.*, a double cord board without special clearing out drops, and yet only one drop left in circuit. It is for 100 subscribers, and is 23 inches wide. Thus 500 subscribers would occupy a space of less than 10 feet. It has some advantages, though in principle it is not better than the special clearing-out drop type. This latter enables the most suitable drop to be used for respective purposes, *i.e.*, those which would interfere with talking are "left idle," those which do not deleteriously affect talking are left in circuit. The designers of the standard switchboard recognised the fact which has been overlooked by their critics, that a telephone switchboard needed something more than a line of communication between one subscriber and another, and concluded that the most suitable place for the necessary apparatus was in the circuit of a pair of connecting cords. It is the absence of this necessary apparatus which makes the particular form of single cord board in question, clumsy in operating. If it were present, it would take up more room, and while increasing the cost, nullify the advantage. And here, I may say, that a single cord multiple board and the type of single cord board under discussion, are two distinct things. In the multiple board there is key-board room for all the apparatus needed and the apparatus is there.

## EDINBURGH EXHIBITION.

(Continued from page 407.)

"Silvertown" Dynamo and "Globe" Compound Engine.—The dynamo, which is capable of giving a continuous output of 350 ampères and 104 volts at 300 revolutions, has been designed for coupling direct to a high speed engine, and is so coupled to a Globe compound engine having cylinders  $8\frac{1}{2}$  inches and 15 inches diameter, by 8-inch stroke. The magnets are of the single horseshoe type, with pole pieces at the lower end, each vertical limb carrying a metal bobbin, on which is wound both series and shunt wire. The armature, which is of the ring type, has its core built up of thin annealed charcoal iron discs, insulated from one another by every alternate disc having a thin coating of special ebonite cured on. The discs are keyholed,

and carried by a four armed gun metal spider which, in turn, is securely keyed to the steel shaft. The armature winding consists of one layer of insulated strand cable, wound and connected on in the ordinary method to the commutator, which is built up of hard drawn copper segments, insulated with mica, and carried at each end by insulated gun-metal rings, fitting into grooves, turned in the commutator. The insulation of this ring is obtained by the use of ebonite, which is cured on to this ring to a thickness of about  $\frac{1}{8}$ th of an inch; and it has been found that this method has given much more satisfactory results than the old one of having separate insulating pieces. The rings fit on to a gun-metal sleeve, bored to fit the shaft, and the whole commutator is screwed up tight by nuts on this sleeve, so that it is complete in itself. There are three brush-holders on each spindle, each fitted with separate adjustments for pressure, and with hold-off catches. The brushes and holders are made of ample section, and each brush-holder is connected by a separate flexible conductor to the terminal board of the machine, to avoid the necessity of collecting the current through the contact between the holder and the spindle on which it is carried. The dynamo has been designed for continuous running in an engine room, the temperature of which is somewhat over 100° Fahr., and the rise of temperature has therefore been kept low; an actual test, made by placing the thermometer on the armature directly the machine was stopped, and noting the highest temperature recorded by the thermometer, showing a rise of 25° Fahr.

## REVIEWS.

*The Working and the Connections of Electric Telegraphs.* Compiled by Prof. Dr. KARL EDUARD ZETZSCHE, Engineer of Imperial Telegraphs, with the co-operation of several specialists; being, at the same time, the second half of the third volume of the *Manual of Electric Telegraphy*. Part 2, Section 3; *The Arrangements and Connections for Multiple Telegraphy*. Drawn up by Dr. A. TOBLER and Dr. E. ZETZSCHE. Halle on the Saale: W. Knapp.

The authors of this treatise deal with their subject in the most thorough-going manner. In the third section, with which the present volume begins, they explain the kinds of multiple telegraphy. They distinguish duplex telegraphy, *i.e.*, the simultaneous dispatch of two telegrams in opposite directions on the same line; diplex-telegraphy, the dispatch of two telegrams on one and the same line, but in the same direction, and, lastly, quadruplex-telegraphy, the dispatch of two telegrams on the same line in each direction. As regards the economical value of multiple telegraphy, it is remarked that in spite of the great number of devices proposed the system has not met with such wide application as might have been expected. There seems little prospect that as many messages can be dispatched by duplex telegraphy on a single wire as can be sent upon two wires by simple telegraphy.

The authors describe in the first place the duplex telegraphs for short lines, then those for long aerial lines, and, lastly, those suitable for cables. Under each of these heads the various kinds of instruments are described and shown in beautiful figures.

In duplex telegraphy in long aerial lines, well insulated, and still more in cables, the phenomena of charging constitute an obstacle.

Intermittent multiple telegraphy is discussed at great length, with special notice of the systems of Laborde, Munier, Brown, and La Cour. The work is evidently incomplete, the appearance of the concluding part being promised by the end of the current year. Still, we can have no hesitation in pronouncing it a treatise of great value to telegraphists and to electrical engineers in general.

*Practical Manual of the Installation of the Electric Light* (*Manuel pratique de l'Installation de la Lumière Electrique*). Par J. P. ANSEY, Electrical Engineer. Paris: Tignal.

This manual, after general rules for installation, treats of motors and their possible defects. Steam engines, gas engines, petroleum engines, hot air, compressed air and water power, are all described. Compressed air, on the system of Popp, seems to find considerable favour in Paris. Next follows a description of electrical machines, with an account of the properties which they ought to possess. We have then the installation, maintenance and care of the machines. Accumulators are described especially as adapted for lighting purposes by the Electrical Power Storage Company. The rest of the work is devoted to arc lamps, the Jablochhoff candle, glow lamps, and accessory appliances, the arrangement of the leads, special installations, *e.g.*, those of powder works, distilleries, mills, ships, light-houses, and theatres.

A special chapter lays down the duties of the various officials engaged in electrical works, and an appendix gives an abstract of the French laws, on the introduction and regulation of the electric light in theatres, music halls, &c.

The work is illustrated with 135 figures in the text, many of which, we are sorry to say, are strikingly bad.

*Traité D'Electricité et de Magnetisme; théorie et applications; instruments et methodes de mesure electriques. Cours professé à l'Ecole Supérieure de telegraphie.* By A. VASCHY, Ingenieur des Telegraphes, Répétiteur à l'Ecole Polytechnique. Vols. 1 and 2. Paris: Librairie Polytechnique, Baudry et Cie, 15, Rue des Saints-Pères.

These two volumes form an excellent treatise on electricity and magnetism. Theory, properly so called, forms the subject of the first volume; elementary principles are not dealt with, these being supposed to have been previously studied by the reader. In the second volume the application of electrical laws to telegraphy, telephony, and other subjects, is considered, electrical measurement being more particularly dealt with. The books being especially written for students studying telegraphy, the subjects of electric lighting, dynamos, &c., are not touched upon; we say "written for students studying telegraphy," but we imagine that this is only nominally so, for the nature of the whole treatise is far too deep to be of any practical value to an ordinary student, it being somewhat on a par with the "Electricity and Magnetism" of Clerk Maxwell; in fact, we should say that it is the very last work to recommend to such students. Generally speaking the two volumes may be described as a very excellent "boil down" of matter which is found scattered through numerous modern works, though we by no means say that there is not a good deal of original matter also. Although frequent references are made to authorities in foot notes, there is a very great deal of original information obtained from standard works of which no acknowledgement whatever is made. The author has taken great pains to keep to the front by giving the very latest information, and he does not deal with individual subjects at too great a length. Altogether we must express ourselves as much pleased with Mr. Vaschy's production, which does him great credit.

*Dictionnaire d'Electricité et de Magnetisme.* By JULIEN LEFEVRE. 2nd issue. Paris: J. B. Baillié et Fils, 19, Rue Hautefeuille.

We expressed a distinctly favourable opinion on the 1st issue of this dictionary; the 2nd issue commencing at "Electrolysable," and terminating at "Magnetometre," is equally good with the first. The whole work promises to be a very valuable compilation when complete.

*Tables to find the Working Speed of Cables, comprising also Data as to Diameter, Capacity, and Copper Resistance of all Cores.* By ARTHUR DEARLOVE. London: E. & F. N. Spon, 125, Strand.

Although but few books dealing with the subject of the electric telegraph are now issued, the subject of the electric light and the application of electricity for the purpose of power having carried all before it, yet occasionally productions are issued dealing with particular points in connection with telegraphic communication, some of small value, others of distinct utility. The small pocket-book before us decidedly belongs to the latter class. Up to the present, practically little reliable information has existed which was available when it was required to estimate what working speed could be obtained through a proposed cable of a particular type, or to estimate what type would be required to obtain any particular speed. This very necessary information can now be obtained with certainty by means of Mr. Dearlove's useful tables. The latter have been compiled from formulæ which have for some time been used by Messrs. Clark, Forde and Taylor (names which are a guarantee for correctness on a subject of the kind in question), and are based on mean results recently obtained in the commercial working of long cables. The starting point upon which the calculations are based are: 1st, the capacity of a cable whose conductor and dielectric are of equal weights is 355 microfarad per knot. 2nd, the temperature of a laid cable is 45° F., at which temperature each knot-pound has a resistance of 1,124 ohms. There are actually two tables in the book, the first giving all data with reference to cores of from 100 lbs. copper and 80 lbs. gutta percha to 500 lbs. copper and 500 lbs. gutta percha, the former giving, it may be mentioned, a speed of 26.6 words per minute (over a length of 1,000 knots), and the latter a speed of 147.7 words per minute. The second table gives dimension coefficients for various lengths of cable up to 4,000 knots, by which the working speed given in Table I. have to be divided. Of course in practice a clerk cannot read on a mirror instrument at a greater speed than about 25 words per minute, so that it is not to be understood that where a greater speed than this is shown by the calculations, this speed can actually be obtained, but only that the particular cable in question has a larger core than is necessary. This point might perhaps be shown a little clearer in the explanatory introduction, as it is liable we, think, to mislead. By the use of automatic transmitters and receivers very high speed working is possible under certain conditions. It would be interesting to know what this speed would be in practice on a 1,000-mile cable with 500 lbs. copper and gutta-percha, and which is calculated to give, with an instrument as sensitive as the mirror, a speed of 147.7 words per minute.

## BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—LEEDS, 1890.

### EXPERIMENTS TO DETERMINE WAVE VELOCITY IN CERTAIN DIELECTRICS.

By F. T. TROUTON.

(Read before Section A, September, 1890.)

THE method employed was described in *Nature*, February 21st, 1889, and depends essentially on interposing a sheet of the dielectric between the reflector and the resonator in Hertz's well-known experiment of electro-magnetic "loops and nodes." The effect of this is to move in towards the reflector the system of maximum and minimum sparking positions. The amount of the displacement thus resulting depends on the rate of propagation of the disturbance through the dielectric sheet.

In the experiments made the sheet was placed immediately in front of the reflector. The circular form of resonance was employed to determine the position of the "loops and nodes," and it was always held so as to be only effected by the magnetic component.

If the reflection, which occurs at both surfaces of the sheet, be neglected, ( $\mu$ ) the index of refraction will be found by dividing ( $l$ )

the thickness of the sheet into its air equivalent  $\mu = \frac{(x_0 - x)}{l}$  where  $x$  is the distance from the sheet to the first node or magnetic minimum position, and  $x_0$  the distance of the node from the reflector when the sheet is removed—that is to say, one-quarter the wave-length in air.

When the reflection from the surface of the dielectric is considered the expression for  $\mu$  is not quite so simple. If we suppose the metallic reflector in optical contact with the dielectric sheet, we can then sum up the multiple reflections resulting very much as in the well-known way of doing so for Newton's rings. Let the amplitude of the incident radiation be taken as unity, and let  $b$  be that of the reflection at the front surface of the sheet, and  $c$  of the part penetrating. This portion on reaching the metallic reflector is supposed returned, and at the front of the sheet is again divided; let the part reflected back to the metal be  $ce$ , and that sent out  $cf$ , and so on. The reflected wave is found by summing up these terms. If  $\sin \phi$  is taken to represent the incident radiation at the front surface of the dielectric, the total reflection then is  $b \sin \phi + cf \{ \sin(\phi + \delta) + \epsilon^2 \sin(\phi + 2\delta) + \epsilon^4 \sin(\phi + 4\delta) + \dots \}$ , where

$$\delta = 2\pi l \mu, m \text{ standing for } \frac{2\pi}{\lambda}. \text{ This can be written as } A \sin(\phi + 2m\pi r), \text{ when } \tan 2m\pi r = \frac{(1 - b^2) \sin \delta}{(2b + (1 + b^2) \cos \delta)}. \text{ This gives for } \mu, \text{ remembering that } b = \frac{(\mu - 1)}{\mu + 1}; \tan 2m\pi r = \frac{2\mu \sin 2m\pi l}{(\mu^2 - 1) + (\mu^2 + 1) \cos 2m\pi l}.$$

Here  $r$  is the equivalent distance in air, or  $r = x_0 - x$ .

Some experiments have been made with sheets of pitch, solid paraffin, sulphur, and plaster of Paris. In the case of pitch, the value of  $\mu$  calculated from the above results is about what would be expected, namely, about 1.7 (Hertz by means of his pitch prism found 1.69); but in the case of the others the calculated values of  $\mu$  are evidently much too large, those for paraffin and sulphur lying between 3 and 4. The area of the pitch sheet was 60 by 45 c., that of the paraffin and sulphur 60 by 29 c.; the thicknesses were 6.3, 3.5, and 3 c. respectively. The zinc reflector placed behind the sheets was the same size as the sheets. It may be due to the small sizes employed that these unsatisfactory results were obtained, the small size of the reflector introducing diffraction phenomena—that is to say, the first node is situated at more than  $\lambda/4$  from the reflector. This is due to the electrically-charged edges of the metal reflector. This is more fully referred to in *Phil. Mag.*, March, 1890. An approximate calculation of the action of such a reflector can be obtained by supposing it equivalent to a Hertz vibrator; in this way are obtained values for the velocity of the disturbance near the reflector greater than the normal. It may possibly be that these abnormal velocities (or whatever may be the true phenomenon which is equivalent to such) are effected in a greater ratio than the normal velocity is by the substitution of other dielectrics for air. In fact, taking Hertz's value for the

velocity at distance  $v$  as  $v = \sqrt{\frac{m^2 v^2 + 1}{m^2 v^2}}$ , we find something of the kind. For a dielectric whose index of refraction is  $\mu$ ,  $v_1 = \sqrt{\frac{m^2 v^2 \mu^2 + 1}{m^2 v^2 \mu^2}}$ ; and the value of the index at distance

$$v, \mu_v = \frac{v}{v_1} = \mu \left( \frac{m^2 v^2 + 1}{m^2 v^2 + \frac{1}{\mu^2}} \right). \text{ This gives } \mu_v \text{ as greater}$$

than  $\mu$  the normal value.

It must, however, be remembered that at the distances in the present case the formula can hardly be satisfactorily applied. The thing might be experimentally tested by placing the sheet at a little distance in front of the reflector. There is no question but that the employment of larger dielectric sheets and metal reflectors, so as to give the equiphasial surfaces plane instead of curved, will be the best solution of the main enquiry.

When there is a space left between the dielectric sheet and the reflector, the calculation is more complicated than before, owing to the reflection from the back of the dielectric as independent of the metal. In the following this distance is supposed nothing but the back reflection from the sheet left. The result can be written

$$\text{as } \tan 2m\pi r = \frac{A \sin \alpha + c \sin \gamma}{A \cos \alpha + c \cos \gamma}, \text{ where } A \text{ is the amplitude of}$$

the reflection from the dielectric sheet alone, the metal being removed, and  $\alpha$  the alternation in phase introduced; and where  $c$  is the amplitude of the point resulting from replacing the metal reflector, and  $\gamma$  the alteration in phase belonging to it.  $A$  and  $\alpha$  are found precisely as in Newton rings.

$$A^2 = \frac{2b^2(1 - \cos \delta)}{1 - 2b^2 \cos \delta + b^4} \tan \alpha = \frac{b^2 - 1}{b^2 + 1} \cot \frac{\delta}{2}.$$

To find  $c$ , let the transmitted beam be written as  $B \sin(\phi + \beta)$  when

$$\tan \beta = \frac{\sin \delta}{\cos \delta - b^2},$$

and suppose this returned by the metal reflector. Part of this will be transmitted by the sheet, and part sent back a second time to the metal. The part transmitted is  $B^2 \sin(\phi + 2\beta)$ ; the part reflected back to the metal is  $A B \sin(\phi + \beta + \alpha)$ . This is again reflected by the metal, and is again divided up. The part trans-

mitted is  $A^2 \sin(\phi + 2\beta + \alpha)$ ; the part reflected is  $A^2 \sin(\phi + \beta + 2\alpha)$  and so on. Then we have to solve

$$c \sin(\phi + \gamma) = B^2 \left\{ \sin(\phi + 2\beta) + A \sin(\phi + 2\beta + \alpha) + A^2 \sin(\phi + 2\beta + 2\alpha) + \dots \right\}$$

and summing up we get the values of  $c$  and  $\gamma$ . Putting in for the sines their exponential values and recollecting that  $B^2 = (1 - A^2)$

$$\text{we get } c^2 = \frac{(1 - A^2)^2}{1 - 2A \cos \alpha + A^2} \text{ and } \gamma = 2\beta + \tan^{-1} \frac{A \sin \alpha}{1 - A \cos \alpha}.$$

The calculations of  $\mu$  from this result is practically the same values as given above. In the case of some substances it was found quite impossible to make a determination of  $\mu$  after the method described, as they afforded of themselves such strong reflection. Glass even 2 c. thick gave considerable reflection, as did also a limestone flag 2.5 c. thick. Slate and sandstone gave reflection, but not so strong as the other two. A sheet of coal 2.5 c. gave very slight reflection, but a sheet of thin battery carbon reflected like metal. No reflection could be obtained from ebonite 2.5 c. thick, shellac 2 c., or tallow, pitch, paraffin, or sulphur. This reflection is doubtless due to absorption of the beam reflected from the back surface, which thus weakened cannot sensibly interfere with that from the front surface. Owing to the nature of the apparatus and the fact of its constantly changing in sensitiveness, no precise measurements are possible, but a considerable number of comparisons between different substances were made in this wise. The resonator was set so as to only just spark on placing, say, a sheet of glass behind it as reflector, then quickly a sheet of, say, sandstone, and again glass. In this way it could be found that while glass caused sparking the sandstone did not. A cell (adjustable as to thickness) made of cardboard, which could be filled with various substances in a broken up state, such as quartz, sand, chalk, lampblack was tried. When 2 c. thick no reflection, or hardly any, was found with sand, fair reflection with chalk, and lampblack gave as "good as the limestone flag." Before the chalk was well dried it seemed to give stronger reflection. These sheets were about 1 foot square. Some quantitative method, such as that used in Germany by Rubens and Bitter, but which could be applied on a small scale, would be desirable, for these experiments are necessarily of the very roughest sort.

## LONDON COUNTY COUNCIL.

THE weekly meeting was held on Tuesday at Spring Gardens, Sir John Lubbock in the chair.

The Highways Committee reported that they have considered the question whether the council should be advised to again attempt to obtain control over the overhead wires in the County of London. It will be in the recollection of the council that the Bill introduced for this purpose last session was, after having been amended and passed by the select committee, rejected by the very small majority of three in the House of Commons, the voting having been 200 for and 203 against, notwithstanding that the chairman of the Select Committee and the chairman of Committees of the House fully explained the Bill, and supported the decision of the Select Committee. The committee are of opinion that the Bill, having received the approval of a Select Committee, should be again submitted for the consideration of Parliament, and they therefore recommend—

That the council's Bill relating to overhead wires, in the form in which it passed the Select Committee of the House of Commons, subject, however, to such modifications as the Parliamentary Committee may consider necessary, be again introduced into Parliament next session; and that it be referred to the Parliamentary Committee to give the requisite notices, and to take other measures necessary for the purpose.

The committee have considered three notices of the London Electric Supply Corporation, as follows—

6th October, 1890 (Registered No. 120), of intention to lay distributing mains in Waterloo Bridge Road and Westminster Bridge Road (1 plan).

6th October, 1890 (Registered No. 121), of intention to lay distributing mains in Westminster Bridge Road, Waterloo Road, Borough Road and Borough High Street (1 plan).

6th October, 1890 (Registered No. 122), of intention to lay distributing mains in Blackman Street, Newington Causeway, Newington Butts, and Walworth Road (1 plan).

These notices relate to works of the same character as those approved by the council on previous notices of this company; and the committee recommend—

That the sanction of the council be given to the works referred to in the notices (Registered Nos. 120, 121 and 122), each dated 6th October, 1890, of the London Electric Supply Corporation, upon condition that the company do give two days' notice to the council's engineer before commencing the work; that the mains be laid under the footways, and be kept 9 inches below the under side of the pavement, wherever it is found practicable to do so; and that where the mains cross the carriageways they be kept at the same depth below the concrete, or the road material, as the case may be.

The committee have also considered a notice, dated 9th October, 1890 (Registered No. 123), from the Notting Hill Electric Lighting Company, of intention to lay three 2-inch pipes across Holland

Park, from No. 39 to No. 76 (1 plan); and a further notice (Registered No. 124) from the company, bearing the same date, of intention to lay a 15-inch culvert on the east side of Pembridge Gardens, from No. 4, Pembridge Square to No. 74, High Street, Notting Hill (1 plan), in substitution for the works in Pembridge Gardens already sanctioned by the council (Registered No. 108). The proposed works appear to be unobjectionable; and the committee recommend—

That the sanction of the council be given to the works referred to in the notices (Registered Nos. 123 and 124) of the Notting Hill Electric Lighting Company, each dated 9th October, 1890, upon condition that the company do give two days' notice to the council's engineer before commencing the work; that the cover-stones of the culverts under 20 inches wide shall be not less than 2 inches thick, and of the wider culverts not less than 2½ inches; and that, where the culverts cross the carriageway, there shall be at least 9 inches thickness of Portland cement concrete above the cover-stones of the culvert, in addition to the road material.

The Kensington and Knightsbridge Electric Lighting Company has given a notice (Registered No. 125), dated 8th October, 1890, of an intended small extension of mains in Hyde Park Gate (1 plan). There appears to be no objection to this; and the committee recommend—

That the sanction of the council be given to the works referred to in the notice (Registered No. 125) of the Kensington and Knightsbridge Electric Lighting Company, dated 8th October, 1890.

## NOTES.

**The Electric Light in Barcelona.**—The electro-technical journal *Los Anales de la Electricidad*, of Madrid, does not look very favourably upon the scheme for lighting (7,000 incandescence lamps), the town of Barcelona by means of Ferranti dynamos, working at 10,000 volts, underground cables, and transformers. The high potential is objected to because, it is said, that the Deptford scheme has not yet proved a success, and underground cables are taken exception to, such a system being next to impossible in Barcelona where no large sewers exist, and where the ground under the narrow streets contains a perfect network of gas and water pipes, and small drains.

**The Electric Light at Bournemouth.**—At a meeting of the Bournemouth Commissioners last week a letter was read from Messrs. Learoyd, James & Mellor, applying for consent to a provisional order being granted to their client's, The National Electric Supply Company, Limited. A committee recommended that consent be given, subject to the order being approved by the Commissioners. It was stated that there were already two companies with provisional orders, one of whom, however, had made no sign of acting upon it. The matter was referred back to the committee. A letter was read from the Brush Electrical Engineering Company, intimating their intention of shortly commencing to lay their wires underground.

**The Electric Light in Cornwall.**—The Penzance Town Council have been asked to accede to the application of the Penzance Electricity Supply Company, for the grant to them of a provisional order, but after consideration they have adopted the recommendation of the Lighting Committee, that the Council should themselves take steps to obtain an order with a view to entering into a contract with a company to carry out the works.

**Croydon and Electric Lighting.**—The town authorities are making application for a provisional order.

**A Generous Bequest.**—The late Dr. Muirhead, of Lanarkshire, has left the bulk of his estate to be applied to founding and maintaining an institution to be called the Muirhead College for the instruction and education of women in medical and biological sciences, whereby they may be trained to become medical practitioners, dentists, electricians, and chemists. The testator appointed fourteen ladies and gentlemen as executors. It is expected that the estate, which is chiefly in land, will realise about £30,000.

**The Argentine Cables.**—The journal *La Nacion*, of Buenos Ayres, contains a paragraph concerning the concession of the proposed cables between the Argentine Republic and Europe. As many of our readers have a certain interest in this scheme, we translate the paragraph for their benefit:—"Bieckert and Company's Cables.—On the occasion of the drawing up of the final deed of contract referring to the concession which, by the law of the 8th November, 1889, was obtained by Messrs. Emilio Bieckert & Co. for the laying and working of a telegraph cable to Europe, a difficulty was met with, which may result in the annulling of the contract signed by ex-President Juarez. This circumstance should not be necessary in order to induce the Government to abandon an enterprise which, at a cost of 11 millions of gold dollars, bearing an interest of 5 per cent., lays a burden upon the national treasury. The condition to which a spendthrift administration has brought the country does not sanction the contracting of engagements of this nature, more especially since there already exist abundant facilities for telegraphic communication with the whole world. The entering into contracts of this kind would be a repetition of censurable actions, and would produce the most adverse expressions of opinion. The present administration, which is waging war against dishonest *employés*, will, we are sure, continue it with the greatest determination against those concessions whose aim is the building up of private fortunes at the expense, and to the ruin, of the interests of the community."

#### Recent Interruptions and Repairs to Submarine Cables and Land Lines:—

Cape St. Jacques (Saigon) and Thuanan (Huë) ... ..	21st " "	Still interrupted.
Land-lines.		
Guatemala ... ..	26th July, 1890.	7th Oct., 1890.
Moulmein—Bangkok ... ..	4th Oct., " "	8th " "

**Communication with Turks' Islands.**—The Halifax and Bermuda Cable Company has issued a notification in which it undertakes to transmit by post telegrams for Turks Islands (West Indies), which may be sent *via* Bermuda. The telegrams will be posted at Bermuda on or about the 18th of each month, and an additional charge of one shilling per postage will be made on each telegram. The words "Post Bermuda" should be added to the address of every telegram.

**Increase of Plant at Bradford.**—To meet the increasing demands for the electric light at Bradford the Corporation is now having an additional Willans's engine of 300 I.H.P. put down. The engine is coupled direct to a Siemens's dynamo capable of developing 240 E.H.P. The new work is being carried out by Messrs. Siemens Brothers, and the same firm has also in hand the laying down of additional feeding and distributing mains. A set of storage cells is also being supplied. These have been supplied by Messrs. Crompton, Howell & Co., and they have a capacity of 1,000 ampère hours. These cells are intended to meet whatever demand there may be for light in the still hours of the night and morning. At 10 a.m. they will be thrown out of use by the starting of one of the engines and dynamos, and in the evening, when the demand for light is at its height, the corporation, during the coming winter, will be in a position to turn on four engines and dynamos, the united output of which will equal 600 E.H.P.

**Advice Gratis.**—In a leaflet which the "Medical Battery Company, Limited," gets inserted in a number of "serious" journals, we read:—"Beware of Bogus Appliances." Perhaps Mr. Harness, or some one of his physicians, surgeons, and electricians has by mistake put on the magic cap, which had the inconvenient property of causing its wearer to speak the truth.

**The ss. "Silvertown."**—This cable ship, which left the Thames on October 11th, arrived at Las Palmas, Gran Canaria, on October 18th. She left this port, after coaling, on October 19th, for Valparaiso.

**The Arc Musical Society.**—This society, composed of members of Mr. Ronald Scott's works at Acton Hill, opened its second season of smoking concerts on the 21st inst., at the Lyric Hall, Ealing, the concert being preceded by a dinner to which nearly 60 sat down. Mr. A. H. Tripp, the popular and ever energetic honorary secretary, to whom a vote of thanks was proposed by Mr. Scott, received quite an ovation, the general success of the society and of the dinner that night being entirely due to Mr. Tripp's personal exertions.

**Owen's College, Manchester.**—A prize of £10 has been offered by Mr. William Mather, M.P., for the best essay on some subject connected with the technical application of electricity, the competition being open to students working in the physical laboratory of the Owen's College during the day or evening. The award is to be given at the end of the present session, and Dr. Edward Hopkinson has offered a similar prize, to be awarded next session. The subject for the present session is "Recent Progress in the Science of Magnetism."

**The Southampton Electric Light and Power Company, Limited.**—At the last meeting of the Southampton Town Council, a letter was read from the Board of Trade, enclosing a letter from Messrs. Deacon, Gibson and Metcalf, of 4, St. Mary Axe, London, stating that the nominal capital of the company is £30,000, divided into 4,000 preference and 2,000 ordinary shares of £5 each. 577 ordinary shares had been taken up, and on these £1,071 had been paid. The company had issued debentures to the amount of £2,100 for the purpose of satisfying liabilities under a contract between the company and Crompton & Co, Limited, for the supply of plant and mains for the purposes of the undertaking. The only liabilities of the company were the solicitors' costs to date, and the liabilities under the above-mentioned contract. The Board of Trade asked for any observations the council might wish to make, and the letter was referred to a committee. It was stated that the company had already commenced the work, and that everything would have to be done to the satisfaction of the borough engineer.

**Presentation to Mr. A. R. Bennett.**—On October 23rd a deputation, consisting of about twenty of the National Telephone Company's *employés* in Scotland, comprising all the principal district managers and engineers, waited on Mr. Bennett and presented an illuminated address, recapitulating his services to the company during the eight years of his administration as general manager of their affairs in Scotland, and expressing regret at his resignation and good wishes for the future. The address was accompanied by a costly set of Sir William Thomson's electrical testing apparatus, manufactured by the India-Rubber, Gutta-Percha, and Telegraph Works, of Silvertown. The presentation was acknowledged by Mr. Bennett in suitable terms, and he was afterwards entertained to luncheon at the Windsor Hotel, Edinburgh.

**Signs of the Times.**—Owing to the enormous increase in business at the Acton Hill Electrical Works, Mr. Ronald Scott has been compelled to replace his gas engine by a steam engine developing 200 horse-power.

**The O. S. A.**—An ordinary general meeting of the Old Students' Association of the City and Guilds of London Institute, will be held at Finsbury Technical College, on Thursday, November 6th, 1890, at 8 p.m., when an address on "Industrialism" will be delivered by the President, Mr. W. B. Esson. This should be the means of attracting a large muster of members and friends.

**Patriotism and Telegraphy.**—French people have the reputation of being frivolous. Of all free and easy places Bougival, a pretty Parisian suburb, is one of the most celebrated, being a favourite resort to “canotiers” and “baigneurs” (and principally “baigneuses”). Still, Bougival is not behind in anything heroic. Last Saturday, 26th October, saw the annual commemoration of the deaths of three inhabitants, sacrificed in “l’Année Terrible,” victims of their devotion to their native country. One of these three braves, “Father Debergue,” as he was commonly known and called, was an uneducated person, aged seventy, who, not being able to take an active part in the defence of his invaded country, made it his business to interrupt telegraphic communications between the headquarters of the Prussian army at Versailles and an advanced post at Bougival. Many times did this patriotic old fellow cut the wire with his pruning knife without being detected, but at last he was caught in the very act. Taken before a court martial, he was condemned to death. The officer presiding, taking in kind consideration the advanced age of the culprit, offered to pardon him, provided that he swore never to do it again. Old Father Debergue proudly answered: “I am a Frenchman, and if I get free I will do it again.” A few minutes later he was shot along the wall.

**Edinburgh Exhibition.**—A petition was presented to the Court of Session on Tuesday last for the liquidation of the Edinburgh Exhibition. It is computed that the deficit will be about £40,000, the guarantee fund amounting to only £27,000.

**Institution of Electrical Engineers.**—The students will hold their next meeting on Friday, 7th November, when it is hoped that members will do their utmost to attend.

**Telephony in Parisian Suburbs.**—At the present time suburban districts are connected by telephone with Paris, and shortly six more suburbs will be also united to the Paris network. In addition to these, eight other communes are negotiating with the Administration in order to be telephonically connected with the city exchanges.

**Electric Tramway in Prague.**—It is proposed to lay down an electric railway in the exhibition which is to be held in Prague next year. The line will be about half a mile long, and will be of narrow gauge. It has not yet been decided whether to employ the accumulator or direct system of supply.

**Electric Light Fittings for Clubs.**—“The Cavalry” fittings, in Piccadilly, have throughout been designed and manufactured by Messrs. Faraday and Son, of Berners Street. The same firm has also designed the quaint brackets with sacristy lamps, in Venetian silver, which heralded the first night of “La Cigale,” under the new management at the Lyric Theatre.

**The McKinley Bill.**—This new tariff of the United States of America may be obtained from Simpkin, Marshall, Hamilton, Kent & Co., Limited, of Stationers’ Hall Court and Paternoster Row. It is “an Act to reduce the revenue and equalise duties on imports and for other purposes,” and it might be to the interest of anyone having dealings with America to invest 2s. in the purchase of the Act, or a copy may be seen at our office.

**Ship Lighting.**—The official trial trip of the ss. *Innaminka*, built by Messrs. Napier, Shanks and Bell, Yoker, to the order of Messrs. Elder, Smith & Co., London, on behalf of the Adelaide Steamship Company, Port Adelaide, Australia, took place on Saturday. The *Innaminka* has been handsomely fitted with all modern improvements, including electric light and electric bells.

**Paris Complaints against the Telephone Working.**—We take the following from *Le Soleil* of Tuesday:—“We draw the attention of the Higher Administration of Posts and Telegraphs to the bad working of the telephone lines in the interior of Paris. When complaints are made of the slowness of communications the *employés* reply that they can do no better on account of the insufficiency of the staff. If this be so, there is an urgent necessity to remedy a state of things which cannot fail, by its prolongation, to lead to the loss of a large number of subscriptions. Many subscribers only ask for one or two communications per day. They find that 400 francs per year is rather a large sum for losing daily an hour of their time.

**National Telephone Company Appointment.**—Mr. John D. Miller, district manager of the National Telephone Company, Limited, Dundee, has been appointed the company’s general manager for the division of Scotland north of the Forth, with offices at 13, Panmure Street, Dundee.

**Elmore Copper, &c.**—We have received a long letter, too late, however, for insertion in this issue, from Mr. W. Stepney Rawson, replying to our recent articles on Elmore Copper and Electro-deposition. It is evidently written in a moment of hot haste, and, says Mr. Rawson: “If I am incorrect in any of my statements you will publicly make the same known, but if not, it will only be left for your readers to conclude that you have made an unwarrantable attack upon a new industry without such knowledge of the matter as alone could justify you in doing so.” As our correspondent lays himself open to correction in almost every paragraph, we cannot reasonably refuse to gratify his desire to place his mistakes on record.

**Accumulator Explosions.**—The stupid conclusions at which the writer of that classic note on “Accumulator Explosions” arrived in the *Daily Telegraph*, and which we quoted last week, has already had a baneful effect, for we notice both daily and weekly papers of the “Society” kind commenting upon these little mishaps in the same way.

**General Electric Company.**—This company has sent us a copy of the latest edition (the fifth) of its electric light catalogue. Comparing it with the fourth edition, which was published only 18 months ago, we notice that its size, contents, and even weight are enormously increased, a fair indication, probably, of the extension which electric lighting has experienced in the period we have just passed through. The new edition of the catalogue contains every requisite for electric light installations of the most extensive character, both as regards central stations and private plant. The company considers it to be the most complete catalogue of electric plant which has been printed in any country, and has evidently spared no trouble and expense to make it perfect in every detail. Not only are the latest improvements and inventions included, but an endeavour has been made to reduce prices in accordance with standards ruling in the market at the present date. As a book of reference, we are told that the former issue of this catalogue has been much appreciated by engineers, architects and others who have had to make out estimates, and the present edition will certainly be found useful in estimating for plant and in ordering, both in England and abroad. It contains 126 pages and over 1,000 illustrations, and gives prices of, amongst others, the following articles:—Dynamoes, lamps, cables, switches, cut-outs, electricity and other meters, glassware, brass, copper, and iron fittings, casings, engines, motors, accumulators, &c.

**Lighting of Aldershot Camp.**—The authorities are considering the question of lighting the camp at Aldershot by electricity, and experiments will be shortly made.

**Electrical Engineering Corporation, Limited.**—Following the advent of a new addition to the board of this Corporation, notified in our City news, we learn that for the past nine months considerable extensions of the works at West Drayton have been progressing and are now complete. In the course of a week new machinery will be in operation, amongst the machine tools being some of the largest employed in the electrical industry.

**Hanley Electric Lighting.**—The corporation has decided to act on the recommendation of the committee to apply for powers to light the town by electricity.

**Glasgow Technical College.**—In Prof. Jamieson's evening classes alone in the Technical College about 150 "Electric Lighting" students have already been enrolled.

**The Latest Form of Advertising.**—One of the partners in a well-known firm of electric wire manufacturers on this side has just received a letter from America containing a faded flower, and couched in the following terms:—"Take back the flower thou gavest. I love you no longer; all my affection is now given to American Electrical Works, Providence, R.I., because they make such *beautiful* insulated electric wire.—I am no longer yours, MAUDE."

**The City and South London Railway.**—This electric railway is to be opened on Tuesday by His Royal Highness the Prince of Wales. We hope in our next issue to give full particulars of this, the first *electric railway* in England, which we trust may prove to be successful from all points of view.

**Alternating Current Lighting in Baltimore.**—The Brush Electric Company, of Baltimore, is increasing its alternating current plant, Westinghouse system, up to a capacity of 20,000 16-C.P. lamps, and when the additions and extensions are completed, there will be only two cities in the United States possessing larger systems of incandescent lighting, by alternating currents, than Baltimore, namely, Pittsburg, with 60,000 lights, and New York, with 50,000.

**Cremation Outdone.**—A young *savant*, Dr. Variot has just found out (?) that human bodies can be electrically mummified, and the Académie des Sciences is very shortly to be treated to exhibitions of the metalised bodies of newly born children. We believe that similar schemes were years ago exploded. Touching upon the subject, Dr. Variot claims that, by his (?) process, he can perpetuate, in the shape of authentic figures, *i.e.*, the very bodies (metalised) of the subjects which it is desired to so hand down to posterity by merely submitting them to the process of galvanisation. We are afraid that popular sentiment would be greatly against the adoption of such a scheme, as in the majority of cases the impression of features after death would give no true indication of what they were in life.

**The Progress of Civilisation.**—We are indebted to the *Referee* for the following information concerning the backward state of this country so far as scientific matters are concerned:—"Switzerland is far ahead of England so far as the application of scientific ideas and discoveries is concerned. In the smallest town in Switzerland you have the electric tram, the electric light, and the public telephone. Even up the valleys, in villages miles from a railway station, you can go into a tobacconist's shop, buy a halfpenny cigar, and use his telephone for nothing, and the old gentleman who sells baked chestnuts at the corner of an alley in the poorest quarter of a tenth-rate town has the electric light laid on over his stall; and yet in London, until the Swiss brothers took the matter in hand, the electric light was looked upon as something only fit for a Baron Rothschild or a Duke of Westminster to play with in his private house." Would it not be better that our sporting contemporary should confine itself to matters which its editors are able to understand?

**The Electric Light in Madrid.**—On the evening of October 19th, the inauguration of the new works of the Electricity Supply Company, was made the occasion of a banquet at which were present many influential persons. The works are situated close to the railway station of Las Delicias. The principal portions of the building are occupied by the machine and boiler rooms, each 132 feet long by 60 wide, the first containing 6 engines, exciters and dynamos, the second, 6 large boilers. The lighting is calculated to be sufficient for 24,000 incandescence lamps. In addition to the usual offices, test-rooms, workshops, &c., some space is devoted to an exhibition, intended to be permanent, of a complete system of house lighting, showing not only the technical or scientific apparatus in use, but also a great variety of what may be termed the more ornamental portions of an installation.

**Traction in Vienna.**—The Vienna Tramway Company has just submitted to the Minister of Commerce a project for the transformations of the present tramway system in that city. The scheme comprises the separation of the Ring traffic from the radial traffic, the working by electricity of the Ringstrasse tramway service, and the construction of a narrow gauge underground electric railway, which would traverse the town in two directions, namely, from the Schottenring to the Stubenring, and from the Burgring to the Ferdinandsbrücke and Aspernbrücke. The larger portion of this railway would comprise a tunnel in which a single track, 1 metre gauge, would be laid. Stations with double lines would be built at distances of from 325 to 540 yards, so that a three minutes' service in either direction could be effected. The tunnel would be lighted electrically, and it would be possible for a passenger to travel across the town in five minutes. The tramway company are prepared to construct this underground line as an integral part of the tramway system. The first steps which would be taken would be the introduction of electric traction on the Ringstrasse tramway by means of an underground conductor system.

#### NEW COMPANIES REGISTERED.

**D. Glasgow Huxley and Company, Limited.**—Capital, £1,000 in £10 shares. Objects: To trade as chemists and druggists, herbalists, and oil and colourmen, and to manufacture and deal in surgical, electrical, photographic, and other scientific instruments and requisites. Signatories (with 1 share each): D. Glasgow Huxley, Hy. D. Huxley, Isabella Huxley, Eliza Huxley, and Mary Howison, all of Sheffield; H. Barrow and Walter Balby (engineers), of Attercliffe. Registered, without special articles of association, by R. J. S. Douglas, 4, Æolian Villas, Muswell Hill, N. Registered office, 178, Cemetery Road, Sheffield.

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Kidderminster Electric Light and Power Supply, Limited.**—The statutory return of this company, made up to the 16th inst., was filed on the 20th inst. The nominal capital is £1,000, divided into 900 ordinary and 100 founders' shares of £1 each. Seven founders' shares are taken up, and upon these no call has yet been made. Registered office, Westminster Chambers, 5, Victoria Street, S.W.

**East Coast Electric Light and Power Supply, Limited.**—The statutory return of this company, made up to the 16th inst., was filed on the 20th inst. The nominal capital is £1,000, divided into 100 founders' and 900 ordinary shares of £1 each. Only seven founders' shares are at present taken up, and upon these no call has yet been made. Registered office, 5, Victoria Street, S.W.

**Barry and Cardiff Electric Light and Power Supply, Limited.**—The statutory return of this company, made up to the 16th inst., was filed on the 20th inst. The nominal capital is £1,000 in £1 shares, but seven founders' shares are all at present taken up; upon these no call has been made. Registered office, 5, Victoria Street, S.W.

**Devonshire Electric Light and Power Supply, Limited.**—The statutory return of this company, made up to the 16th inst., was filed on the 20th inst. The nominal capital is £1,000 in £1 shares, but only seven are at present taken up, and upon these no call has been made. Registered office, 5, Victoria Street, S.W.

**Camberwell and Islington Electric Light and Power Supply, Limited.**—The statutory return of this company, made up to the 16th inst., was filed on the 20th inst. The nominal capital is £1,000 divided into 900 ordinary and 100 founders' shares of £1 each. Seven founders' shares are taken up, but no call has been made thereupon. Registered office, 5, Victoria Street, S.W.

**Stamford Hill, Tottenham and Edmonton Electric Light and Power Company, Limited.**—The statutory return of this company, made up to the 16th inst., was filed on the 20th inst. The nominal capital is £1,000 divided into 900 ordinary and 100 founders' shares of £1 each. Seven of the latter are taken up, but no call has been made thereon. Registered office, 5, Victoria Street, S.W.

**Provincial Electric Light and Power Supply, Limited.**—The statutory return of this company, made up to the 16th inst., was filed on the 20th inst. The nominal capital is £1,000 divided into 900 ordinary and 100 founders' shares of £1 each. Seven of the founders' shares are taken up, but no call has been made thereon. Registered office, 5, Victoria Street, S.W.

**Vaughan Sherrin Electrical Engineering Company, Limited.**—At a meeting of the subscribers to this company, held at 48, Eagle Wharf Road, Islington, on the 15th inst., it was proposed and carried that the number of directors shall be four, and that the first shall be John Ramsay L'Amy, J.P., D.L., of 107, Cromwell Road, S.W.; Lieut.-Colonel Elphinstone Dalrymple, of 6, Gledstone Road, West Kensington; Herbert Woodgate, of 123, Pall Mall; and J. Vaughan Sherrin, of 3, Codrington Road, Hampstead.

**Norwich Electricity Company, Limited.**—The registered office of this company is now situated at 1, Old Bank of England Chambers, Queen Street, Norwich.

**Electro-Chemical Syndicate, Limited.**—The registered office of this company is situated at Monument Buildings, E.C.

**Leeds and London Electrical Engineering Company, Limited.**—The registered office of this company is situate at 117, Bishopsgate Street Within.

## CITY NOTES, REPORTS, MEETINGS, &c.

### The Monte Video Telephone Company, Limited.

THE following report will be presented to the shareholders at the annual general meeting, to be held at the offices of the company, at 12 noon to-day. The statement of accounts for the year ending 31st July last, shows a gross profit of £10,301 5s. 9d., after providing for all working expenses in Monte Video and London. Off this sum there has been written £114 14s. 8d. for preliminary expenses, and £19 10s. 10d. for depreciation of furniture, leaving a balance of £10,167 0s. 3d. To this must be added the balance from last year, £325 8s. 5d., making a total now to be dealt with of £10,492 8s. 8d.

The directors recommend that of this amount the full dividend of 6 per cent. on the preference shares amounting to £8,308 7s. 2d. be declared, that £1,000 be added to the depreciation fund, and that the balance £1,184 1s. 6d. be carried forward. An interim dividend on the preference shares was paid in March last.

During the year the sum of £5,600 6s. 7d. has been expended on

capital account, chiefly in consequence of the completion of the fixture of the multiple switchboard, cables and lines for new subscribers.

The directors regret that the results for the past year have not come up to their expectations, but bearing in mind the severe commercial depression which for a considerable portion of that year has prevailed in Monte Video and which has caused very many subscribers to curtail their expenses by relinquishing their subscriptions to the telephone exchanges, they cannot but deem it satisfactory to have maintained the profit at about £10,000. For these reasons it has not been deemed advisable to recommend any dividend on the ordinary shares. It is gratifying, however, to report that the latest advices from the manager are to the effect that a large number of subscribers who had left for a variety of reasons, have returned to the company.

In accordance with the articles of association, Mr. Peters retires from the board, but, being eligible, offers himself for re-election.

The auditors, Messrs. Gérard Van de Linde & Son, also retire, but offer themselves for re-election.

### The Metropolitan Electric Supply Company, Limited.

THE following is the report of the directors issued on Wednesday to the shareholders, and to be presented to the third ordinary general meeting next week:—

"1. Under the Electric Lighting Act it has been provided that the accounts of statutory supply companies shall be made up to the 31st December in each year, and that these accounts shall be presented to the Board of Trade not later than the 25th March in the year following.

"2. It will be remembered that last year the accounts were made up to the 30th September; in order, therefore, to comply with the above-mentioned statutory requirements, it is necessary to alter the period of the company's financial year to the end of December, and the date of the annual general meeting to the beginning of next year. The accounts for the 15 months ending the 31st December next will therefore be submitted to the meeting to be held early in 1891.

"3. The present meeting has been convened in accordance with article 71 of the company's articles of association, which provides that an ordinary meeting shall be held annually.

"4. The directors are pleased to have the opportunity of informing the shareholders that the company is making steady and substantial progress in its works, and that what promises to be a large and remunerative business is being built up.

"5. During the 14 months which have elapsed since the company obtained Parliamentary powers, upwards of 40 miles of electric light mains have been laid in pipes under the streets of the principal thoroughfares of the company's districts.

"6. Current is being supplied from four central stations, two of which, viz., Whitehall and Sardinia Street, are fully equipped, while the other two, viz., Rathbone Place and Manchester Square, are on the eve of completion.

"7. The company's area of supply has been enlarged by the addition of the important and valuable district of Paddington. The directors are giving careful consideration to the best means of supplying current in this district, and an advantageous site on which to erect a central station has already been acquired on favourable terms.

"8. While it is impossible, until the accounts have been made up and audited, to review the company's financial position in detail, the directors are of opinion that the prospects of the company are such as to warrant them in looking forward to a satisfactory dividend being earned during the ensuing year.

"9. In accordance with the articles of association, three of the directors, viz., Sir James Anderson, Mr. J. Spencer Balfour, M.P., and Sir George Elliott, Bart., M.P., retire by rotation, and, being eligible, offer themselves for re-election.

"10. The auditors, Messrs. Deloitte, Dever, Griffiths & Co. retire, and offer themselves for re-election.

### The Indo-European Telegraph Company, Limited.—

The board of this company has declared an interim dividend for the half-year ended the 30th June last, at the rate of 5 per cent. per annum.

**Electrical Engineering Corporation, Limited.**—Mr. Carl Von Buch, of Messrs. Foote and Von Buch, electrical engineers, 11, Queen Victoria Street, E.C., has joined the board.

**Messrs. Ruston, Procter & Co.**—This company has declared an interim dividend of 5s. per share.

## TRAFFIC RECEIPTS

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending October 24th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,742.

The Brazilian Submarine Telegraph Company, Limited. The traffic receipts for the week ending October 24th were £4,834.

THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.  
(Continued from page 505.)

There is a paradoxical experiment which we will try next week, that illustrates an important principle. If you take a tubular electro-magnet and put little pieces of iron into the ends of the iron tube that serves as core, and then magnetise it, the little pieces of iron will try to push themselves out. There is always a tendency to try and increase the completeness of the magnetic circuit; the circuit tends to re-arrange itself so as to make it easier for the magnetic lines to go round.

Here is another paradoxical experiment. I have here a bar electro-magnet, which we will connect to the wires that bring the exciting current. In front of it, and at a distance from one end of the iron core, is a small compass needle with a feather attached to it as a visible indicator, so that when we turn on the current the electro-magnet will act on the needle, and you will see the feather turn round. It is acting there at a certain distance. The magnetising force is mainly spent not to drive magnetism round a circuit of iron, but to force it through the air, flowing from one end of the iron core out into the air, passing by the compass needle, and streaming round again, invisible, into the other end of the iron core. It ought to increase the flow if we can in any way aid the magnetic lines to flow through the air. How can I aid this flow? By putting on something at the other end to help the magnetic lines to get back home. Here is a flat piece of iron. Putting it on here at the hinder end of the core ought to help the flow of magnetic lines. You see that the feather makes a rather larger excursion. Taking away the piece of iron diminishes the effect. So also in experiments on tractive power, it can be proved that the adding of a mass of iron at the far end of a straight electro-magnet greatly increases the pulling power at the end that you are working with; while, on the other hand, putting the same piece of iron on the front end as a pole-piece greatly diminishes the pull. Here, clamped to the table, is a bar electro-magnet excited by the current; and here is a small piece of iron attached to a spring balance, by means of which I can measure the pull required to detach it. With the current which I am employing, the pull is about 2½ lbs. I now place upon the front end of the core this block of wrought iron; it is itself strongly held on; but the pull which it itself exerts on the small piece of iron is small. Less than half a pound suffices to detach it. I now remove the iron block from the front end of the core, and place it upon the hinder end. And now I find that the force required to detach the small piece of iron from the front end is about 3½ lbs., instead of 2½ lbs. The front end exerts a bigger pull when there is a mass of iron attached to the hinder end. Why? The whole iron core, including its front end, becomes more highly magnetised, because there is now a better way for the magnetic lines to emerge at the other end and come round to this. In short, we have diminished

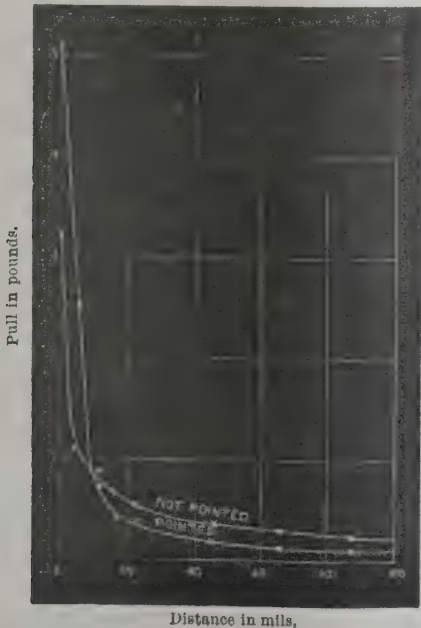

FIG. 35.—CONTRASTED EFFECT OF FLAT AND POINTED POLES.

the magnetic reluctance of the air part of the magnetic circuit, and the flow of magnetic lines in the whole magnetic circuit is thereby improved. So it was also when the mass of iron was placed across the front end of the core; but the magnetic lines streamed away backwards from its edges; and few were left in

front to act upon the small bit of iron. So the law of magnetic circuit action explains this anomalous behaviour. Facts like these have been well known for a long time to those who have studied electro-magnets. In Sturgeon's book there is a remark that bar magnets pull better if they are armed with a mass of iron at the distant end, though Sturgeon did not see what we now know to be the explanation of it. The device of fastening a mass of iron to one end of an electro-magnet in order to increase the magnetic power of the other end was patented by Siemens in 1862.

We are now in a position to understand the bearing of some curious and important researches made about forty years ago by Dr. Julius Dub, which, like a great many other good things, lie buried in the back volumes of Poggendorff's *Annalen*. Some account of them is also given in Dr. Dub's now obsolete book, entitled *Elektromagnetismus*.

The first of Dub's experiments to which I will refer relates to the difference in behaviour between electro-magnets with flat and those with pointed pole ends. He formed two cylindrical cores, each six inches long, from the same rod of soft iron, one inch in diameter. Either of these could be slipped into an appropriate magnetising coil. One of them had the end left flat, the other had its end pointed, or, rather, it was coned down until the flat end was left only ¼ inch in diameter, possessing therefore only one-fourth of the amount of contact surface which the other core possessed. As an armature there was used another piece of the same soft iron rod, 12 inches long. The pull of the electro-magnet on the armature at different distances was carefully measured, with the following results:—

Distance apart in inches.	Pull on flat pole (lbs.).	Pull on pointed pole (lbs.).
0	3.3	5.2
0.0055	1.1	1.8
0.0110	0.9	0.75
0.0165	0.71	0.50
0.022	0.60	0.42
0.044	0.38	0.20
0.088	0.19	0.09

These results are plotted out in the curves in fig. 35. It will be seen that in contact, and at very short distances, the reduced pole gave the greater pull. At about ten mils distance there was equality, but at all distances greater than ten mils the flat pole had the advantage. At small distances the concentration of magnetic lines gave, in accordance with the law of traction, the advantage to the reduced pole. But this advantage was, at the greater distances, more than outweighed by the fact that with the greater widths of air-gap the use of the pole with larger face reduced the magnetic reluctance of the gap and promoted a larger flow of magnetic lines into the end of the armature.

Dub's next experiments relate to the employment of polar extensions or pole-pieces attached to the core. These experiments are so curious, so unexpected, unless you know the reasons why, that I invite your especial attention to them. If an engineer had to make a firm joint between two pieces of metal, and he feared that a mere attachment of one to the other was not adequately strong, his first and most natural impulse is to enlarge the parts that come together—to give one as it were a broader footing against the other. And that is precisely what an engineer, if uninstructed in the true principles of magnetism, would do in order to make an electromagnet stick more tightly on to its armature. He would enlarge the ends of one or both. He would add pole pieces to give the armature a better foothold. Nothing, as you will see, could be more disastrous. Dub employed in these experiments a straight electro-magnet having a cylindrical soft iron core, 1 inch in diameter, 12 inches long; and as armature a piece of the same iron, 6 inches long. Both were flat ended. Then six pieces of soft iron were prepared of various sizes, to serve as pole pieces. They could be screwed on at will either to the end of the magnet core or to that of the armature. To distinguish them we will call them by the letters A, B, C, &c. Their dimensions were as follows, the inches being presumably Bavarian inches:—

Piece.	Diameter.	Length.
	inches.	inches.
A	2	1
B	1½	1½
C	1⅓	2
D	2	½
E	1½	1
F	1	2

Of the results obtained with these pieces we will select eight. They are those illustrated by the eight collected sketches in fig. 36. The pull required to detach was measured, also the attraction exerted at a certain distance apart. It will be noted that, in every case, putting on a pole piece to the end of the magnet diminished both the pull in contact and the attraction at a distance

\* Cantor Lecture. Delivered before the Society of Arts, January 27th, 1890.

it simply promoted leakage and dissipation of the magnetic lines. The worst case of all was that in which there were pole-pieces both on the magnet and on the armature. In the last three cases the pull was increased, but here the enlarged piece was attached to the armature, so that it helped those magnetic lines which came up into it to flow back laterally to the bottom end of the electro-magnet, while thus reducing the magnetic reluctance of the return path through the air, and so increasing the total number of magnetic lines, did not spread unduly those that issued up from the end of the core.

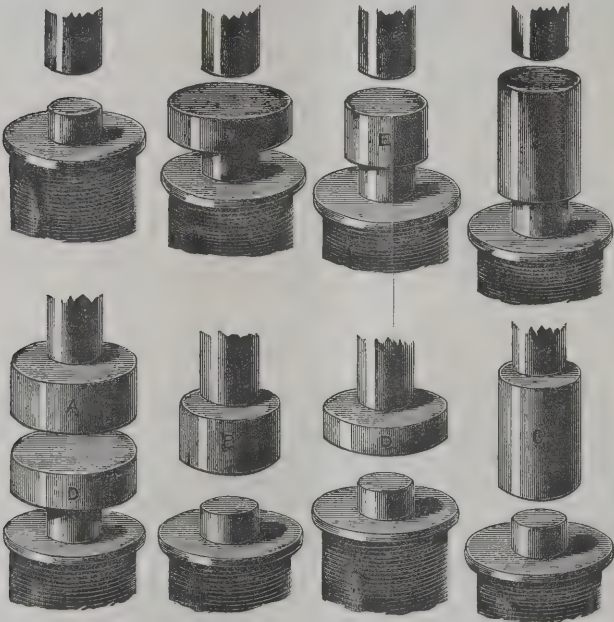

FIG. 36.—DUB'S EXPERIMENTS WITH POLE-PIECES.

The next of Dub's results relate to the effect of adding these pole-pieces to an electro-magnet 12 inches long, which was being employed, broadside-on, to deflect a distant compass needle (fig. 37).

In another set of experiments of the same order a permanent magnet of steel, having poles, *n*, *s*, was slung horizontally by a bifilar suspension, to give it a strong tendency to set in a particular direction. At a short distance laterally was fixed the same bar electro-magnet, and the same pole-pieces were again employed. The results of attaching the pole-pieces at the rear end are not very conclusive; they slightly increased the deflection. But in the absence of information as to the distance between the steel magnet and the electro-magnet, it is difficult to assign proper values to all the causes at work. The results were :—

D ... ..	8.8

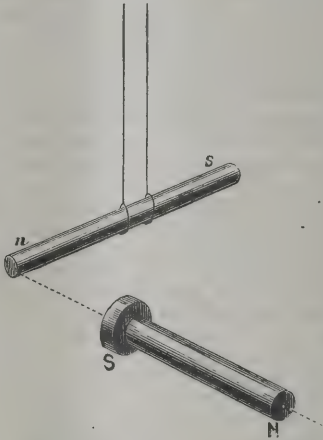

FIG. 38.—DEFLECTING A STEEL MAGNET HAVING BIFILAR SUSPENSION, POLE-PIECE ON NEAR END.

When, however, the pole-pieces were attached to the distant end of the electro-magnet, where their effect would undoubtedly be to promote the leakage of magnetic lines into the air at the front end without much affecting the distribution of those lines in the space in front of the pole, the action was more marked.

Still confining ourselves to straight electro-magnets, I now invite your attention to some experiments made in 1862 by the late Count Du Moncel as to the effect of adding a polar expansion to the iron core. He used as his core a small iron tube, the end of

which he could close up with an iron plug, and around which he placed an iron ring which fitted closely on to the pole. He used a special lever arrangement to measure the attraction exercised upon an armature distant in all cases one millimetre from the pole. The results were as follows :—

	Without ring on pole.	With ring on pole.
Tubular core alone ... ..	11	10
ditto with iron plug ... ..	17	14
Core provided with mass of iron at distant end	27	25
ditto ditto with iron plug ...	38	33

After hunting up these researches, it was extremely interesting to find that so important a fact had not escaped the observant eye of the original inventor of the electro-magnet. In Sturgeon's "Experimental Researches" (p. 113) there is a footnote, written apparently about the year 1832, which runs as follows—

"An electro-magnet of the above description, weighing three ounces, and furnished with one coil of wire, supported 14 lbs. The poles were afterwards made to expose a larger surface by welding to each end of the cylindric bar a square piece of good soft iron; with this alteration only the lifting power was reduced to about 5 lbs., although the magnet was annealed as much as possible."

We saw that this straight electro-magnet, whether used broad-side-on or end-on, could act on the compass needle at some distance from it, and deflect it. In those experiments there was no return-path for the magnetic lines that flowed through the iron core save that afforded by the surrounding air. The lines flowed round in wide-sweeping curves from one end to the other, as in fig. 26; the magnetic field being quite extensive. Now, what will happen if we provide a return path? Suppose I surround the electro-magnet with an iron tube of the same length as itself, the lines will flow along in one direction through the core, and will find an easy path back along the outside of the coil. Will the magnet thus jacketed pull more powerfully or less on that little suspended magnet? I should expect it to pull less powerfully, for if the magnetic lines have a good return path here through the iron tube, why should they force themselves in such a quantity to a distance through air in order to get home? No, they will naturally return short back from the end of the core into the tubular iron jacket. That is to say, the action at a distance ought to be diminished by putting on that iron tube outside. Here is the experiment set up. And you see that when I turn on the current my indicating needle is scarcely affected at all. The iron jacket causes that magnet to have much less action at a distance. Yet I have known people who actually proposed to use jacketed magnets of this sort in telegraph instruments, and in electric motors, on the ground that they give a bigger pull. You have seen that they produce less action at a distance across air, but there yet remains the question whether they give a bigger pull in contact? Yes, undoubtedly they do; because everything that is helping the magnetism to get round to the other end increases the goodness of the magnetic circuit, and therefore increases the total magnetic flux.

We will try this experiment upon another piece of apparatus, one which has been used for some years at the Finsbury Technical College. It consists of a straight electro-magnet set upright in a base-board, over which is erected a light gallows of wood. Across the frame of the gallows goes a winch, on the axle of which is a small pulley with a cord knotted to it. To the lower end of the cord is hung a common spring balance, from the hook of which depends a small horizontal disc of iron to act as an armature. By means of the winch I lower this disc down to the top of the electro-magnet. The current is turned on; the disc is attracted. On winding up the winch I increase the upward pull until the disc is detached. See, it required about 9 lbs. to pull it off. I now slip over the electro-magnet, without in any way attaching it, this loose jacket of iron—a tube, the upper end of which stands flush with the upper polar surface. Once more I lower the disc, and this time it attaches itself at its middle to the central pole, and at its edges to the tube. What force will now be required to detach it? The tube weighs about ½ lb., and it is not fixed at the bottom. Will 9½ lbs. suffice to lift the disc? By no means. My balance only measures up to 24 lbs., and even that pull will not suffice to detach the disc. I know of one case where the pull of the straight core was increased 16-fold by the mere addition of a good return-path of iron to complete the magnetic circuit. It is curious how often the use of a tubular jacket to an electro-magnet has been re-invented. It dates back to about 1850, and has been variously claimed for Romershausen, for Guillemin, and for Fabre. It is described in Davis's "Magnetism," published in Boston in 1855. About 16 years ago Mr. Faulkner, of Manchester, revived it, under the name of the *Altanda* electro-magnet. A discussion upon jacketed electro-magnets took place in 1876, at the Society of Telegraph Engineers; and in the same year, Prof. Graham Bell used the same form of electro-magnet in the receiver of the telephone which he exhibited at the Centennial Exhibition. But the jacketed form is not good for anything except increasing the tractive power. Jacketing an electro-magnet which already possesses a return circuit of iron is an absurdity. For this reason, the proposal made by one inventor to put iron tubes outside the coils of a horseshoe electro-magnet is one to be avoided.

We will take another paradox, which equally can be explained by the principle of the magnetic circuit. Suppose you take an iron tube as an interior core; suppose you cut a little piece off the end of it; a mere ring of the same size. Take that little piece and lay it down on the end. It will be struck with a certain amount of pull. It will pull off easily. Take that same round piece of iron, put it on edgewise, where it only touches one point of the circumference, and it will stick on a good deal tighter, because it is there in a position to increase the magnetic flow of the magnetic lines. By concentrating the flow of magnetic lines over a small surface of contact increases B at that point, and B<sup>2</sup>, integrated over the lesser area of the contact, gives a total bigger pull than is the case when the edge is touched all round against the edge of the tube.

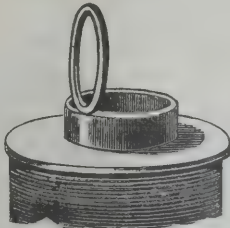

FIG. 40.—EXPERIMENT WITH TUBULAR CORE AND IRON RING.

Here is a still more curious experiment. I use a cylindrical electro-magnet set up on end, the core of which has at the top a flat circular polar surface about two inches in diameter. I now take a round disc of thin iron—ferrotype or tin-plate will answer quite well—which is a little smaller than the polar face. What will happen when this disc is laid down flat and centrally on the polar face? Of course you will say that it will stick tightly on. If it does so, the magnetic lines which come in through its under surface will pass through it and come out on its upper surface in large quantities. It is clear that they cannot all, or even any considerable proportion of them, emerge sideways through the edges of the thin disc, for there is not substance enough in the disc to carry so many magnetic lines. As a matter of fact, the magnetic lines do come through the disc, and emerge on its upper surface, making indeed a magnetic field over its upper surface that is nearly as intense as the magnetic field beneath its under surface. If the two magnetic fields were exactly of equal strength, the disc ought not to be attracted either way. Well, what is the fact? The fact, as you see now that the current has been turned on, is that the disc absolutely refuses to lie down on the top of the pole. If I hold it down with my finger, it actually bends itself up, and requires force to keep it down. I lift my finger and over it flies. It will go anywhere in its effort to better the magnetic circuit rather than lie flat on the top of the pole.

Next I invite your attention to some experiments, originally due to Von Kolke, published in the *Annalen* forty years ago, respecting the distribution of the magnetic lines where they emerge from the polar surface of an electro-magnet. I cannot enumerate them all, but will merely illustrate them by a single example. Here is a straight electro-magnet with a cylindrical, flat-ended core (fig. 41). In what way will the magnetic lines be distributed over at the end? Fig. 41 illustrates roughly the way in which, when

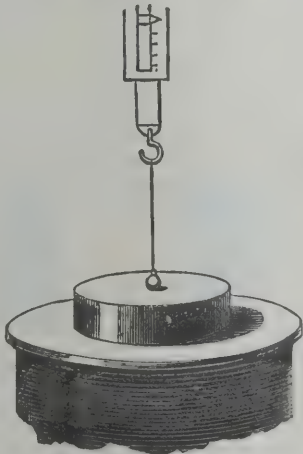

FIG. 41.—EXPLORING POLAR DISTRIBUTION WITH SMALL IRON BALL.

there is no return-path of iron, the magnetic lines leak through the air. The main leakage is through the ends, though there is some at the sides also. Now the question of the end-distribution we shall try by using a small bullet of iron, which will be placed at different points from the middle to the edge, a spring balance being employed to measure the force required to detach it. The pull at the edge is much stronger than at the middle, at least four or five times as great. There is a regular increase of pull from the middle to the edge. The magnetic lines, in trying to complete their own circuit, flow most numerous in that direction where

they can go furthest through iron on their journey. They leak out more strongly at all edges and corners of a polar surface. They do not flow out so strongly at the middle of the end surface, otherwise they would have to go through a larger air circuit to get back home. The iron is consequently more saturated round the edge than at the middle; therefore, with a very small magnetising force, there is a great disproportion between pull at the middle and that at the edges. With a very large magnetising force you do not get the same disproportion, because if the edge is already far saturated you cannot by applying higher magnetising power increase its magnetisation much, but you can still force more lines through the middle. The consequence is, if you plot out the results of a succession of experiments of the pull at different

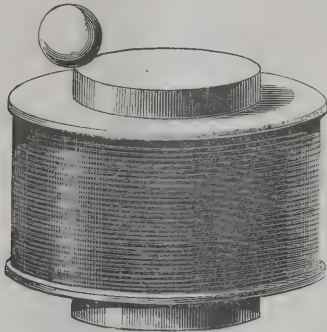

FIG. 42.—IRON BALL ATTRACTED TO EDGE OF POLAR FACE.

points, the curves obtained are, with larger magnetising forces more nearly straight than are those obtained with small magnetising forces. I have known cases where the pull at the edge was six or seven times as great as in the middle with a small magnetising power, but with larger power not more than two or three times as great, although, of course the pull all over was greater. You can easily observe this distribution by merely putting a polished iron ball upon the end of the electro-magnet, as in fig. 42. The ball at once rolls to the edge and will not stay at the middle. If I take a larger two-pole electro-magnet (like fig. 11) what will the case now be? Clearly the shortest path of the magnetic lines through the air is the path just across from the edge of one polar surface to the edge of the other between the poles. The lines are most dense in the region where they arch over in as short an arch as possible, and they will be less dense along the longer paths, which arch more widely over. Therefore, as there is a greater tendency to leak from the inner edge of one pole to the inner edge of the other, and less tendency to leak from the outer edge of one to the outer edge of the other, the biggest pull ought to be on the inner edges of the pole. We will now try it. On putting the iron ball anywhere on the pole it immediately rolls until it stands perpendicularly over the inner edge.

The magnetic behaviour of little iron balls is very curious. A small round piece of iron does not tend to move at all in the most powerful magnetic field if that magnetic field is uniform. All that a small ball of iron tends to do is to move from a place where the magnetic field is weak to a place where the magnetic field is strong. Upon that fact depends the construction of several important instruments, and also certain pieces of electro-magnetic mechanism.

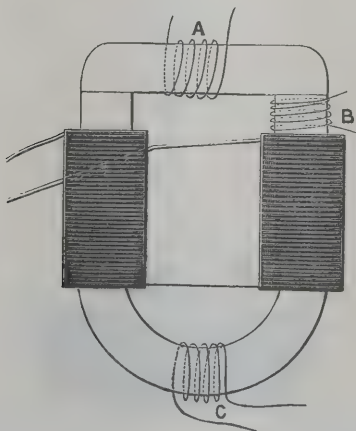

FIG. 43.—EXPERIMENT ON LEAKAGE OF ELECTRO-MAGNET.

In order to study this question of leakage, and the relation of leakage to pull, still more incisively, I devised some time ago a small experiment with which a group of my students at the Technical College have been diligently experimenting. Here (Fig. 43) is a horseshoe electromagnet. The core is of soft wrought iron, wound with a known number of turns of wire. It is provided with an armature. We have also wound on three little exploring coils, each consisting of five turns of wire only, one, c, right down at the bottom, on the bend; another, b, right round the pole, close up to the armature; and a third, a, around the

middle of the armature. The object of these is to ascertain how much of the magnetism which was created in the core by magnetising power of these coils ever got into the armature. If the armature is at a considerable distance away, there is naturally a great deal of leakage. The coil, c, around the bend at the bottom is to catch all the magnetic lines that go through the iron; the coil, b, at the poles is to catch all that have not leaked outside before the magnetism has crossed the joint; while the coil, a, right around the middle of the armature, catches all the lines that actually pass into the armature and pull at it. We measure by means of the ballistic galvanometer and these three exploring coils how much magnetism gets into the armature at different distances, and are able thus to determine the leakage and compare these amounts with the calculations made, and with the attractions at different distances. The amount of magnetism that gets into the armature does not go by a law of inverse squares, I can assure you, but by quite other laws. It goes by laws which can only be expressed as particular cases of the law of the magnetic circuit. The most important element of the calculations, indeed, in many cases is the amount of percentage of leakage that must be allowed for. Of the magnitude of this matter you will get a very good idea by the result of these experiments following.

The iron core is 13 millimetres in diameter, and the coil consists of 178 turns. The first swing of the galvanometer when the current was suddenly turned on or off measures the number of magnetic lines thereby sent through, or withdrawn from, the exploring coil that is at the time joined to the galvanometer. The currents used varied from 0·7 of an ampère to 5·7 ampères. Six sets of experiments were made with the armature at different distances. The numerical results are given below:—

I.—WITH WEAK CURRENT (0·7 AMPERES.)

	A	B	C
In contact ... ..	12,506	13,870	14,190
Armature distance. { 1 mm. ... ..	1,552	2,163	3,786
2 mm. ... ..	1,149	1,487	2,839
5 mm. ... ..	1,014	1,081	2,028
10 mm. ... ..	676	1,014	1,690
Removed ... ..	...	675	1,352

II.—STRONGER CURRENT (1·7 AMPERES.)

	A	B	C
In contact ... ..	18,240	19,590	20,283
Armature distance. { 1 mm. ... ..	2,570	3,381	5,408
2 mm. ... ..	2,366	2,839	5,073
5 mm. ... ..	1,352	2,299	5,949
10 mm. ... ..	811	1,352	3,381
Removed ... ..	...	1,38	3,041

III.—STILL STRONGER CURRENT (3·7 AMPERES.)

	A	B	C
In contact ... ..	20,940	22,280	22,960
Armature distance. { 1 mm. ... ..	5,610	7,568	11,831
2 mm. ... ..	4,597	6,722	9,802
5 mm. ... ..	2,569	3,245	7,436
10 mm. ... ..	1,149	2,704	7,088
Removed ... ..	—	2,306	6,427

IV.—STRONGEST CURRENT (5·7 AMPERES.)

	A	B	C
In contact ... ..	21,980	23,660	24,040
Armature distance. { 1 mm. ... ..	8,110	10,810	17,220
2 mm. ... ..	5,611	8,464	15,886
5 mm. ... ..	4,056	5,273	12,627
10 mm. ... ..	2,029	4,057	10,142
Removed ... ..	...	3,581	9,795

These numbers may be looked upon as a kind of numerical statement of the facts roughly depicted in figs. 31 to 34. The numbers themselves, so far as they relate to the measurements made (1) in contact, (2) with gaps of one millimetre breadth, are plotted out on fig. 44; there being three curves, a, b, and c, for the measurements made when the armature was in contact, and three others, a<sub>1</sub>, b<sub>1</sub>, c<sub>1</sub>, made at the one millimetre distance. A dotted line gives the plotting of the numbers for the coil c, with different currents, when the armature was removed.

(To be continued.)

## LEGAL.

**Chatenay v. The Brazilian Submarine Telegraph Company, Limited.**—(Before the Master of the Rolls and Lords Justices Lindley and Lopes).—This appeal from the judgment given in the *ELECTRICAL REVIEW* for February 28th, came on for hearing in the Appeal Court on Saturday last.

It was an application under the Companies Act to restore the name of the plaintiff on the register as the owner of 50 of the company's shares.

The plaintiff was a Swiss merchant residing in Rio Janeiro, in Brazil, and in 1880 he executed a power of attorney authorising his agent in London to buy and sell shares for him in England and in all other countries. In 1883 the shares in question, which stood upon the register in his name, were transferred to other persons at the instance of the plaintiff's agent. On the plaintiff discovering that this had been done, he claimed to have his name restored on the register as the owner of the shares, but the company refused to comply with his request, with the result that the present application was made. Mr. Justice Day held that the power of attorney, which was written in the Portuguese language, must be construed according to the English law, which required that the instrument should be supplemented by letters of instructions applicable to each transaction, which letters were not held by the plaintiff's agent in reference to the transaction in question. The company appealed.

Mr. Finlay, Q.C., and Mr. W. Graham appeared for the company, and Mr. H. D. Green, Q.C., and Mr. A. Young for the respondents.

Mr. FINLAY contended that reference must be made to the law of Brazil to ascertain the extent of the powers conferred by the plaintiff upon his agent, and in order to ascertain the intention of the parties. By the law of Brazil, the power of attorney conferred full authority upon the agent to deal with the shares without any letters of instruction being required.

Mr. H. D. GREEN submitted that the document, being intended to operate in England, must be supplemented by all that the English law required.

Their lordships held that the document being executed in Brazil, and being in the Portuguese language, the intention of the parties must be ascertained by competent translators and experts, but that the extent of the authority given by it must be determined by the law of England in the case of transactions in this country. This was a mere expansion of Mr. Justice Day's judgment, and, therefore, the appeal must be dismissed with costs.

**The Tharsis Sulphur and Copper Company v. La Societe Des Metaux.**—This case came before Mr. Justice Charles in the Queen's Bench Division on Saturday last. It was an action brought to recover the sum of £59,186, being damages for breach of contract to accept delivery of and pay for certain quantities of copper.

Mr. Gorell Barnes, Q.C., and Mr. Houghton appeared for the plaintiffs, and Mr. Kennedy and Mr. H. Tindall Atkinson for the defendants.

This case was one of several which arose out of the breakdown of the French combination known as the "Copper Ring" last year. Most of the questions, however, which arose in it had been decided in previous actions brought in the English Courts against the same defendants. The plaintiffs were an English company, incorporated under the Companies' Act, and the defendants were a body of persons incorporated in France. On April 20th, 1888, a contract was made between the parties by the exchange in London of duplicate parts thereof, one of which had been executed by the plaintiffs in Glasgow, and the other by the defendants in Paris. By the contract the defendants agreed to purchase at prices therein named all the refined copper manufactured by the plaintiffs during three years commencing January 1st, 1888. In March, 1889, the defendants went into liquidation. By the terms of this contract, the defendants elected domicile in this country. The amount now claimed by the plaintiffs was the deficiency arising upon re-sales of the copper, of which the defendants had not taken delivery under the contract. The defendants pleaded that, the contract having been executed by them in Paris, was a French contract, and subject to French law, and consequently was illegal and void, inasmuch as it was contrary to Article 419 of the Code Pénal, which, it was alleged, rendered a combination such as this, to affect the price of goods, illegal. Further, that by the French law of liquidation, the plaintiffs could not rescind the contract and recover damages, but could only exercise a right of election between rescinding the contract (without damages) and delivering the copper, and proving in the liquidation for the price. The plaintiffs admitted that the last statement was a correct one of the French law on the subject, but denied the alleged illegality, and contended that the contract was an English contract, and was, therefore, unaffected by the French law. In the case of "Antony Gibbs and Son v. La Société des Metaux" (6, the *Times* L. R., 393), the Court of Appeal, upon similar facts, held that the right to sue on an English contract was not affected by the French law of liquidation, and in "Cape Copper Company v. Comptoir d'Escompte and La Société des Metaux" (6, the *Times* L. R., 454), Mr. Justice Day held that similar contracts were English contracts, and that the rights of the parties were, therefore, to be determined according to English law.

Mr. JUSTICE CHARLES said that, although some of the facts as to the execution of the contract in this case were different to those in the cases referred to above, yet he had come to the conclusion that the contract was an English contract, and that his duty was to follow the judgment of Mr. Justice Day in the other cases, which proceeded on the ground that the parties themselves had agreed that the contract should be subject to English law, and that it was to be performed (and, until the liquidation, had been performed), within the jurisdiction of the English Courts.

Judgment was accordingly given for the plaintiffs with costs; the damages to be agreed between the parties, or, in case of difference, to be settled by the judge.

## NEW PATENTS—1890.

15792. "Improvements in incandescent electric lamps, and leading-in wires therefore." B. J. B. MILLS. (Communicated by T. A. Edison, United States.) Dated October 6.

15819. "Improvements in electric dynamos, electric motors, transformers of electric currents, and induction coils." J. JOHNSTONE. Dated October 7.

16054. "Improvements in electric batteries." H. G. C. SERRIN. Dated October 9.

16055. "Improvements in electric batteries." H. G. C. SERRIN. Dated October 9.

16057. "Improvements in pillars and electroliers or pendants for electric lamps." R. B. EVERED and T. RUDLING. Dated October 9.

16064. "Improvements in electrical secondary batteries." J. K. PUMPELLY and F. BUTTERWORTH. Dated October 10. (Complete.)

16110. "Improvements in the distribution of electricity." T. PARKER, J. H. WOODWARD and E. S. G. REES. Dated October 10.

16136. "Improvements in coin-freed apparatus for obtaining a current of electricity for producing electric light, or for other purposes." H. J. DOWSING and H. S. PRICE. Dated October 11.

16156. "Improving mains for carrying currents of electric matter." J. JOHNSTONE. Dated October 11.

16222. "Improvements in lanterns or lamps for arc electric lights, and in posts or columns therefor." A. L. SHEPARD. Dated October 11.

16223. "Improvements in the parts of electric meters connecting the movement of the solenoid with the calculating train." H. BURROW. Dated October 11.

## ABSTRACTS

## OF PUBLISHED SPECIFICATIONS 1889.

12563. "Improvements in electrical ships' logs, or means for ascertaining by electricity the speed of ships." R. M. LOWNE. Dated August 8. 11d. Claims:—1. A rotator with affixed towing line operating an electrical contact apparatus on board ship, or at any convenient distance therefrom, substantially as shown and described and for the purpose stated. 2. A rotator with affixed towing line operating an electrical contact apparatus on board ship, or at any convenient distance therefrom, in combination with conductors, battery, indicator or indicators, substantially as shown and described and for the purpose stated. 3. The combination of rotator, affixed towing line, battery, contact apparatus, conductor, cable, indicator or indicators on board ship, substantially as shown and described and for the purpose stated. 4. The combination of combined rotator, battery, and contact apparatus, with conductor, cable, and an indicator or indicators on board ship, substantially as shown and described and for the purpose stated. 5. The method of insulating movable conductors substantially as shown and described and for the purpose stated.

14011. "Improvements in switches for opening and closing electrical circuits." A. L. SHEPARD. Dated September 5. 8d. Relates to a switch which ensures the circuit being always either fully open or completely closed, and secures a perfect contact between the fixed and movable portions which serve to convey the current, thereby preventing the formation of arcs at the point of such contact, and consequent damage to or destruction of the apparatus. 6 claims.

14377. "Process of and apparatus for maintaining uniform current in electric lighting circuits." J. M. BRADFORD. Dated September 12. 1s. 1d. In this invention the strength of a variation in the line current is not a necessary factor in securing energy of regulating action; the regulating devices act with an accumulative effect, or in opposition with a differential effect, according to the duration of a variation of the line current, and changes in the line current can be anticipated or prevented, instead of being reduced after they are developed. 10 claims.

14464. "Improvements in electricity meters." E. BATAULT. Dated February 15. (Under International Convention.) 8d. Relates to apparatus or electricity meters based on the principle

which consists in measuring, at regular intervals of time, the length of the tangent of the angle of deviation of the hand of a galvanometer placed in the circuit of the current to be measured, and in registering the sum of these tangents. 4 claims.

14485. "Improvements in magneto-electric bells or generators in connection with telephonic call apparatus." A. GREENWOOD. Dated September 14. 8d. This invention is for the purpose of improving upon switching arrangements by automatically switching the extension bell or bells out of circuit when the magneto generator is in motion, and by automatically switching the extension bell or bells into circuit when the magneto generator is at rest. To accomplish this the inventor utilises the motion made by the generator shaft of a magneto bell in a horizontal and lateral direction; this motion is used in ordinary magneto bells for the purpose of shunting the armature circuit when the armature or generator is at rest, and is made by means of a spiral spring arrangement known as the cut-out. The inventor employs this motion for the purpose of switching off and on the extension bell or bells automatically, by causing the generator shaft, handle and gearing, to break the connection between armature and line or earth (made by a contact spring) when the armature, gearing and shaft are at rest; and by causing the armature to be connected through the said contact spring to line or earth when the armature, gearing and shaft are in motion. 1 claim.

14590. "Improvements in electric bells." H. GROVES and J. H. STEWART. Dated September 16. 8d. The inventors employ but one magnet bobbin, which they erect vertically on the base of the instrument; it has two pole pieces, one above and the other below. The armature they make of T-form, the cross piece or head (which is the armature properly so called) is vertical, and its ends are in close proximity to the pole pieces of the magnet. The armature is attached to and carried by a spring blade fixed to the horizontal stem of the T-piece. 4 claims.

16586. "Improvements in electric switches." T. MARCHER and F. ERNECKE. Dated October 21. 8d. The object of the invention is to prevent any possibility of a middle position of a circuit closer. 3 claims.

17060. "Improvements in electrical furnaces and their manipulation." T. PARKER. Dated October 29. 8d. Instead of using movable anodes of metal or carbon, the inventor uses blocks of carbon fixed in the walls of the furnace opposite to each other, and set at suitable distances apart in the interior of the furnace wherein it is intended to treat the materials at the high temperature of the electric arc or incandescence due to the current. These blocks of carbon are fixed in metal conductors, which may be kept cool by a circulation of water within themselves. The blocks of carbon are arranged with holes through their centres, so that a rod of metal or small rod of carbon may be used to establish the circuit through the furnace. 6 claims.

## CORRESPONDENCE.

### The Lane-Fox Patents.

Permit me to make some remarks upon the article on my patents which has appeared in your last issue. The ELECTRICAL REVIEW has earned the reputation of being both a fair and a well informed journal, and it is with regret, therefore, that I have now to find fault with the inaccurate and superficial manner in which you are now dealing with my "pretensions," as you term them.

Before commenting on the more technical side of your article, I desire to reply to the accusation (for it is nothing less) which you make against myself and my "associates" of not fighting fair. Nobody could deprecate more than we do any unnecessary harassing of innocent, that is to say, unintentional, infringers of my patents. Our desire throughout has been to select the right people—the "foemen worthy of our steel," as you so poetically express it—and failing more conciliatory methods of obtaining our just rights, to fight them. When you insinuate that the opposite has been our policy, you convict yourselves either of a deliberate perversion of the true history of our course of action since my settlement with the Brush Company last December, or else—as I prefer to believe—of a misapprehension founded upon ignorance of the facts. If I am right in this latter construction, I am sure you will gladly allow me to correct you by assuring you, what you can easily prove for yourselves, that it is only quite recently, and after exhausting all the more direct methods of drawing out our real opponents, that we were reluctantly obliged to force their hands by

"having a go" at their customers. In so acting we have, after all, only tardily taken up the gauntlet thrown down to us by a certain organisation started by our opponents (and whose manifesto you have already made public in one or more of your August issues), which made a direct appeal to the "consuming" public to co-operate with them against us. In the case of the well-known electric light supply company, against whom we first had occasion to direct our fire, our attack was evidently far too direct for their liking; for instead of taking up our challenge at once, they have put us off with what I can only characterise as an alternation of bluster and prevarication, the motive of which we now assume to have been to gain time for the concoction of an elaborate defence. However all this may turn out, we may certainly claim freedom from the reproach of cowardice.

But although rather glad than otherwise of this opportunity to put yourselves and your readers on the right clue to our motives in the somewhat uncongenial procedures to which you have referred, I do not wish to take up any more of your space with this part of your attack on myself and my friends. I confidently leave our fuller justification to the future.

Now as to my inventions themselves. In complaining of the *simplicity* of my system, you are according to it the highest praise which I could desire for it. To say nothing of the familiar story of Columbus and the egg, a powerful judgment was recently delivered on a patent case in the Supreme Court of the United States, in the course of which this very quality of simplicity (in conjunction, of course, with efficiency and utility), far from being adduced in disparagement of the patent's validity, was extolled as the sign-manual of the highest merit which an invention could possess. There are some people, it is true, who are under the impression that a patent, to be of any value, should in some way or other transcend the laws of nature, if not actually conjure into operation some new or mythical force. I should be sorry, however, to attribute such puerile reasoning either to yourselves or to the generality of your readers.

Next I desire to deprecate the assumption which I note in your article—and which may encourage others to assume—that certain combinations for electric lighting purposes now quite familiar, were always matters of common knowledge, or at any rate that they were so at the date of my chief patent (1878). No one who had experienced a fraction of my difficulties, between then and 1881, of convincing even the scientific world of the theoretical, to say nothing of the practical feasibility of my proposed system, would fall into this mistake. I do not wish to quote in this connection certain eminent electricians now living, until I have their express authority for so doing—an authority which I believe will not be denied to me if and when I may deem it necessary to request it. But I feel at liberty at least to mention that the late Sir William Siemens and also Mr. William Spottiswoode, then President of the Royal Society, both expressed their strong opinion at a meeting of the Society held in 1879, that the distribution of the electric light, then beginning for the first time to be talked of, was from theoretical considerations a thing not to be hoped for. (It will be remembered by many of your readers that the telephone and the phonograph, when first heard of, were similarly ridiculed by contemporary electricians of high standing.)

To illustrate the kind of treatment which the subject of distribution received at that period, it may be mentioned that Edison's first patent for electric lighting (the application for which is dated a few weeks later than my own), which was for nothing more than the operation of incandescent lamps in *series*, with a special regulating device for shunting the current across the lamps whenever the latter became too brilliant, was loudly proclaimed as a grand and fundamental discovery of the means of distributing electric light. My plan of maintaining a constant *potential* in electric mains, notwithstanding any variations in the number of lamps in action, was certainly, so far as I have been

able by careful and protracted investigation to ascertain, quite unthought of at that date, and, in spite of all my efforts, my patent attracted but little attention. As to the modern incandescent lamp, specially adapted for the system which I claim to have been my invention—a lamp, that is to say, in which the luminous surface, resistance, and candle-power are adjusted to suit a fixed potential of the mains—it would have had no *raison d'être* at that date, or until my system began to be applied; consequently this system, although *simple* enough truly, cannot be fairly summarised (as you seem to suggest that it should be, and as other objectors have also suggested), as merely an *obvious* combination of already well-known elements. Even if this were the case, by the way, the patent itself would not on that account necessarily be invalidated.

From the above considerations it will be sufficiently evident that both of the two instances of alleged anticipation which you quote are quite fallacious. In the case of Farmer's "demonstration," primary batteries were used in connection with platinum wires or strips; but neither was my combination employed, nor even one of its most essential elements, viz., the modern incandescent lamp, constructed on the principles described in my specification; nor was there any hint of the importance of maintaining a constant potential difference or the means by which such could be obtained. On this point the note on Sir David Salomons's reference to the proposed use of primary batteries for incandescent lighting, which you publish on page 496 of the same issue under the heading of "Electric Light and Potential Difference," is singularly opportune. The other instance, namely Breguet's experiment at Paris in 1877, may be disposed of by a similar process of analysis, for although of course the use of secondary batteries gives a fictitious appearance of analogy, the fundamental idea of multiple arc distribution of electric light at a constant potential is wholly absent.

Briefly as to the present position of my "troublesome claim." The only claim for which I am now endeavouring to obtain a substantial (but financially moderate) recognition, is for my combination, as more fully described in the specification of letters patent No. 3,988,\*\* of 1878, of a system of incandescent lamp distribution in multiple arc, at a constant potential, with secondary batteries as reservoirs of electrical energy.

One last word. If by your reference to the Brush Company's attitude towards my "pretensions," you mean to imply that they have not recognised the validity of my patents—the only sense in which I can see any force in your remarks on this point—I cannot imagine who your informant may have been, but must assure you that you are entirely mistaken. The differences between us were quite of another kind.

St. G. Lane-Fox.

P.S.—October 28th—I have just received a letter from General Webber, in which he says: "In writing to the ELECTRICAL REVIEW you have my authority to state that when I was acting as managing director and engineer of the Anglo-American Brush Corporation the validity of your distribution patent was held to be as good as that of any which had actually not been contested in the courts of law, and that at that time the Anglo-American Brush Corporation had every intention of bringing the same to an issue."

#### Telephone Switchboards.

I have read with interest the description of the improved switchboard and switching system, invented by Mr. D. Sinclair, and beg of you to allow me space for a few questions thereon, viz.:—

1. Is the system intended for metallic return, or for only single metallic circuits?

2. How are the connections of the telephone, transmitter, magnets, bell, &c., formed in the circuit of the plug, indicator and jack?

3. Have the indicators one or two coils or cores?

I admire the simplicity of the arrangement, as shown,

which is an important consideration in telephony, and should commend itself to those engineers who are responsible for the planning and fitting up of exchanges in the future.

Z.

#### Accumulator Management.

In reply to the question of "B. B." as to how much soda should be added to one gallon of the ordinary dilute acid electrolyte, I think I may say that in many cases one ounce would be a good proportion, although sometimes more may be used with advantage if the plates are badly sulphated. Carbonate of soda (ordinary washing soda) must be used, and on no account commercial sulphate of soda.

W. J. S. Barber Starkey.

October 25th, 1890.

#### Accumulator Explosions.

Referring to the reported explosion on Lord Poulett's yacht, I well remember a similar accident on board the *Giovanni Bausan*, an Italian warship, which was fitted with electric light under my superintendence, by Messrs. Armstrong, Mitchell & Co., in 1885.

The cells in this case were contained in teak boxes with a small aperture plugged with a cane stopper in the lid, and the explosion occurred owing to one of these plugs being withdrawn, and a lighted candle applied in order to see whether the cell was giving off gas during the process of charging. Only one cell went off, but the teak case was split into numerous fragments, the plates were bent, and the acid splashed about. No one was injured, but the noise was exceedingly loud, and there was a remarkably vivid flame.

Considering that oxygen and hydrogen gases, mixed in the right proportion, form, weight for weight, the most energetic explosive known to science, the matter is perhaps not so very remarkable as some may think.

A. A. Campbell Swinton.

October 24th, 1890.

An accurate account of an explosion similar to that on Earl Poulett's yacht may be of interest at this moment.

This explosion took place last week on board the Clyde training ship *Empress*, where a set of 26 teak cased cells have been placed as part of the lighting plant. The cells are of the ordinary yacht pattern, viz., sealed with the exception of the small vent hole on top and are placed on an open rack in the engine room, where they are quite free from damp, and as there is a large porthole open behind the rack the ventilation is all that could be desired, in fact the draught is so strong that it is with difficulty a naked light can be kept burning near the cells.

The lid had been removed from one of the cells that the hydrometer might be seen, and it was when the engineer lit a match to look into this cell the explosion took place, destroying one cell on each side of the open one. No explosion seems to have occurred in the open cell, as the hydrometer was not injured and although the outer plates were bent and the lead lining driven in this may have been caused by the fragments of the burst cells striking the outside.

Judging from the condition of the two damaged cells the force of the explosion must have been considerable as the upper half of each cell was not merely burst open, but the woodwork was shattered into small pieces and the brass terminal screws which are cast into the lead were pulled right out.

The dynamo was running when the explosion took place and the cells were gassing freely having been charging about 26 hours (the cells being new). The fact that only two cells exploded may be explained by the draught carrying the gas away from the cells, and

not along the row and the vertical supports of the rack, partly isolating these three cells from the others.

Fortunately no one was near the battery at the time except the engineer, and he escaped with a bruise caused by a flying piece of wood.

Mr. Edmunds's suggestion in your last issue cannot be applied to this case as the cells were under cover and there was certainly no damp about any of the connections.

The cause of the accident seems clear, and the remedy is very simple. It is just as easy to use an incandescent lamp as a match or a candle, and in the interests of the electrical industry the danger of naked lights should be impressed upon those who have dealings with this type of accumulator.

J. Hunter.

October 27th, 1890.

The following account, *apropos* of explosions in secondary batteries, may possibly interest readers of this journal.

About five years ago, whilst charging a batch of E.P.S. 17 S teak cells (lead lined), I was engaged in tightening up the nuts on connecting strips, and in so doing accidentally short circuited one of the cells with the metal spanner I was using. Immediately there was a loud report, the teak lid (firmly screwed down and cemented) flew into fragments, and one side of the box was split from top to bottom, but the lead lining fortunately remaining intact, no leakage of solution occurred; the sections moreover, were undisturbed, as proved by the fact of this very cell having outlived all the rest of the battery, and expiring from genuine decay but a few days ago.

The cause of the explosion was, to my mind, to be easily accounted for in this wise. The lid possessing a vent hole (for the escape of gases), situated near one of the terminals of the cell, contributed a direct supply of the gases for any sparking which would ensue in the event of a short circuit being temporarily effected between the conductors.

On Lord Poulett's yacht the battery appears to have been to a certain extent enclosed, thus rendering free escape of gas in a heavy, wet atmosphere, more unlikely to occur than if the weather had been fine at the time, consequently the explosive mixture readily found its way below deck *via* the cable channels, thus establishing a direct connection between battery and source of ignition.

I fail to see how the general public can be expected to support and favour the new illuminant, if instructed by scientific (?) paragraphs, as provided by some of our daily papers.

Lyndhurst.

#### The Sweating System.

In your issue of October 10th a correspondent signing himself "An Electrical Trades Unionist," makes an onslaught of a most ferocious character upon what he has chosen to call the "Sweater." By the tenor of his letter I am inclined to think that this gentleman would have better borne out his character had he signed his effusion "An Electrical Trades Monopolist." His object seems to be to stamp out "the little man." to improve him off the face of the earth, so that the whole industry may be in the hands of enormous Syndicates, otherwise Limited Liability Companies. Personally, I should say that this letter to which I have referred was a "bogus" letter and not written by a unionist at all, but by a capitalist, or an emissary of such. My experience is that the small man pays his workmen quite as well as the big one, and in many instances better. I have paid linemen 1s. per hour. How many large firms pay their men more than half that sum? The breakdowns to which "E.T.U." alludes, do no harm to the industry at all. They simply open the owner's eyes, and he hands his work over to someone else in the future. Breakdowns, Sir, are more due to the ini-

quitous state of the law, which permits installations to be superintended and managed by grooms, gardeners, odd job men and "master Johns," in place of having a competent man. And I can tell you, Sir, that the big firms of our friend "E.T.U.'s" fancy are more to be blamed than anyone for this very thing. The small man is generally a practical man who works himself. The work done by a big firm is generally "bossed" by some kid-glove pupil who cannot make a common solder joint. I can give chapter and verse for what I say, and every man who reads these lines, if he has had any experience at all, can vouch for the truth of it. Why, Sir, one of our largest firms at one of our great exhibitions placed the management of the installation in the hands of one of these automatons, and the initial performance of this representative of "a first-class firm" was to switch on with the voltmeter in series with the main circuit. This sweating charge is humbug, Sir, when applied to the small tradesman. It is the big firms who piece-work the men who do all this, and I should say that no one knows this better than Electrical Trades Unionist himself.

A Small Manufacturer.

October 26th, 1890.

#### The Invention of the Telephone.

We are all familiar with the earlier telephonic experiments of Reis, which are given in the *Jahres Bericht des Physikalischen Vereins*, of Frankfort, for 1860-1861, and which are regarded as the precursor of the telephone of Graham Bell. Prof. Bell read a paper on the subject before the Society of Telegraph Engineers on 31st October, 1877, and at this lecture I called attention to a still earlier description of a telephone by Charles Bourseul, which is to be found in the second edition of the Comte Theodore du Moncel's *Exposé des applications de l'électricité*, published in Paris in 1857, Vol. 3, page 110. Du Moncel does not give any reference to the original paper, but in the *Didaskalia*, a weekly paper published at Frankfort-on-Maine, No. 232, dated 28th September, 1854, there is an interesting account of his invention, which I do not remember to have seen printed in England. I am indebted to Messrs. Siemens Bros. & Co. for making the translation, which I enclose, and if not hitherto published, it will, I am sure, interest your readers, as his description of the principle of the telephone is almost as clear as if it were written at the present date. If he had only put his ideas to the test of experiment, we should have had the telephone in 1854.

It would be interesting to find the original source from which Count Du Moncel derived his account of Bourseul's telephone.

Latimer Clark.

October 28th, 1890.

[Full particulars of everything mentioned by Mr. Latimer Clark have from time to time been published in the REVIEW. Bourseul and the *Didaskalia* were quite familiar names in our pages of years ago, through the contributions to the subject of telephony so frequently published from the pen of Major W. C. Barney.—EDS. ELEC. REV.]

#### Semaphore Telegraphs.

In your next issue, will you please oblige me by saying where I could find a sketch of the old English semaphore telegraph used up to the introduction of electric telegraphs.

If you could give a sketch, I should be greatly obliged.

J. H. Tattershall.

Postal Telegraphs, Rochdale.

[We regret we have been unable to find the information you require; perhaps some one of our readers may be able to furnish the desired reference.—EDS. ELEC. REV.]

THE ELECTRO-DEPOSITION OF  
COPPER.

IN our correspondence columns we publish a letter from Mr. W. Stepney Rawson which necessitates a few remarks on our part. We have to thank Mr. Rawson for his letter. If he only appreciated our anxiety to place before our readers any information we can obtain which would help them to arrive at a correct judgment on the question he would have made his letter longer, and we should have been glad to find room for any facts and figures it might have contained. Our correspondent writes apparently in some haste and with some warmth, but we must make allowances for one who, having only just returned from abroad, seems scarcely at home with his subject.

Mr. Rawson has selected eight points from our recent articles on the electro-deposition of copper, in order to demonstrate how utterly in the wrong we have placed ourselves, and he doubtless thinks that any reply we can make will be of little avail; that, however, we are content to leave to the unbiassed judgment of our readers. It will be noticed that our calculations and deductions are held to be practically ridiculous, whatever that may mean, although the writer takes care not to give any figures to show that they are theoretically incorrect; but we will let that pass, and assume, for the sake of argument, that Mr. Rawson's knowledge of the electro-deposition of copper is far greater than that of any of the eminent scientists and authorities we have credited with the responsibility of certain data. Let us also take it that the figure quoted on the authority of Mr. Sprague, viz., "that the maximum allowable current for obtaining proper deposition is 18 ampères per square foot of surface of the electrodes," is more than double of what is possible in ordinary commercial depositing, and reduce it, say, to 7 ampères; and, according to Mr. Rawson's assertion, we will admit that in the Elmore process the current density is three times this amount. The difference between this result and the figure taken by us for our cal-

culatation is so small that we fail to see the force of his contention, especially as we clearly stated that probably by the use of the burnisher a somewhat heavier current might be employed per square foot of surface.

Mr. Rawson is equally at fault on the horse-power question, for he has not taken into consideration our article of the 24th ult., in which we compared a German establishment working 144 hours per week with the Elmore factory on Dr. Hopkinson's estimate of 161 hours.

It is not for us to reconcile the figures of cost on p. 479 with anything whatever; they are not of our compiling, but are given by Fontaine as the actual expenses in three works. It is for our correspondent to show that the Elmore process does not involve an expenditure of more than one-third of the amounts there given as the experience of years. The power, it will be observed, in this table varies from 20 to 50 per cent. of the total cost; which of these percentages does Mr. Rawson deem most applicable to the Elmore case? Let him read more carefully what Fontaine says regarding the cost of fuel; the French authority quotes only 5s. per ton, and yet asserts that motive power costs in Birmingham 125 francs per ton of copper. Mr. Rawson, therefore, instead of being surprised that we dared to estimate the expenses of electrical deposition on an assumption opposed to experience, should have set himself to work to show how the figures we gave as the results of actual practice can so differ from those which he presumably possesses but fails to produce when wanted.

We have shown, by an exhaustive comparison with the Mouchel copper, why there is no reason to anticipate any extraordinary demand for high conductivity Elmore copper wire; Mr. Rawson simply asserts his belief that the company can show a handsome profit in this department; indeed, his communication is entirely made up of assertions and opinions, but not one fact does he bring forward in support of them.

We beg to assure Mr. Rawson that if he will again carefully peruse our comments, he will fail utterly to

find any reference reflecting on the quality of the articles. With regard to the last paragraph of Mr. Rawson's letter we may say that we have no intention of discussing with him the question of high principles, and we venture to think his letter would have been improved by the omission of the sarcasm. As he has undoubtedly misunderstood the purport of some of our remarks perhaps we ought to make them clear to him. We examined the patents and the reports on them as we examined other points. We found the general exaggeration to be common to them too. The value of the patents was the question. Messrs. Woodhouse and Rawson should be aware that if an invention is successful there are always people ready to "steal the ideas of the inventor," as our correspondent puts it. The object of a patent is to prevent their doing so, and the value of a patent depends upon the extent to which it does prevent their doing so. Any flaw which may exist is taken advantage of in defending a patent suit; and the possibility of the existence of such flaws is a most material factor in considering the value of a patent. The only surprise to us is, that with Messrs. Woodhouse and Rawson's practical experience in this particular line, they should have failed to give due importance to this consideration. Mr. Rawson's trained mind has enabled him to observe in our remarks on this point a sinister suggestion which they were not intended to contain; nevertheless, we imagine that the same high principles which influenced his firm to promote company after company on the strength of the Elmore patents, will not be entirely absent from the minds of future inventors who would also like to participate in the benefits to be derived from electro-deposition.

We need not remind our correspondent that it is through no fault of ours that we have failed to see the process; will he now, as we are unable to do so, publicly give, in a table similar to that to which he refers on page 479, the various details which go to make up a total cost of but £5 per ton for Elmore copper?

A contemporary last week published an article from the pen of Dr. Gore, in which we consider there is much to support our previous contentions, and the writer concludes thus:—"In consequence of the numerous circumstances which affect the cost, an approximately satisfactory estimate of the total amount of capital required to be invested in establishing an electrolytic refinery to deposit a given amount of copper daily, can only be arrived at by means of a knowledge of all the essential particulars in the given case."

As Mr. Rawson is perfectly conversant with "all the essential particulars" we require, let him place, then, before us the items mentioned in Dr. Gore's *Recapitulation*.

---

## THE CITY AND SOUTH LONDON RAILWAY.

---

THE inauguration of this enterprise on Tuesday afternoon was a great success in almost every respect, and we must congratulate the City and South London Railway

Company and its officials not only on a splendid engineering achievement, but also on the excellent social arrangements during the opening ceremony. Punctually at noon, their Royal Highnesses the Prince of Wales and the Duke of Clarence and Avondale arrived at the City terminus, where they were received by the chairman of the company, Mr. C. G. Mott. After descending the hydraulic lift in its handsomely furnished cage, the Prince of Wales proceeded to turn a small switch with a gold key, giving thereby the signal for the current to be turned into the conducting mains. This act was witnessed by the Lord Chancellor, the Lord Mayor and the Sheriffs; Mr. J. H. Greathead (engineer); Mr. T. C. Jenkin (manager); Mr. H. H. M. Smith (secretary); Mr. C. E. Spagnoletti (consulting electrician); General Hutchinson and Major Cardew (Board of Trade); and Sir John Fowler (consulting engineer).

Ten minutes later, after examining the electric locomotives and carriages, the Prince and some forty gentlemen boarded the train, which consisted of two saloon cars. The engine was in charge of Mr. W. Mather, M.P., and Dr. Edward Hopkinson, and it was driven by Mr. G. A. Grindle, accompanied by Dr. John Hopkinson. Nine minutes later the Oval Station,  $2\frac{1}{2}$  miles distant, was reached, the intermediate stations—Borough, Elephant and Castle, and Kennington—being passed without a halt. After examining the Oval Station and its equipments, the party re-entered the train and proceeded to the South-West terminus at Stockwell. An excellent luncheon was then served in a tastefully-decorated Indian pavilion, where about 300 invited guests sat down. Mr. C. G. Mott presided, having on his right the Prince of Wales and on his left the Duke of Clarence and Avondale. Besides the gentlemen previously mentioned there were present:—Sir F. Abel, Sir F. Bramwell, Sir B. Baker, Sir H. Roscoe, Sir Douglas Galton, Sir E. Reed, M.P.; Mr. Causton, M.P.; Sir John Monckton, Sir H. Tyler, Mr. Henry Tate, and other notabilities. The electrical fraternity, not directly connected with this enterprise, was represented by Sir David Salomons, Dr. Silvanus P. Thompson, Mr. W. Raworth, Mr. A. P. Trotter, Mr. A. Reckenzaun, and Mr. F. Wynne.

After luncheon, the Prince of Wales, when replying to the usual second loyal toast, proposed "Success to the City and South London Railway" in most appropriate and happy terms. The Chairman acknowledged the compliments of His Royal Highness and stated that the design of the railway was that of Mr. Greathead, who had carried it out under his own superintendence, aided by the company's consulting engineers Sir John Fowler and Sir Benjamin Baker.

Running, as it did, under the streets, without interfering with property on the surface, the undertaking promised to be remunerative. With regard to the motive power, it was originally intended to be worked by an endless cable, but the directors had decided that this plan was not the best for their purpose, and consequently adopted electricity, on the method suggested by Messrs. Mather and Platt, worked out by Dr. Edward Hopkinson, in conjunction with his brother Dr. John Hopkinson.

As we are giving a complete description of its technical details in another column, we shall only dwell upon the general impressions formed both at a private view and during the opening celebration. We were particularly struck with the novelty and originality of construction which was apparent on every side, and this is the best testimony to the genius of the originators of this extraordinary enterprise. Every praise is due, not merely to the engineers and architects for designing a great work which combines utility and comfort, but also to the pluck of the directors and shareholders who had unlimited faith in the abilities of the technical staff.

Although the method of working a train electrically is not new, the scale upon which electric propulsion is carried out is, in this case, quite unprecedented; it is the largest undertaking of its kind in the world, and we believe it will be the forerunner of even greater things in this domain. The City and South London Railway Company has the advantage of knowing beforehand what its traction expenses will be, for the enterprising contractors, Messrs. Mather and Platt, guarantee that for the first two years it shall not exceed  $3\frac{1}{2}$ d. per train mile. On the Metropolitan Underground Railway, where steam locomotives (the product of 50 years' inventions and improvements) are used, the haulage cost is 10d. per mile, with a train capacity of 450 passengers. But these require much larger tunnels, and have to maintain a permanent way twice as heavy to accommodate their steam and smoke emitting locomotives.

Messrs. Mather and Platt have carefully calculated the probable expenditure of energy, and based their estimate upon well-known facts. Out of every 100 units of power developed by the boilers, 75 will be given out in electricity by the dynamos at the generating station; the average loss in the conductor will be at most another 5 per cent., rising from nothing at the central station to 10 per cent. at the extreme end of the line. Leakage, with the system of insulation adopted, will be almost *nil*. It is claimed that the motors give an efficiency of 90 per cent., and, since there is no gearing, the armatures being placed directly upon the driving axles, there should be a total estimated efficiency of 64 per cent.; if, in practice, the efficiency should not reach this high percentage there need be no alarm, considering the fact that the stationary boilers can be fed by burning coal of a quality which is not much more than half the price of best Welsh coal necessary in steam locomotives.

Accidents do happen, even on the oldest and best regulated railways. That the City and South London Railway is not exempt from this law was demonstrated on Tuesday afternoon. After luncheon at 3.30, a large party proceeded to the Stockwell Station platform, to be conveyed to the City as a *finale* to the day's programme. They waited until after 4 o'clock, but no train came in sight, and then the chairman announced that through some accident no more trains would be run that afternoon, and the guests thereupon dispersed to return by any of the existing conveyances on the surface roads. Too much importance must not, however,

be attached to this incident, for the initial proceedings are necessarily incomplete, and smooth working will follow with experience.

It is claimed that this railway has a great advantage over others in the way of safety to passengers. In the event of a train breaking down, the current will be cut off from the section, and it cannot be run into by a train following. The passengers can get out and walk to the next station, which in no case exceeds a distance of one-third of a mile.

The safety appliances on the line, as on the trains, leave nothing to be desired, and altogether the whole scheme deserves the admiration and encouragement of all.

---

#### Storage Batteries.

IN letters written by Mr. H. W. Miller, Engineer to the Kensington and Knightsbridge Electric Lighting Company, and Prof. A. B. W. Kennedy, Engineer to the Westminster Electric Supply Company, with reference to the Crompton-Howell storage accumulators, testimony is given as to the efficiency of the same, as the result of four years' working. Although there appears to be satisfactory evidence that the cells are doing excellent work, a few more definite figures would have been advisable. Mr. Miller, for instance, states that in his opinion "an average renewal of six to seven per cent. of the positive plates is enough." Why could not the actual renewals have been stated; were they actually greater than six to seven per cent., and if so, why? The efficiency obtained in practice is stated to be 85 per cent., a good result. Prof. Kennedy makes no remarks on depreciation, except that after 11 months' use nothing in the way of repairs had been done, a rather valueless statement. The battery appears to stand a heavy current being drawn from it without injury, a current of 250 ampères for half an hour having been taken on an emergency, the nominal capacity of the whole being 500 ampère hours. In view of the trouble so often experienced in the management of accumulators, it is satisfactory to find really good results obtained.

---

#### The French Elmore Company.

THE directors of the French Elmore Company have issued a circular to their shareholders announcing the appointment of Mons. Secretan as manager, and the issue of £50,000 debentures to the parent company, to provide the additional working capital which becomes necessary by reason of Mons. Secretan's belief in the process and the greater developments which may, in consequence, be expected. We can only characterise the circular as an elaborate puff with no solid substance in it. We have already given our advice to the shareholders. As this circular has been widely published, it may not be out of place to caution those who are not shareholders against being misled into believing so on the faith of any statements whatever short of accomplished facts.

## FRAUDULENT AND DOCTORED TELEGRAMS.

THE trial and conviction at the Central Criminal Court last Saturday week of an individual vaguely described as a commission agent, but who, more correctly speaking, should be called a telegraph clerk, and who was recently in the service of the Government, provides a fitting sequel to a series of fraudulent operations, which had for their object the plundering, by a system of deliberate swindling, of those apparently indispensable "professional" gentlemen who both on the racecourse and in town carry on the sporting business of "book-making."

For the professional racing man, whether "booker" or "backer," we have no particular feeling of sympathy or admiration, and though his praises have been sung very frequently in public, we suspect that the burthen of such adulatory lays have almost invariably been inspired, if not directly at least indirectly, by something approaching a "vested interest" in the ramifications of his quasi-equine profession. The threadbare argument of the almost romantic love of Englishmen for horses is one which has often been used to account for the mushroom-like growth of our racecourses; the amazing increase in the number and value of the races run, and the extraordinary prices given for thoroughbred stock, to say nothing of the fancy sums necessary for the propitiation of the "favourite jockeys" of the present day. However charming and soothing such sophistry may be, it does not offer a substantial explanation of our national extravagance on this peculiarly British subject, and the few apologists who argued the consequent improvement of the English thoroughbred as likely to be worth the price paid for it, have now retired into the region of utter darkness. There is one thing pretty certain, and that is this, that the "professional sportsman" has not got many high-fangled notions as to the sentimental or romantic; least of all in horse lore; it is plainly "win, tie, or wrangle," with him. The money is the sport and the spoil; the love of the horse once so desperately pleaded is merely a means to an end. Remind the average racing man of the classics of the horse; attempt to draw his impressionable soul into the history; more or less mythological, of Abaster, Aethon, Arion, Bayard, Borak, Rosinante, Xanthos, Sleipnir, or even such comparatively modern and material equine worthies as Bucephalus, Copenhagen and Black Bess. With the exception of perhaps the latter, he will know nothing of them; and to throw a light on his darkness he will probably ask what race they ran in, what weights they carried, and who trained them.

It was not the love of the horse which led the young man, Henry Ives, to the plotting and planning of an ingenious, yet artful and unprincipled scheme for the systematic swindling of the betting man, Pratt. Ives's plan, which we shall describe, was one which necessitated the aid of a confederate or confederates in the Central Telegraph Office; and, though it had been planned and resorted to before by a clerk not now in the telegraph service, and who cannot be found by the police, yet, sad to say, there were those who were willing to run the risk of detection and disgrace for the prospect of gaining a few pounds criminally and dishonestly. We will suppose a race as being set for decision at two o'clock. Henry Ives handed in a telegram addressed to "Jackson, High Street, Sunderland," at about a quarter to two. The address on the telegram was a bogus one, as was also the text, but it enabled the message form, which was timed 15 minutes or so before the advertised time of the race to reach the hands of the confederate, who was probably engaged at or near what is known as the Sunderland circuit. Here it was detained until the result of the race was known, then the address and the text, which had been lightly written, were erased, and a new and correct address having been substituted, the text was altered to a request to back so and so (the actual winner) for so many pounds; the message was then put rapidly into circulation, and delivered to the addressee, a betting

man. Ives had the authority of another betting man, named Miller, to use his name; Pratt, the recipient of the telegram, would, unless suspicions were aroused, imagine the telegram, from the early time it bore, to be a genuine one from his "client," Miller, and would book the amount to his credit accordingly.

It is quite possible that this clever, though unprincipled scheme, has been managed successfully before; but how often, of course, will never be known. It is probable that the large sums which were being put on in the name of Miller, and the unvarying success attending their outlay, aroused the suspicions of Pratt.

The jury had no difficulty in finding a verdict, and the plea usually put forward on such occasions in extenuation of guilt was once more forthcoming.

Henry Ives, like many others in his unfortunate and disgraceful position, advanced the time-worn excuse of being the dupe of others, who were older.

It may be the business of legal gentlemen, when all other excuses fail, to put forward the plea of "the dupe" in defence of their clients, but such generalities ought not to stand in the way of the punishment of the swindler and the thief.

The fact that sentence was deferred indicates that there may be some effort made to get Ives to say who has duped him; but anxious though most people are to see justice tempered with mercy to those who yield to sudden and overwhelming temptation, the circumstances of the case under notice suggest that there was neither sudden temptation nor temporary failure of moral rectitude, but rather that the whole matter was the outcome of a cunningly contrived, and ingeniously carried out, system for subverting the working of the telegraphic system to the nefarious ends of unprincipled and lawless men.

The Postal Telegraph Service derives a large revenue from the professional racing man, and, indeed, in this respect, our Government presents a strange anomaly, for with one service it caters and canvasses for the custom of racing men by extending telegraph communication to every conceivable place where racing of any importance is carried on; and with another institution, namely, the police, it gloriously upholds the State enactment that betting is illegal, and in the newspapers we may read that 10,000 messages were despatched on Derby Day from Epsom, or from Doncaster on the St. Leger Day (and what were they if they were not betting messages?), and in the next column find that the police have made a most successful raid on betting men, and that the magistrates have imposed heavy fines. Doubtless, with the elimination of the bookmaker, the interest in racing would become languid and tame, and if any excuse can be made for retaining him, it may be found that in the present condition and routine of society he is, as Robertson, in his comedy of "Ours," has said of matrimony—"a necessary evil, which at present we are unable to do without."

Betting, as carried on at the present time, seems to be an ever-growing practice of at least doubtful respectability, and, possibly, is able to boast as a business that it is not over-stocked, even in these days of limited trade and unlimited labour. The racing man's so-called love of the horse is the offspring of mercenary practices, and may be gauged by the volcanic explosion of appalling language which follows the defeat of the "beloved" steed, to whose chance of "getting home" he had entrusted some portion of his ill-gotten wealth. His anguish at such times may possibly partake of the classic, though this cannot be said of his love of the racehorse, or, indeed, of his language.

At all events, it must be admitted that he is entitled to the same measure of fair play, consideration, and protection at the hands of the telegraph service as any other person making use of its lines and *employés*, and it may be that Henry Ives, in durance vile, will have plenty of time to think of the squandered years and lost opportunities of his young life, and make resolves for a better future, or he may prefer to plot and plan some other ingenious combination of intelligence and cunning which will hereafter still further advance him on the road to ruin.

A SYNTHETIC STUDY OF DYNAMO  
MACHINES.

(Continued from page 356.)

IX.—THE HEATING OF MACHINES (*continued*).

THE temperature which an armature will attain in running depends upon the heat generated due to the three causes already mentioned, on the extent and character of the surface from which the heat is radiated, and on the velocity at which the surface is moving. Generally speaking, the exterior surface of the armature is smooth, but the periphery velocity varies from 3,000 feet per minute in direct current machines to 6,000, or even 8,000 feet per minute in alternators.

As may be imagined, it is difficult, if not impossible, to foretell precisely the extent to which the motion will be effective in dissipating heat, though for ordinary calculations it is assumed that a surface velocity of 3,000 feet per minute is equivalent to adding about one-half to the radiating surface. This, in other words, means that if the temperature of an armature at rest were raised 30° with the normal current, the temperature rise for a velocity of 3,000 feet per minute would be, neglecting hysteresis, only 20°.

For stationary coils wound with double cotton-covered wire, and varnished on the exterior, the equation connecting the rise of temperature with the radiating surface, and the power dissipated is approximately

$$C^{\circ} = \frac{W \ 330}{S}$$

where  $C^{\circ}$  is the rise in degrees Centigrade,  $W$  the rate at which energy is dissipated in watts, and  $S$  the area of the radiating surface in square centimetres. If the coils are wound on an armature and have a surface velocity of 3,000 feet per minute, the effect being equivalent to increasing the radiating surface, we have as approximately expressing the relation

$$C^{\circ} = \frac{W \ 220}{S}$$

There is a considerable amount of uncertainty as regards the latter formula, since the part which the surface speed plays in dissipating the heat depends entirely on the construction of the machine. In most armatures wound on the Gramme principle, for instance, the wire in the interior of the core presents a broken surface, which is manifestly more effective in getting rid of the heat than a smooth surface. Again, the spider arms are very often twisted to send a draft through the interior, or spaces are left at intervals in the core, through which the air is propelled by centrifugal force. In drum armatures, a space is sometimes left between the spindle bush and the central opening in the discs. But this space would have little value as far as dissipating heat is concerned, were it not that by twisted vanes or other means a draft is forced through the opening, and without experiment it is difficult to determine the effect a current of air created in this way will produce. The surface velocity makes a great difference to the capacity for dissipating heat, even if the surface is smooth, and there is no forced draft. Mr. Rehniewski considers that the heat which can be dissipated by an armature for a given rise of temperature above the atmosphere is nearly proportional to the peripheral velocity, in which case, taking the effect due to 3,000 feet per minute as indicated by the difference in the coefficients of the two equations, we have the rise in temperature represented by

$$C^{\circ} = \frac{W \ 330}{S \ v \cdot 0005}$$

where  $v$  is the surface velocity in feet per minute. In accordance with this assumption, the value of the surface for heat dissipation is 1.5 times greater when running at 3,000 feet per minute than when at rest,

while at a velocity of 6,000 feet it has three times the value. The writer has, however, been unable to test the truth of this supposition, and it is probably best to assume, in the absence of experiment, that the equation holds good only to 3,000 feet per minute, at which velocity plenty of experiments have been made. After this speed is reached, it is possible the proportionality may fall off somewhat; but if the surface is calculated as for 3,000 feet, the machine, at a higher speed, will have the advantage of running cooler.

Of course, the rise in temperature above given relates only to the exposed surfaces of the coils. In the case of stationary close-fitting magnet coils, the temperature next the sheet iron core on which they are wound is higher than at the external surface, but experiments to determine the difference of temperature between the inside and the outside have not been made so far. This difference of temperature may be expressed as the thermal pressure required to send the current of heat through successive layers of cotton-covered copper wire and insulating materials composing the coil, the flow taking place partly from layer to layer through bad conductors, and partly round and round the coiled wire. Though in estimating the cooling surface it is usual to neglect the flanged ends of the cores and the surface next the magnet, counting only the area of the exposed wire, there is undoubtedly some flow of heat towards the interior of the magnets and towards the end flanges, so that a little uncertainty exists regarding the exact area which ought to be regarded as cooling surface. Accordingly the formula, when applied to large coils, may give a greater rise of temperature than will be indicated on test, while applied to small coils the rise it gives may be somewhat less. It is very usual, when coils stand vertically, to make the cores somewhat larger than the magnets, thus leaving a space all round through which flows upwards by convection a continuous current of air. This reduces the difference of temperature between the top and bottom layers of wire, and if it were possible to wind the coils on a skeleton frame, so that half the heat could be carried off in this way, the difference between the temperature of the hottest wire then in the middle of the coil thickness, and the coolest then on both surfaces, would be reduced to about a half of its previous amount. There are, however, many practical objections to this, and in the absence of further experiment, we must content ourselves with keeping the surface temperature down to the limit of 75° C. already given, knowing that if the coils do not exceed  $2\frac{1}{2}$  to 3 inches in thickness, there is incurred, with the ordinary windings in use, no danger of overheating due to the greater temperature of the bottom layers. Accordingly, for a machine designed to work in an atmosphere of 40° C., the rise of temperature being fixed at 30°, a radiating surface of 11 square centimetres per watt, as indicated by the formula, would be allowed.

As regards armatures, the same reasoning applies. We argue that if the temperature of the surface does not exceed the limit given, no danger is to be apprehended from the greater temperature inside. In calculating the amount of radiating surface to be allowed, the heating due to hysteresis must, of course, be taken into account, as well as that due to the copper resistance of the conductors. For an armature having a peripheral speed of 3,000 feet per minute, and running in an atmosphere of 40° C., the rise of temperature being then 30°, the formula shows that about 7.4 square centimetres per watt are required for radiation, and this is the usual allowance, in practice, for a rise of 30°. If the rise is to be less, a correspondingly greater surface must be allowed. In cylinder machines, both the interior and exterior surfaces are counted as of equal value, the draft of air through the interior making up for the greater heat generated inside relatively to the amount of surface. In drum machines, the exterior surface is taken along with such proportion of the ends as may be considered of value for radiation.

Sometimes the rising of the surface temperature of an armature after the machine has stopped has been attributed to "accumulation of heat," an expression not

very apt in its application to the circumstances. In a long run, the armature must get to a temperature such that the loss of heat is exactly equal to the amount generated, though the time it requires to attain this temperature varies much according to the size and design of the machine. There is, in the proper sense, no accumulation after this point is reached, the rise of temperature after stopping being due to the fact that the capacity for dissipating heat is greatly reduced by the stoppage, that the flow of heat is therefore checked, and that the difference between the temperatures of the inside and outside are consequently diminished, the outside gradually getting hotter, until equilibrium between flow and temperature is established. The immediate effect of stopping is, therefore, to raise the temperature of the surface to something above its running temperature, but something under the temperature of the interior.

In designing machines, the field magnet coils are always made as short as the specified temperature limit will permit, but as regards the armature, conditions other than those having reference to heating may frequently operate to keep the temperature rise small. Generally, machines running at ordinary speeds, attain a temperature approaching the limits given, while running at slow speeds, high efficiency being maintained, the rise in temperature is much less. This means that the conductors in the latter case may have to be made so large to obtain high efficiency, that the temperature rise is considerably under the limit allowable.

If the heat generated in the armature winding, per unit of exposed surface, is to be constant, the current carried must vary as  $d^2$  where  $d$  is the diameter of the conductor. The heat generated by hysteresis having to be got rid of, modifies in practice the application of this rule, as do also other conditions referred to in preceding paragraphs. To show how the currents and sizes of conductors are related in modern machines, the following table is given from the results of practice, the armatures being in all cases Gramme wound.

Ampères.		Size of wire.	No. of layers.
5.0	...	·048" diam. single	... 4
7.5	...	·062" " "	... 3
10.0	...	·075" " "	... 3
20.0	...	·090" " "	... 2
22.5	...	·075" " double	... 2
25.0	...	·065" " triple	... 3
32.5	...	·080" " double	... 2
37.5	...	·126" " single	... 1
40.0	...	·090" " double	... 2
50.0	...	·109" " "	... 2
50.0	...	·148" " single	... 1
60.0	...	·180" " "	... 1
75.0	...	·203" " "	... 1
90.0	...	·238" " "	... 1

It remains to be mentioned that the current density per square centimetre section in the magnet winding of ordinary machines comes out about half the current density in the armature.

(To be continued.)

### M. E. MARES'S ELECTRICAL ENERGY METER.\*

THIS apparatus belongs to the class of watt-hour meters with a periodic discontinuous integration. Fig. 1 enables us to easily understand the principle of its working. It comprises, like all indicators of this class, an apparatus for measuring the power, an apparatus for measuring the time, and a system for integrating the power in relation to the time. The measuring apparatus consists of two fixed bobbins with vertical axes mounted in the general circuit of distribution and a movable bobbin of fine wire placed in derivation at the terminals of the canalisation, the distribution being performed with a potential to all intents constant. The movable

bobbin is influenced from above by the united action of the two fixed bobbins, and the force brought to bear upon it is at each moment equal to the product of the intensity of the current which passes through the fixed bobbins by the intensity of the current passing through the movable bobbin, *i.e.*, to the power,  $E I$ , supplied to the circuit, in virtue of the well-known principle of the watt-meter. This movable bobbin is suspended at the extremity of a horizontal lever, A B, the fulcrum of which is at *b*. Along this lever a carriage moves freely, its weight having been previously determined, and this moves the lever whenever its momentum in relation to the axis, *b*, attains a value equal to the momentum of the electro-dynamic force exercised between the bobbins in relation to the same axis. This carriage moves horizontally, changing its position on the lever, A B, by means of a wheel, M N, toothed on the inner edge of its rim and making one revolution in four minutes, and an inner wheel, O, bearing a number of teeth exactly equal to half that on the wheel, M N. Under these conditions we show kinematically that the point, *m*, describes a straight

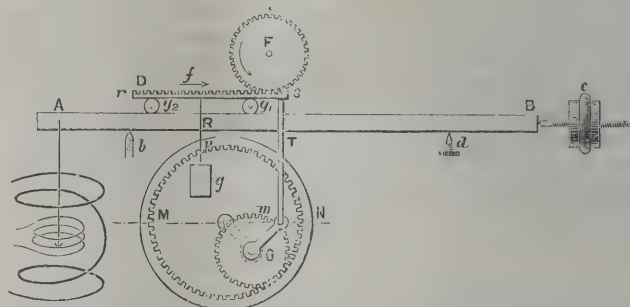

FIG. 1.—PRINCIPLE OF WORKING M. MARES'S METER.

line, which is really the diameter, M N. This horizontal movement to and fro is transmitted to the carriage by the rod, T, which is fixed to it. The position of this carriage is so arranged that its course begins, starting from the extreme left, at the moment when its centre of gravity is exactly over the point, *b*. At this instant, the momentum of the weight is nil, and that of the electro-dynamic force of the bobbins preponderates. The carriage is drawn along from left to right rolling along the lever, A B. On its upper surface is a little rack which turns the first wheel, F, of the integrating dial of the meter in the opposite direction to the hands of a watch until the momentum of the weight in relation to the axis, *b*, exceeds that of the electro-dynamic force in relation to the same axis. The lever then moves at the same time as the carriage, the rack ceases to be in contact with the wheel, F, and its movement is stopped. We can understand that, during the movement, the wheel, F, has turned at an angle proportionate to the path described by the carriage on the lever during the whole of the period that the electro-dynamic action exceeded the force exerted by the weight of the tray; *i.e.*, at an angle proportionate to the power expended by the circuit at the moment when the movement of the lever, A B, is produced. The length of the path described by the tray is arranged so that its maximum displacement will counteract or even overpower the electro-dynamic action corresponding to the maximum power of which the machine is capable.

In order to prevent the hands of the meter from going back during the return movement of the carriage, when the rack would turn the wheel, F, in the opposite direction, the current passing through the movable bobbin of fine wire is cut off during the half period occupied by the return of the carriage to its original position. The momentum of the electro-dynamic action being nil, the lever, A, B, remains at rest on its knife edge, *d*, and keeps the rack away from the wheel, F, during the whole of the period occupied by the return of the carriage. The same thing occurs

\* *L'Electricien*.

periodically every four minutes ; we can easily see that the sum of the angles described by the wheel, F, represents, by a quantity that is almost constant, the electrical energy supplied to the circuit during this period. This constant may easily be made to correspond with the unit, or one of its decimal multiples, by changing

according to M. Marès's instructions by M. Déjardin. The clockwork movement is kept up by the current itself, and the winding up is effected during the half period of two minutes during which the current is cut off in the fine wire bobbin. The winding up is performed by sending in each half revolution five succes-

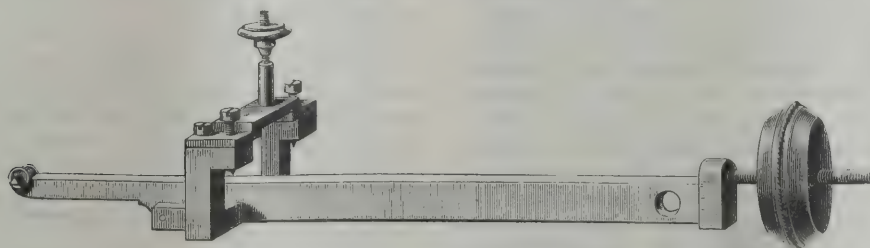

FIG. 4.

the total weight of the carriage, which can be effected with the greatest facility by placing regulating weights, previously accurately determined, in the little bucket, *g*, suspended at the centre of gravity of the carriage. Figs. 2, 3, 4 and 5 show different views of the meter, the principle of working of which we have just described, the mechanism having been constructed

sive currents into the winding electro-magnet (figs. 2 and 3), by means of five friction contacts suitably placed on the principal wheel.

Each of these five currents winds the system up one tooth, and as during a complete period the spring unwinds to the extent of five teeth, it follows that the tension always remains to all intents the same, a condi-

tion which is essentially favourable to the regularity of the clockwork movement, regulated in this case by a conical pendulum, with the object of avoiding all vibration and shaking, the conical pendulum maintaining, by its very principle of action, a movement that is always uniform. This conical pendulum also serves to bring the meter to a level when it is installed, and also when it is put in action.

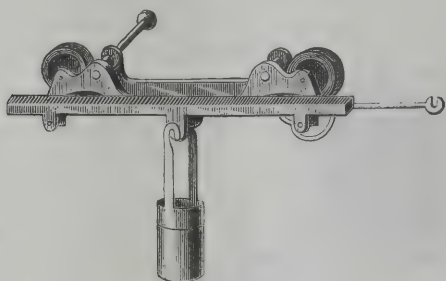

FIG. 5.

An electro-magnet that can be hooked on to the conical pendulum, and which is shown at the left of fig. 2, and at the right of fig. 3, enables the meter to be started at will after each stoppage.

Without dwelling upon the numerous details of construction, which have been most carefully studied both by the inventor and the constructor, we will merely remark that M. Marès's invention constitutes an absolute apparatus in which only those forces are introduced whose values are accurately known. As in the case of Mr. Walker's meter, described in a preceding number, and those which we shall hereafter describe, we will refrain from expressing any opinion on the practical value, if any, of these instruments until the experiments to which they are all to be subjected at the Municipal Electrical Works of the *Halles Centrales* are concluded.

## THE COPENHAGEN CENTRAL STATION.

[FROM A CORRESPONDENT.]

THE Copenhagen central electric light station, concerning the tenders for which a serious misunderstanding arose a short time ago, is to be erected by Messrs. Siemens and Halske for the simultaneous supply of 14,000 glow lamps. The *Elektrotechnische Zeitschrift* states that the work of erection will be commenced early in the spring, so that the station may be completed and ready to start lighting by the beginning of next winter. A site has already been chosen in the Gothesgade, which is situated in the centre of the town, so that the most remote point of distribution will only be 1,300 yards distant. The method of distribution will be the three wire system, which will be so arranged that the loss in E.M.F. between the station and the principal distributing points will be 28 volts, and from the latter to the lamps, 3 volts. The lamps will be of the 110-volt type, and the terminal pressure of the dynamos will therefore have to be 251 volts. The mains will consist of the well-known Siemens armoured cables. The generating station will contain seven tubular boilers of 235 square metres of heating surface, and three compound steam engines which will be coupled direct to six dynamos, each engine driving two machines. The total capacity of the dynamos, which will be of the internal pole type and connected two in series, will be 611 kilowatts.

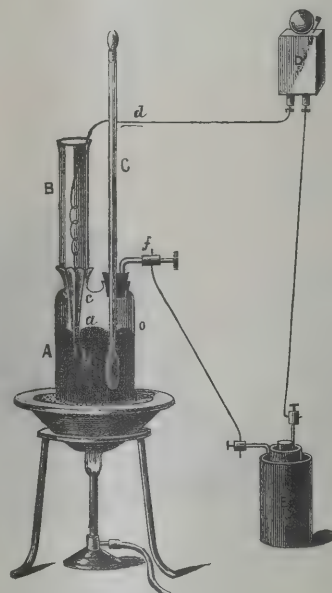

In order to avoid the running in the daytime of any dynamo or dynamos at less than full load, there is to be installed a battery of 272 Tudor accumulators having a discharge capacity of 250 ampères. Future extensions in the output of the station will be effected by increasing the number of accumulators, and for this purpose a four-storeyed building will be erected adjoining the station and capable of containing sufficient

cells to supply 14,000 lamps. In case of a further enlargement being necessary, it is proposed to erect accumulator stations in the suburbs where the cells would be charged direct from dynamos of a higher tension than those to be at first installed.

## A NEW ELECTRICAL APPARATUS FOR DETERMINING MELTING POINTS.

THE apparatus shown in the accompanying sketch is due to the ingenuity of A. C. Christomanos, who gives an elaborate description of it in the *Berichte der Deutschen Chemischen Gesellschaft*. He claims that by means of it a more correct determination of the melting point of substances may be ensured.

The essential features of this apparatus is as follows: The cylindrical vessel, A, which is 12 cm. in height and 6 cm. in diameter, is heated on a sand bath or in an air bath, and is provided with two apertures; a thermometer, C, and a platinum wire, f, pass through a cork fitting into one of the apertures, whilst the other, c, is conical and fluted, and serves for the reception of a drawn out test tube, B. The vessel, A, is filled with pure mercury to such a depth that the end, b, of the test tube is about 2 cm. below the surface, a o, of the metal.

The substance is introduced in a melted condition into the end, b, of the drawn out test tube, so that it forms a layer of from 0.5 to 1.5 cm. in length, and when it has completely solidified again the test tube is placed in position, and the space, a c, immediately above the substance filled with mercury, into which dips the platinum wire, d.

On applying heat, the mercury in A is uniformly heated throughout its whole mass, so that the thermometer and the substance are always at the same temperature; the moment the substance melts the two mercury columns come in contact, the circuit is completed, the bell, D, rings, and the temperature is noted.

**Fire Caused by an Electric Wire.**—The *St. James's Gazette* had on Monday a sensational paragraph as to a fire caused by an electric light wire in the Grand Café, Boulevard des Capucines, Paris, on Saturday night. Shortly after 9 o'clock the lights went out, and a strong odour of burning India-rubber was perceptible. The woodwork in the cellar began to burn, and in a very short time flames appeared from the windows. Before the current was turned off and the fire extinguished considerable damage had been done.

## TELE-PHOTOGRAPHY.

By HENRY SUTTON.

UNDER various names the problem of transmitting optical images by aid of the telegraph wire has at different times had attention drawn to it.

In putting forward something new in this direction, I will begin by inventing a new name, and propose calling the subject Telephany, and the electro-optic instrument the Telephane.

The art of telephony is simple compared with that of telephany. In the former we deal with a consecutive series of waves of varying rate and length, and it is the consecutive character of sound waves that lends itself so admirably to electrical translation.

In telephany we are met, at the outset, with a great preliminary difficulty, having to deal with a surface or plane in which the effect appealing to the brain must be observed in all the varying character at one and the same time.

The problem stands thus : a means has to be devised whereby the varying effects on a plane surface are translated into consecutive series of electrical currents, and by means of the consecutive series of currents reconstruct, so to speak, a copy of the original surface ; that is, we have to take an optical image, seen as a *surface*, translate it into a *line* of consecutive varying electrical currents, and by means of these produce an effect as a *surface*, having the characteristics of the original image.

We have here two images as surfaces having no time value, and a series of electrical currents having a time value, yet these opposing characteristics are to be presented to the brain as a momentary impression.

Before showing how this apparently impossible problem may be handled, I will explain a probable means for electrically transmitting a photograph.

If we make what photo-mechanical operators call a *screen* negative of a portrait, using a coarse screen, and from this a photo-lithographic transfer, transfer it to zinc, and transmit the result by any of the several autographic systems, we have the desired result. In fact, if we apply our knowledge of *half-tone block* making to telegraphy, we are at once in possession of a means of electrically transmitting the photographic semblance of any person.

We may make a *screen* negative, and from that obtain a print on zinc or copper coated with sensitive albumen or bitumen, using the usual solvents, water or turpentine, as the case may be, with which to wash away the unexposed albumen or bitumen, then let the stylus of any autographic system traverse the developed image, the result at the receiving end is a facsimile portrait. I have used the expression *screen negative*, as it is an understood trade name ; as a matter of fact, a *screen positive* would be necessary. We may go further, instead of receiving the facsimile on chemically-prepared paper, as in the Caselli autographic telegraph, we can make the receiving stylus perforate thin paper (with the electric spark) by means of a constantly-working induction coil, but only put into the receiving circuit by the transmitted current. Place this paper on a lithographic stone or zinc plate, pass a roller charged with greasy ink over it, and we have a *printing surface*, the portrait being *transmitted and reproduced for the printer*, photo-electro-mechanically.

But this is not telephany ; the latter must be understood as the means of transmitting images which may be in motion, as seen in a photographic camera, but not in colours.

Having spent some years in studying the problem, I designed the following system five years ago, as my Victorian scientific friends can testify. It may be of much assistance to workers in this direction. I think it offers a fair approximation to the solution of this very difficult problem ; at any rate, if in its present form it is not the actual solution, I feel sure it is in the direction indicated by my method, that the successful accomplishment of telephany will result.

## Transmitter.

L (figs. 1 and 5) is a photographic objective of the rapid type, producing an intensely illuminated aerial image at A A.

D D (figs. 1, 2 and 5), light metal disc revolving at a fixed rate of not less than 650 revolutions per minute under the control of La Cour's phonic wheel and fork apparatus as in the Delany multiplex system.

G (figs. 1, 3 and 5), a glass or other insulating plate, to the front surface of which is held, by binding terminals,  $S_1$  S, two triangular pieces of metal just separated from each other, E E.

C (figs. 1, 3 and 5), a small piece of lamp-black, selenium or other substance, the resistance of which may be varied by heat or light. Lamp-black compressed is probably the most suitable.

The disc, D D, has a series of small holes, 1, 2, 3, 4, 5, 6, 7, 8, perforated in it, and gradually approaching its centre, as a spiral, these holes must be numerous, and yet only one at a time in the field of the image at A A.

R L (figs. 1 and 5) is the most important part of the transmitter. This I term the regulating lens ; it is a lens placed with its plane surface just to receive the aerial image from the objective L, its focal length being such as to bring all rays reaching it through the perforated disc to a point or focus at C, and therefore its function is to introduce them consecutively to the circuit comprised in  $S_1$ , E, C, E, S.

Under the influence of this regulating lens the whole image, A A, is allowed to act in consecutive manner, and therefore vary the resistance of C in accord with the lights and shades of the original. We thus solve the big problem of translating the plane image into a line of consecutively varying strength of current, and by bringing C under the influence of the whole image within one-tenth of a second, and during the same time reconstruct our image at the receiving station, persistence of vision will enable us to see the image as one impression.

## Receiver.

$S_1$  (figs. 4 and 5), any artificial source of light, a beam of which is by means of lens, L, passed through a pair of Nicol prisms, P, A, this beam reaching lens  $M_1$ , is magnified and received by the eye-piece, M, M, and viewed by the eye, E. It is absolutely requisite this beam be received by the eye through optical means. The presence of a translucent screen at X, X, would be fatal, owing to the delicate nature of the desired effect.

D D (fig. 4), is a perforated disc, similar to and revolving synchronously with the disc in transmitter.

K K (figs. 4, 5 and 6), terminals inserted in glass and having a small space between, holding a drop of bisulphide of carbon, S.

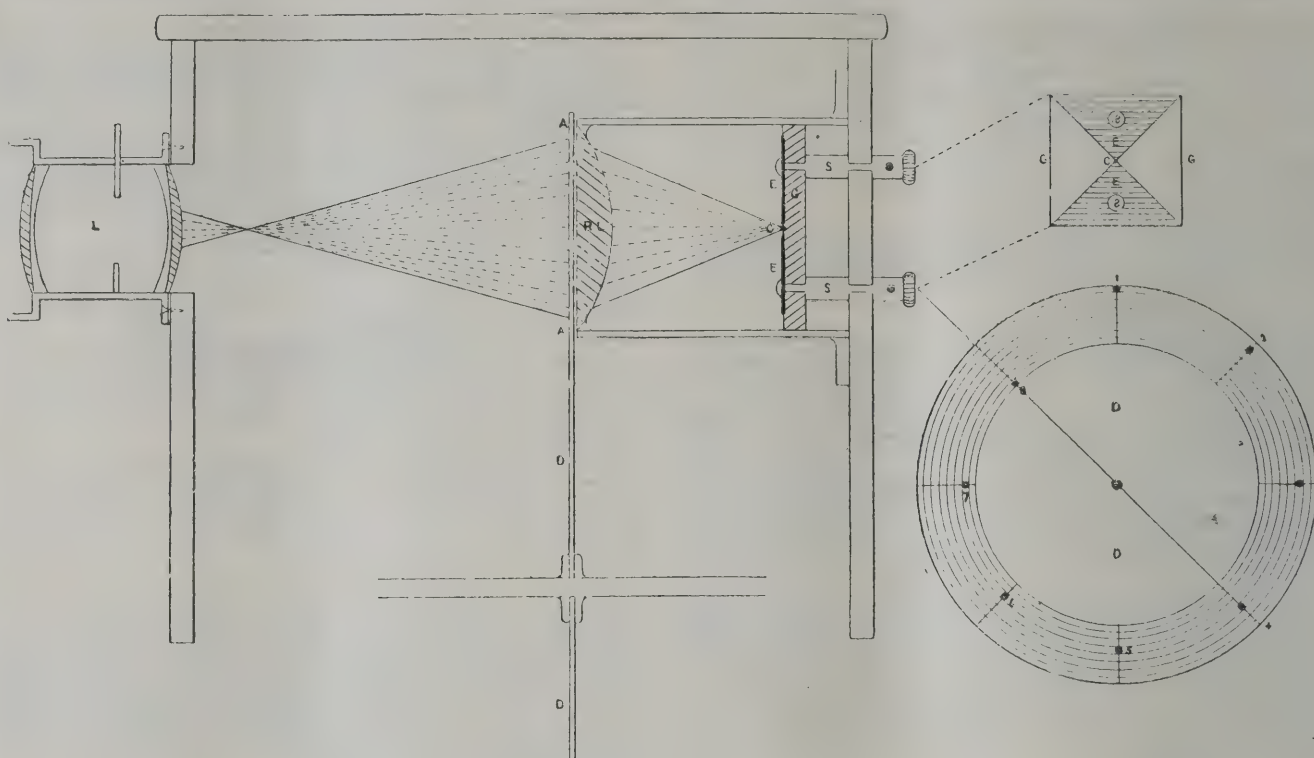

On rotating the Nicol, P,  $45^\circ$ , we reach the position of extinction.

The terminals, K, K, being placed in the secondary circuit of the transmitter—that is, to line—the variable electrostatic strain produced in the drop of bisulphide of carbon under the action of induced currents received from transmitter, is to produce variable rotation of the polarised beam, and, therefore, variable quantities of light reach the eye, E.

It is obvious the varying tints will be seen in similar position as in original image, owing to the synchronous movement of the discs.

The receiver is, then, based on Dr. Kers's discovery of the rotation of a plane polarised beam of light, through electric stress producing a strain in the medium.

There seems to me no question that the electric impulses will do their work within one-tenth of a second, and the point is whether the stress at O O will be sufficient to produce an observable effect, and whether this may be increased by passing the light through a bisulphide of carbon cell having a longer path of, say,  $\frac{1}{16}$  inch diameter, as shown at fig. 6, instead of through the drop of bisulphide ; so that, conceding the telephane is based on a rightly conceived principle, it becomes a

FIGS. 1, 2 AND 3.—TRANSMITTER.

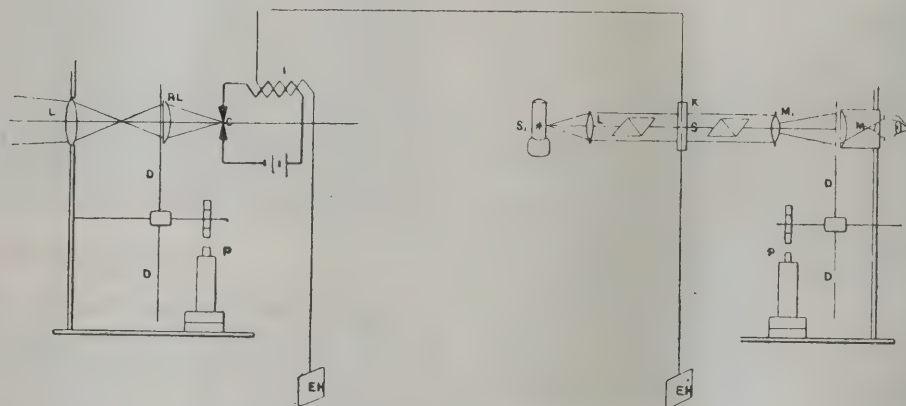

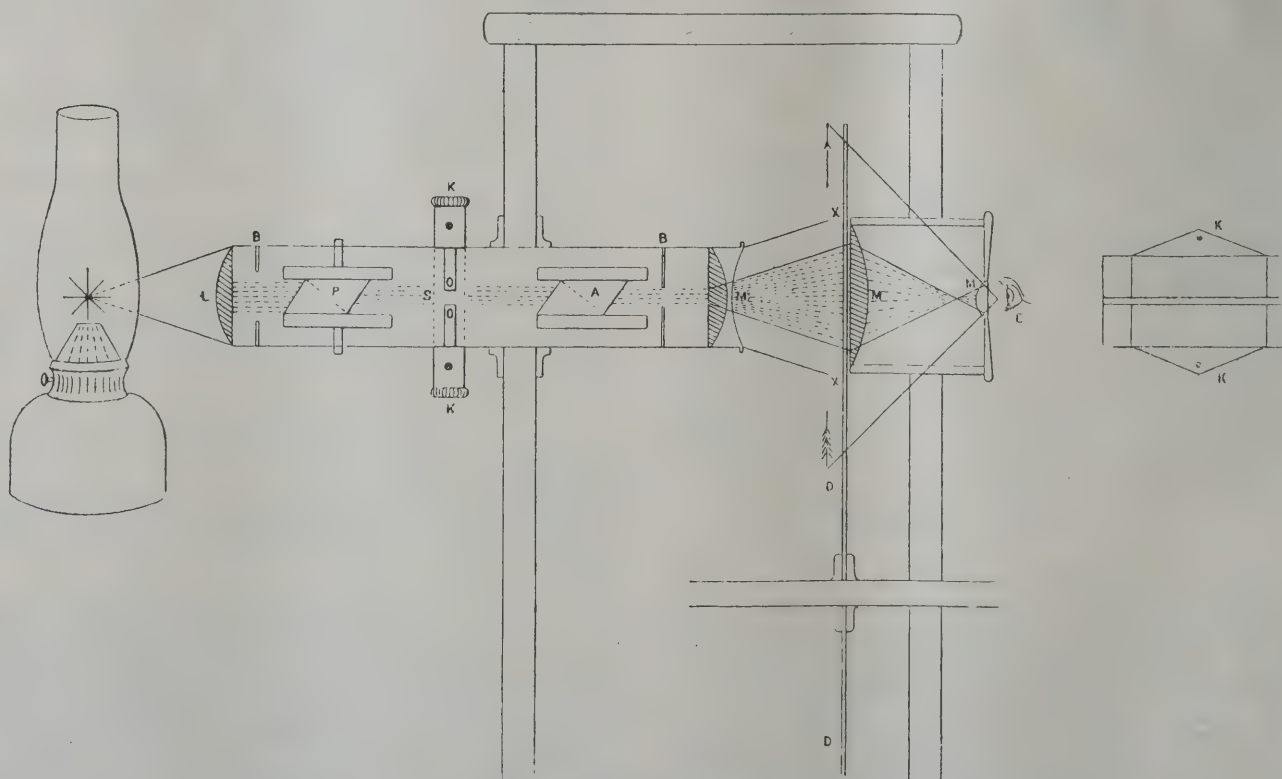

FIG. 5.—ARRANGEMENT OF CIRCUITS.

FIGS. 4 AND 6.—RECEIVER.

question whether the quantitative results of the physical effects utilised in its design are sufficiently great.

I think the transmitter may be considered as near the right thing as the present state of our knowledge will admit us to reach; there is an appearance of finality about it.

With regard to the receiver it is a question of degree; the actual quantity of light required to reach the eye may be very small when received optically; in fact, so small as to have no power of illumination on a translucent screen; but a quantity of light producing no visible effect on any media, when received by means of an eye-piece shows a bright disc. Owing to being away from references, I regret my inability at the moment to give the name of the inventor of the revolving disc; with the exception of these discs the whole design is original, and was devised at Ballarat, Victoria.

## INDUSTRIALISM.\*

By W. B. ESSON.

WHEN the Old Students' Association did me the honour to nominate me as President, I mildly suggested that by way of innovation this address might be dispensed with. The committee received that proposal, however, with open derision. Individually and collectively it smiled while declaring that the suggestion had been made before, annually in fact, and just as often as a president had been nominated. The committee remaining inexorable, the serious business of choosing a subject had to be considered, and I may confess that considerable difficulty was experienced in the selection. One does not want to talk as a specialist on such an occasion, as the address can then interest but a few. One wishes, if possible, to say something in which all the members will feel some interest, notwithstanding the diversity of the pursuits in which they may be severally engaged. And surely there is in their occupations plenty of variety. The Old Students' Association includes among its members men occupying positions in every department of applied science. In the numerous branches of civil and mechanical engineering, in departments devoted to the several applications of electricity, and in most of the great chemical industries we find the Old Students' Association represented. And this, I believe, is common to most of the representatives, that each in his particular sphere strives with might and main to achieve success.

But whatever branch of industry we may be engaged in, at some time or other we have attended the classes for technical instruction, conducted under the auspices of the City and Guilds of London Institute. It may have been for a long or short period at the Central Institution, at the Finsbury Technical College, or in a subterranean chamber in Cowper Street before either of those places was built. Anyhow, the scattered members of this association, with their many diverse interests, are united by the bond of that old studentship and the memories which cling around it. True, we can boast of no ancient pile or venerable quadrangle echoing the voices of the past, but if we are without the historical associations and traditions of an ancient university, we are at least free from its "dead languages and its undying prejudices." We are distinctly with the moderns. We went in for a liberal education, and for such preparation as was rightly or wrongly conceived to best fit us for rising to a place from the ranks of modern industry. Our object was to win, if possible, in the industrial struggle—in short, to make a living.

And here, I think, we touch common ground. We are all engaged in fighting, with more or less success, the battle of life. We are all performing some function in the world of industry. We are all trying to make a living. In endeavouring to find a suitable subject for my address these reflections occurred to me, and it then struck me that I might occupy your attention for a short time with the all-important subject of Industrialism, a topic of vast interest to all classes of the community, since it involves problems the solution of which is becoming pre-eminently the question of the present as it will be that of the future.

Industrialism is a growth, and the present highly specialised methods of production have been evolved gradually from the ruder processes of the past. In savage communities there was no variety of individual occupation. By turn a warrior, a hunter, a fisherman, a tool maker or builder, each lived independently of his neighbour, concerted action only being taken for the purpose of defence. But in time, individuals showed special aptitudes for particular kinds of work. Some displayed special abilities in making weapons, while others, more intrepid and courageous, showed a more decided inclination to use them. In a sort of understanding that the men who made the weapons would be furnished with food by the hunters who used them, we can easily

understand a crude division of labour to have had its origin. From a remote savagery through the ages which elapsed before men began to learn much of the arts of civilisation, the principle of the division of labour continued to develop the skill afterwards directed towards the arts of civilisation, being first engendered and fostered by the arts of war. "If we go back to the Stone Age," says Mr. Herbert Spencer, "we see that the implements of the chase and the implements of war are those showing most labour and dexterity. If we take still-existing human races which were without metals when we found them, we see in their skilfully-wrought stone clubs, as well as in their large war canoes, that the need of defence and attack were the chief stimuli to the cultivation of arts afterwards available for productive purposes. Passing over intermediate stages we may note in comparatively recent stages the same relation. Observe a coat of mail or one of the more highly finished suits of armour—compare it with articles of iron and steel of the same date; and there is evidence that these desires to kill enemies and escape being killed more extreme than any other, have had great effects on those arts of working in metal to which most other arts owe their progress. Indeed, it may be questioned whether in the absence of that exercise of manipulative faculty which the making of weapons originally gave, there would ever have been produced the tools required for developed industry."\* But in addition to fostering industrial art, war slowly brought about the conditions which made an industrial state of society possible. It was by force of arms that small nomadic hordes were welded into large tribes, that tribes were welded into small nations, and that small nations were welded into large nations. Only by the social aggregation arising from warfare were produced the conditions under which the division of labour could be developed to any considerable extent.

Contemporaneously with the development of industry grew the distinction which gradually became more emphasised between the regulating and the regulated classes. In primitive tribes the chiefs worked like other members with their own hands, and were only distinguished from them by more than usual valour exhibited in attack or defence. All fought when the need arose, and the separation of the chief from the rest of the tribe, his ceasing to work with his own hands, his gathering around him warriors distinguished by their valour, his dividing amongst them the lands of conquered races, the rise of feudalism, its ultimate decay and the advent of wage-paid labour were amongst changes which the slow roll of centuries gradually brought about.

Coming to the Middle Ages, we find the arts of civilisation considerably advanced; towns growing and Industrialism advancing as militancy decreased. The oppression of feudal lords pressed hardly, however, on the growing industries, and labour was burdened with heavy taxes to maintain large numbers of military retainers in a state of idleness and comparative luxury. "The old freemen formed their Frith-Gilds against the tyranny of mediæval magnates,"† and to defend themselves against the extortionate demands of lawless barons who were continually waging war against each other and levying the cost of their "expeditions" on the struggling industries. The history of those old-world combinations is extremely interesting reading, but here we have no time to do more than mention their existence; we are only skimming over their history in order that we may more completely realise that the present is unquestionably born of the past.

"So long as the towns were struggling against adversity, all the citizens worked together with public spirit and enterprise to secure their common welfare, but when a town had fully achieved its freedom and began to prosper, the oldest families of traders began to insist on their own privileges as the only proper full citizens and as members of the Town Gild."‡ While it was necessary they welcomed the combination of the craftsman against their common enemies, but as the need for such combination diminished, the aggressiveness they manifested against their inferiors increased. To resist the pretensions of the old burghers, those who worked at different trades accordingly formed themselves into craft-gilds, and for many generations the struggle between the two classes was carried on. But at length the victory was gained by the younger and more vigorous combinations of handicraftsmen. "In one town after another the craft gilds, leaguering together, overthrew the town gilds, and obtained mastery of the town,"§ governing it afterwards in their place for many generations.

In early times comparatively little capital was required for production. Industry was carried on by hand labour, and there was no expensive machinery to purchase and keep in repair. Then, the advantage of gathering many workers under one roof had no existence, and employer and employed were practically on the same level. Each craftsman worked with his own hands and in the same room with his workman, being aided by two or three hired journeymen and an apprentice, who became in course of time a craftsman himself. The relation of master and servant was, in those days, almost patriarchal in its character. The man was brought into close contact with his employer daily and hourly, and the identity of interests was recognised by both, for the class war between capital and labour had not as yet commenced. Again, good work was done in these old days. The gilds took care that only capable craftsmen should be permitted to join their associa-

§ *Ibid*, page 46.

tion, and the standard of work was well kept up. They were charitably inclined, and insured the worker and his family against want in case misfortune overtook them. While their influence lasted, the guilds were in many ways useful, but they had their day, and a time came when the attempts to regulate trade, and the various restrictions they imposed on industry, became harmful. Then came a reaction, and the guilds had to go, as have all institutions which lack the power to adapt themselves to a changed condition of existence. They lost their influence; advancing industry would not be restrained in the old grooves, and the guilds refusing to yield, it forthwith burst the barriers they had set up, and moved on in spite of them.

I have said that in early times there was little difference socially between the craftsman and his journeyman. But time brought a change in this respect. The craftsmen prospered, and their savings accumulated; capital began to grow, and the gulf between master and man, which was at first an almost imperceptible fissure, gradually widened. The former had grown rich, and had ceased to work with his own hands, or associate with his workmen. As his wealth grew, he employed more labourers, whom he treated in much the same way as he himself had been treated by the old burghers in former times; and in combining to protect themselves against the aggression of the rising capitalists, the workmen followed the example set by the craft guilds when they resisted the claims of the frith guilds. So we see that there is manifested the same kind of tendency all through the history of industry. Nor is the reason far to seek. While tribes were engaged in constant strife, Industrialism was born [and nursed in the lap of warfare. The arts were cultivated chiefly as a means of defence against the inroads of enemies or of conquering neighbouring tribes. Men were barbarians, and their adaptation to the restraints imposed by their living in the society of others had scarcely begun. Through centuries of warfare, of violence and bloodshed, Industrialism slowly struggled, civilisation progressing painfully and only as fast as savage hordes settled down to peaceful occupations. But though warfare nursed Industrialism, consolidated scattered tribes, and by its discipline converted a savage incapable of continuous application into the man who, as a citizen, works from morn till eve, it left, alas! its bitter traits behind. In early times every member of the tribe was a fighter, and only slowly was the separation at first partial, between soldiers and citizens accomplished. The latter were liable to be called upon for military service, for a long period, and when the separation was complete it was a soldier who had become a citizen. A soldier, inasmuch as he or his ancestors had been trained in cruelty, disciplined in butchery, had been schooled in treachery, and had revelled in bloodshed. And with this inheritance from the past, bearing in mind how slowly human nature changes, and how very gradual has been the process of adaptation to the social condition so far, is it any wonder that citizens should have manifested, though in a less degree, the aggression and the cruelty, and the persecution of former ages? Is it matter for surprise that Industrialism should have displayed to a large extent the character of the militancy from which it was developed?

But we come now to the end of the seventeenth or beginning of the eighteenth century, when began that new era of steam, by which the world has been revolutionised. It was for pumping the water out of mines that Thomas Savery, in 1698, took out his patent for an engine to raise water by fire. I need not describe this engine, which to most of you is probably well known. As a pumping engine it was of course very inefficient, its duty being something less than one-tenth that of a modern one. But there is one thing I would mention here as illustrating the opposition at that time to the introduction of any appliance which appeared to dispend with hand labour or render a less number of workmen necessary. In a letter addressed to the "Gentlemen Adventurers in the Mines of England," Savery apologises, in a measure, for his invention, saying, "As for pump making, that part of the trade will be much improved by my engine, for I must use board and timber for pipes, and have considerable employment for pump makers and carpenters for timber used about my engine. For my design is not in the least to prejudice the artificers, or, indeed, any other sort of people by this invention, which, on the contrary, is intended for the benefit and advantage of mankind in general." This language from an inventor implies the state of feeling at the time with relation to labour-saving devices. In 1712, an improved pumping engine was erected at Wolverhampton, by Newcomen and Cawley, who gave us the beam to be found in the modern type. Following Newcomen, we had Smeaton and others, who made great improvements, but it was left for the genius of Watt to make, from 1769 to 1782, those radical changes which have stamped the great inventor for all time as the father of the modern steam engine. At first, his engine, like previous ones, was used only for mining purposes; but soon he invented his methods of converting the reciprocating motion of the beam into the rotatory motion required for working machinery. For the pump rods were substituted the connecting rod, with its sun and planet wheels; the steam engine was thus rendered applicable to any purpose of industry, and became the greatest power for good—some would say for evil—the world has ever seen.

In the middle of the eighteenth century, the industries of the country were carried on, to a large extent, in the homes of the operatives. In the first stage of cotton manufacture, for example, the weavers, dispersed in cottages throughout the country, wove their webs from yarn spun by their wives and children on the common hand-wheel or distaff. At the same time, the weaver cultivated a small patch of ground, and, to us living midst

the toil and toil of this nineteenth century, the picture of domestic industry and family life, thus presented, is very pleasant to dwell upon. Honest John Ruskin, whose heart in matters of political economy is very much better than his logic, may not be quite alone in lamenting the gradual extermination of those rural workers. But lamentations are worse than useless. The system of those days represented but a phase in the history of industrial development, it disappeared to give place to another, it was but transient as is indeed the system of our own times. Distance is apt to lend here, as elsewhere, enchantment to the view, and it is not unlikely that the workers' lot in those days was, taking all things into consideration, harder than it is now. In 1767 the spinning jenny was invented by Hargraves, and a few years later, Arkwright constructed spinning frames in which were utilised Wyatt's, Paul's and High's inventions for spinning by rollers. To work these new machines water-power was employed, and from this period dates the rise of textile factories. "For several years," says Mr. Redgrave in his report for 1875, "the textile industry was carried on in the rural districts only. . . . Water on the hill sides was irregular in its flow; work was therefore irregular; when the stream was full, work was brisk (we should have called it excessive); when it was dry the factory hands were employed on the lands in haymaking, or other like occupations. Thus the operatives were both farm labourers as well as factory workers; and as manufacturing was not the complicated affair that it is now, they were free from many evils which afterwards arose from the introduction of steam and the immense energy and enterprise of our manufacturers." The application of steam to the working of machinery created the factory system proper. Inventors had not been idle, and numerous improvements had been effected in several directions. Cartwright had invented his power loom in 1784, and in 1785 Boulton and Watt erected in a factory at Papplewick the first steam engine applied as the moving power for spinning machinery. Progress was now rapid, and in every department of industry invention was producing new improvements. The rising seats of industry had been connected with each other and with the sea by canals. Large steam factories were erected, and tempted by higher wages and the promise of constant employment, armies of workmen came to fill them from the rural districts. Capital now became a huge power in industry, and very soon occurred the opening skirmishes of the labour war which has continued ever since.

If we are to believe the writers of this period the miseries following upon the introduction of the factory system were very great. In many cases the capitalists made a bad use of their power. "They crowded their factories with apprentices, many of whom they took from the parish with a premium of £5 each. The factories were so unhealthy, and the children worked so hard and for such long hours, as to be seriously injured physically and morally."\* In the report already referred to, Mr. Redgrave calls attention to the bringing together, without previously providing adequate and proper means for accommodation, hundreds of families to fill the mills. "Then followed immediately the proneness to run the costly machinery, regardless of the waste of human life, health, and happiness for any number of hours that seemed good to the capitalist. The factory population appeared in time to have become a distinct race that was known at a glance, so defined were the effects of overwork and unhealthy dwellings upon the physical appearance and condition of the people." Nor did the moral condition of the workers improve. Improvident and intemperate they appeared to go from bad to worse. Due to higher wages and the correspondingly easier conditions of existence, population increased rapidly. While, in fine, an increase of wealth took place in the capitalist part of the community, increase of numbers took place in the operative part. While gold was coined for the master, children were multiplied for his mills.

At a very early period the State had attempted the regulation of industry. In the time of Edward III. there was enacted a Statute of Labourers which attempted to fix the amount of remuneration each labourer should receive. It was intended to keep wages down, but notwithstanding from 1388 to 1444 they rose from 50 to 100 per cent. In the time of Henry VII. there was a law which directed people at what fairs to sell their goods. In the time of Henry VIII. it was made penal to sell any pins but such as are "double headed and have their head soldered fast to the shank and well smoothed, the shank well shaven, the point well and round-filed and smoothed." During the reign of Edward VI. a statute prescribed that a person making a usurious bargain should be fined £100. In the time of Mary and Elizabeth, laws were made limiting the number of looms each master weaver might have, and stating how many more apprentices than journeymen he might employ. In the reign of James I. a very wise Legislature prescribed the quantity of ale which should be sold for a penny.† Laws fixing the rate of interest and the wages of labour, prescribing the price of food and the shape of wearing apparel, specifying the goods to be made and the method of their manufacture were multiplied. In fact, there was in those days scarcely any limit to the duty undertaken by the State. Nor is this surprising when viewed in the true light of history. The citizens had inherited an unlimited belief in the power of Government. Primitive tribes could only be successful in war as their soldiers obeyed without question the orders of their chiefs. Those tribes in which the subordination was greatest would accordingly

\* Marshall's "Economics of Industry," page 188.

† See Herbert Spencer's "Social Statics," p. 313.

survive, while those in which it was less would in time be weeded out. It was the one necessity of the militant type of society that subordination to the chief should be complete, and faith in him entire. But the general in battle was also ruler during the intervening periods of peace, and to him the people looked to adjust their industrial quarrels, as well as to lead their soldiers to successful battle. Again, "success in war must largely depend on that conformity to the ruler's will which brings men and money when wanted, and adjusts all conduct to his needs."\* Accordingly laws were made just as if industry, like armies, could be governed by force. The discipline of warfare had produced men whose nature it was to submit to control from rulers, and as Industrialism grew gradually out of the old militancy, men's natures changed but slowly in adaptation to the conditions of the newer régime. Somewhere between savagery and civilisation, partly industrial, partly military, society still believes the ruler all powerful. Every day the Government is petitioned to undertake some new work which it is assumed would be impossible of accomplishment by the community without its aid. Government may change its form, but the belief in its omnipotent character remains. Savage chiefs may be displaced by emperors and kings. Kings may delegate their functions to Parliaments. Parliaments may in time give place to Republican assemblies. But all through history the tradition of unlimited power clings to the rulers, nor will it disappear until man is completely adapted to the social state, and the last sign of militancy shall have disappeared.

I have said that workers became demoralised under the factory system, and appeared to go from bad to worse. Accordingly, the Legislature undertook to set things straight. In 1802 was passed the first factory Act proper, which directed that "the rooms should be washed well with lime and water twice a year; that apprentices should be clothed with two suits yearly, and should be instructed in reading, writing, and arithmetic the first four years; that the hours of work should not be more than 12 per day, exclusive of meals, and that work might be carried on by night in mills with 1,500 spindles." The rapid development of the steam engine changed the conditions of labour in a short time to such an extent that the Act was no longer applicable, and so, in 1819 and 1825, we have further Acts restricting the hours of labour and the work of children. It may be mentioned that in the textile industries the apprenticeship system had by this time disappeared, as the skill requisite for handling the improved machinery could be attained in a very short time. These Acts were followed in 1831 and 1833 by further Acts relating to textile industries, but in 1834 the Legislature extended its scope, and passed laws influencing other classes of operatives. Accordingly, we had soon Acts of all kinds for the regulation of mines and collieries, print works, bleaching and dye works, bakehouses, copper and iron works, machine shops, fish curing and fruit preserving. In fact, there are so many Acts, that no one knows very well where we stand, and a Factory Enquiry Commission has had to acknowledge that this branch of our laws has become very unwieldy, and wants unification.† That these several enactments made the life of the workers somewhat easier for a time may be true. But that they have produced any true and lasting good, except in so far as they have removed hindrances to the natural growth of Industrialism, the student of sociology is at liberty to doubt. And there seemed to be some such doubt in the minds of the workmen themselves, for trades unions, formed at first to petition Parliament to pass measures in their behalf soon found that the aid they required was not forthcoming, and that they would have to "rely as the guilds before them had relied, upon their own energies. They no longer approached the Government with the purpose of inducing it to interfere in their behalf; but they petitioned and agitated for the cessation of Government interference against them."‡ The conduct of the trades unions in the early part of the century was reprehensible in the extreme, and the opposition they manifested towards the introduction of machinery is a matter of history. It may indeed be doubted if working men have yet been intellectually convinced of the benefit of machinery. Anyway they had not been convinced in those days, and labour disputes were oftentimes accompanied by riots and bloodshed. By numerous Acts it had been made a crime punishable by fine and imprisonment to refuse to work for the purpose of obtaining higher wages, and "men who know they are criminals by the mere object they have in view, care little for the additional criminality involved in the means they adopt." However, trades unions have become more sensible, and one by one the combination laws have been repealed. The Legislature now recognises the combination of workmen for the purpose of bettering their condition as perfectly legal, provided that in carrying out their ends nothing is done by the combination which would be declared against law if done by an individual. The trades unions of to-day are in many ways analogous to the craft guilds of the past. They have for their objects, says Mr. Howell—(1) "to procure for their members the best return for their labour in the shape of higher wages, shorter hours of labour, and the enforcement of certain restrictions as to the condition of employment which could not be accomplished except by means of combination; (2) to provide mutual assurance for the members by means of pecuniary assistance in the case of sickness, accident, death, out of work, superan-

nuation when disabled by old age, loss of tools by fire, and emigration.\* These are principles with which no fault can be found, but, that they are often very superior to the conduct they are supposed to guide is a matter of everyday observation.

Well, gentlemen, these remarks bring me to modern times. Time has allowed me to notice only a few of the more important factors in the evolution of Industrialism. The growth of railways, the development of steam navigation, improvements in agriculture, electric telegraphs and submarine telegraphy, have each made enormous contributions to our industrial progress. But these by no means exhaust the list. It has been said that we of the nineteenth century are intellectually the heirs of all the ages, and not less true is it that present day Industrialism inherits a huge legacy from bygone centuries, has grown up by infinitesimal contributions of far away ages, as well as by the larger contributions of recent times. My history has been of a somewhat sketchy character, and the more so, perhaps, as here and there the narrative has been broken in the endeavour to emphasise the method of science in history. To thinking men, history is no longer a record of this or that sovereign's deeds, a chronicle of court intrigue or gossip of princely trappings. But it is the story of a nation's progress. It tells how institutions arise, flourish, and in time decay as new ones take their place. It shows how each successive stage of development arises from the one immediately preceding and gives birth to the one immediately following it. It recognises that the evolution of society proceeds in accordance with law, and that causation, though partially concealed by the extraordinary complexity of the phenomena to which it relates, must have here, as in all development, universal dominion. And so, as I have said previously, Industrialism is a growth, and the present methods of production have been evolved from the processes of the past. We have now huge factories employing thousands of workmen, and filled with self-acting machinery in which the division of labour is carried to the utmost limit. Whereas, in times past, it was necessary to spend years in serving an apprenticeship and learning several branches of a trade, in a great many instances the old apprenticeship system has been done away with, the whole of a lad's attention when he enters the factory being engaged in watching the one operation performed by an automatic machine. In all branches of the finished metal trades we are struck by the clever combinations of mechanism employed in the performance of the several operations, and as we watch machines rapidly doing their work with unerring precision, and requiring almost no attention, we may well wonder whether economy in production can go much further, whether adjustment of acts to ends can be rendered by mechanism more perfect. In the engineering trades similar division of labour is found and similar specialisation is apparent, though probably to a less extent. When I was an apprentice the old-fashioned millwright was not extinct. He was a man who could "put his hand to anything," as the saying is. He had served seven years' apprenticeship and could make his own patterns, forge whatever he needed, do turning and filing, and, on a pinch, might attempt brass-founding with metal melted over a smith's fire. He was a veritable Jack of all Trades, but he is no more. Modern industry does not require him and draws the line very distinctly between the several branches of the engineering trades. We have smiths who work forging machines and hydraulic press tools. We have turners, planers, slotters, shapers, drillers, millers and special tool men, each of whom has under his charge an expensive self-acting machine tool which it is his duty to look after and which it should be his aim to thoroughly understand. As Mr. Nasmyth says, "All that the mechanic has to do, and which any lad is able to do, is not to labour but to watch the beautiful functions of the machine."† In the shipbuilding trades the tendency towards specialisation is not less marked. In short, in every branch of industry the aim is twofold; first, to do as much as possible by machinery because hand labour is expensive; secondly, to restrict the function of the workman to performing one operation or to looking after one machine, because his whole thought being then concentrated on one thing, he soon acquires in his work special dexterity. The effect of the division of labour on the workman, when carried to excess, need not be here considered. On that point opinion is divided, some believing that constant employment, without variety, deadens a man's mental activity and resource, while others equally capable of judging hold that concentration on one operation sharpens a man's intelligence so far as concerns the sphere of his work, and gives him more opportunity for thought on subjects unconnected with his employment. However that may be, the division of labour is a great fact in modern industry, and as a means to economical production, there can be no question about its efficacy. The tendency is to carry it farther and farther, as concerns, by getting larger, are enabled to take the fullest advantage of the benefit it confers. It is the condition of production which Industrialism has by its natural development brought about.

But along with improved methods of production there has grown up within the century that vast distributive system which is represented by a railway capital of nearly one thousand millions sterling, and the direct employment of nearly half a million workmen. When we remember that these have to be fed, and clothed and housed; when we recollect that a large

number of workmen must be employed in providing the iron and steel required in the manufacture of rolling stock, and that materials and labour must be constantly forthcoming for the construction of lines in progress; when we perceive that this distributive system, rendered necessary by increased production, has in its turn stimulated production to an incalculable extent, we begin to realise, though but faintly, how far-reaching in its influence on industry railway progress has been. Then we have—as constituting a farther means of distribution—docks, in the construction of which millions have been expended, and a huge mercantile navy which, by the direct and indirect employment of armies of workmen, enable us to effect an advantageous exchange of our goods for those of other nations. Ships have to be built, and workmen have to be supplied with the means of life in return for their labour. The raw materials must be furnished, and the necessary iron and steel produced by another host of labourers. Nor is this all, for outside the artisan classes indirectly depending on distribution for a livelihood, are thousands employed in mercantile houses, shipping agencies, and brokers' offices, all occupied in effecting the distribution of commodities, not to speak of the hundreds of thousands engaged in wholesale warehouses and retail shops. Meditating on these things, I say we begin to comprehend now vast, how complex, how inter-dependent in all its ramifications Industrialism has become.

(To be continued.)

### A NEW ASBESTOS-FACED VALVE.

WE venture to think the valve we illustrate will meet a long-felt want by supplying a flexible seating which can be renewed, if necessary, in a few minutes, by an ordinary workman at a cost of a few pence, and for which no special tools are required.

The lettered section and description we give will, we hope, enable its advantages to be clearly defined.

A represents the form of seat adopted in this valve which, in addition to the ordinary angled seat, has a round edge to prevent damage to the packing ring, B, when the latter is brought into contact with it.

D is a loose valve, actuated in the ordinary manner by a screwed spindle working in gland of the valve top, which, when first set down, brings the packing ring, B,

on to the seat, A, and for ordinary pressures a perfectly tight and elastic joint is thus made, but, by setting the loose valve, D, hard down, the sliding cone, C, comes into contact with the angle of the seat, A, and being free on the guide stud, E, is forced into the chamber of the loose valve, D, and by compressing the packing ring, B, prevents it becoming damaged.

While the packing ring, B, is thoroughly protected by the lower projection of the loose valve, D, there is little tendency for B to become damaged by the passage of steam or water through the valve, but should it even become entirely washed out, a tight metal to metal seating is the result by A, C and D being brought closely together.

It is claimed that the valve through its elastic seating is not affected either by grit, dirt, expansion, contraction or uneven seating which makes it alike suitable for the highest or lowest pressures of steam, hydraulic, or general water valves by the insertion of packing rings made of the most suitable material to meet the various uses.

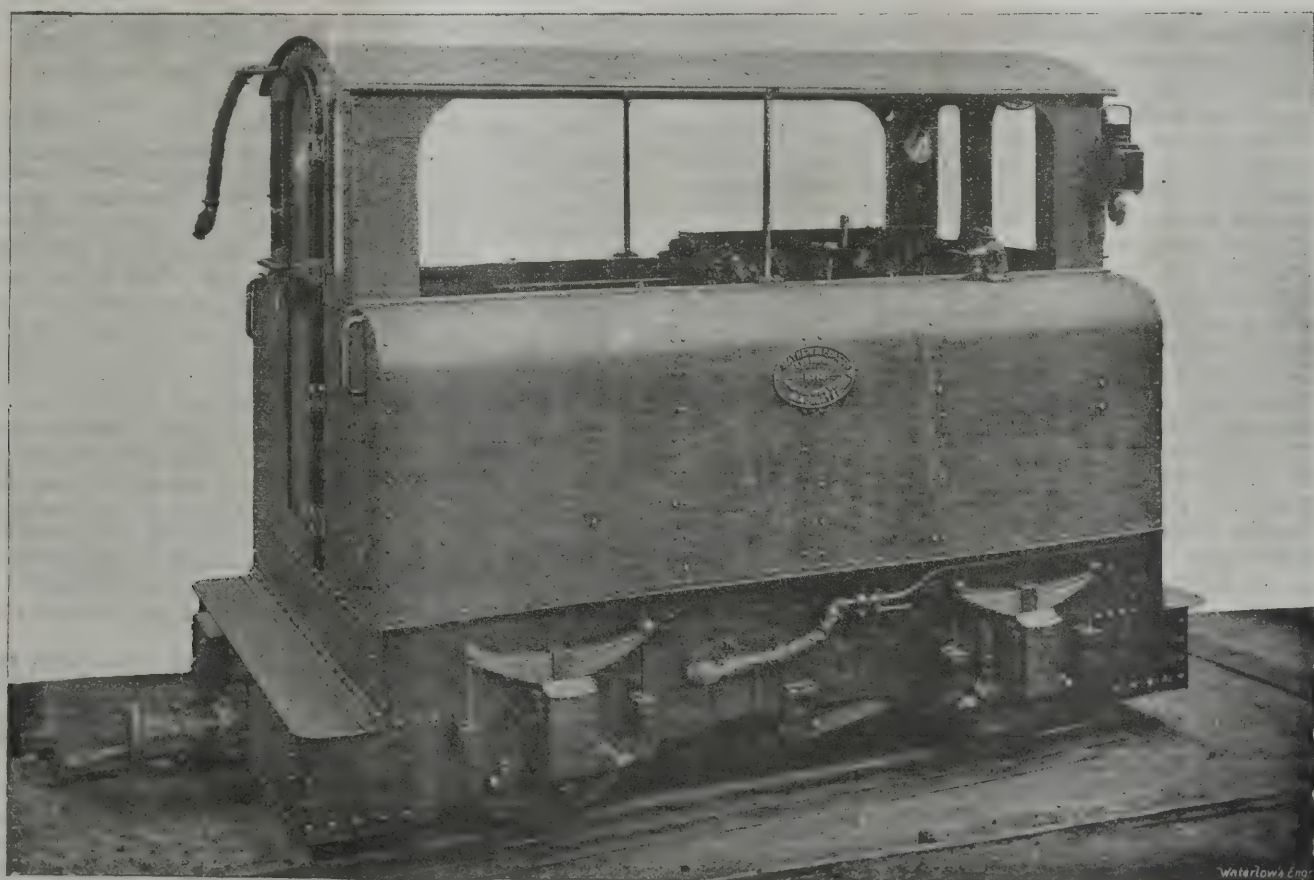

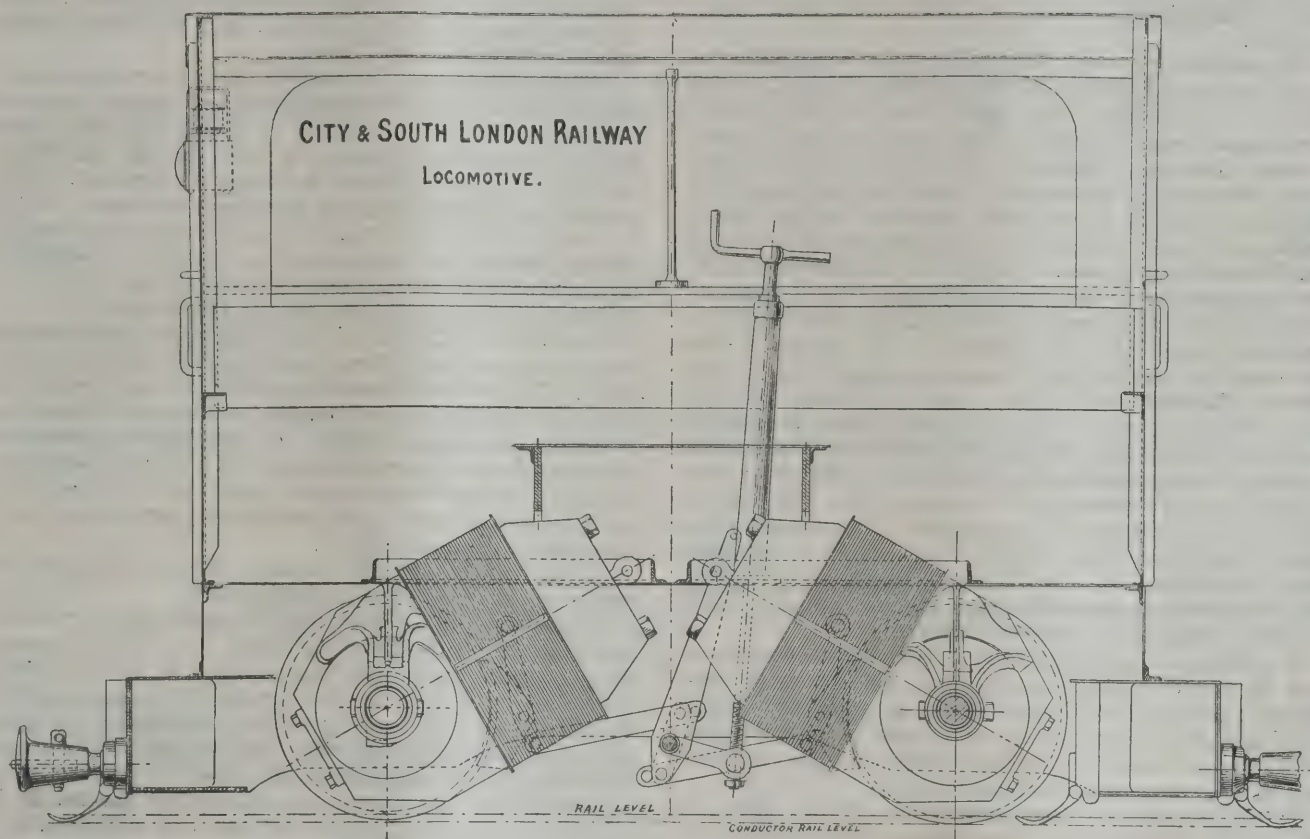

A  $1\frac{1}{2}$  inch valve, made under this patent, is said to have been under test for three months at a steam pressure of 100 lbs. per square inch and found to hold perfectly tight, after which it was put under hydraulic test, and by being lightly screwed down held a pressure of 2,240 lbs. per square inch.

The packing ring used for these trials was made up specially in asbestos, and is still in perfect order, and we are assured it has not been removed at any time during or since the above trials.

### THE CITY AND SOUTH LONDON RAILWAY.

THIS railway is a subway about  $3\frac{1}{4}$  miles in length, passing from a point in King William Street, City, under the Thames, and on to Stockwell, and constructed on a novel method, designed by Mr. Greathead, M.I.C.E., in the form of two circular iron tunnels 10 feet in diameter, driven throughout the London clay, about 60 feet below the surface, and at a cost of about £220,000 per mile.

The two tunnels, after having passed under the bed of the Thames, have been executed by the compressed air system, in the face of a subterranean difficulty which could hardly be exceeded—namely, a powerful underground river percolating through a gravel bed of large flints and coarse pebbles. This water-flow was kept back for weeks upon weeks by the sheer force of volumes of compressed air, whilst concrete and cement-grout were poured in front of the tunnel shield, and an artificial rock extemporised, in which the segments of the iron tunnel tube could be bolted together. For these and other engineering operations involved the just merit due to the resident engineer, Mr. Mott, should not be withheld. It is well further to note that the tunnels have been driven with exceeding accuracy and unrivalled speed. They were made in 400 yards lengths, 200 yards being driven from each face, and meeting like lengths driven from other faces. The extreme divergence of the junctions amounted in one instance only to seven-eighths of an inch, the others not exceeding a quarter of an inch, although the datum levels had to be transferred from the bottom of the shafts, which now contain the lifts, to the centres of the lines of tunnel, as the shafts were all on one side or the other of the line of railway. The rate of excavation was often as much as 16 feet per day, the average of the working days being 13 feet 6 inches advance of heading. All the anxieties of the engineering work are over, the rails of the road are laid, the platforms erected, and the neatly constructed underground stations, with their walls lined with white

VIEW OF LOCOMOTIVE.

glazed tiles, are ready for the passengers, and have a cleaner and brighter aspect than any of the other underground stations in London. Moreover, they will not be sullied with smoke and dirt from steam locomotives.

The scheme to work this railway by electricity to avoid the use of steam and its noxious results, or the use of rope traction with slow speed and other disadvantages, was submitted to the City and South London Railway Company by Messrs. Mather and Platt, engineers, Manchester. The company accepted the idea, which is entirely original in its main features, though based upon the experience obtained by Dr. Edward Hopkinson, a partner of the above firm, in the construction of the Bessbrook and Newry narrow-gauge electrical railway in Ireland, fully described in previous issues of the REVIEW. The contract for the carrying out of the whole scheme, designed by Messrs. Mather and Platt, was committed to that firm, who employed Messrs. John Fowler & Co., of Leeds, to supply the boilers and engines to work the dynamos for generating the current of electricity; also Messrs. Beyer, Peacock and Co. to construct the framework of their electrical locomotives. The whole electrical plant has been carried out under the special superintendence of Dr. Edward Hopkinson, F.R.S., who has acted throughout as consulting engineer, with Mr. G. A. Grindle as resident engineer.

A number of small tramways, both on the continent and in the United Kingdom, have been worked electrically, and in the United States many of the street tramways are worked in this way, but it has not hitherto been applied on any large scale to the working of a railway of the usual gauge for passengers.

The following are the particulars of the plan of Messrs. Mather and Platt, and details of various parts of the work:—

The whole of the machinery for generating the electrical current is situated at Stockwell, the suburban terminus of the line. At this point a complete plant has been erected for the generation of the electrical current. There are three large generator dynamos of the Edison-Hopkinson type, each worked independently by a vertical compound engine, designed and constructed by Messrs. John Fowler & Co.

The engines work at a steam pressure of 140 lbs. per square inch, and have been built of exceptionally massive proportions. They run at 100 revolutions per minute, giving a piston speed of 450 feet per minute. They are fitted with automatic expansion gear of improved type on both the high and low pressure cylinders, and are controlled by a powerful governor, which is driven direct from the crank-shaft by cotton ropes, the automatic gear being so arranged as to cut off the steam if necessary in both cylinders from dead cut-off to three-quarters of stroke. The engines will indicate up to 375 horse-power each. The cylinders are steam-jacketed, the high-pressure is 17 inches diameter, and the low-pressure 27 inches. The pistons are fitted with Mather and Platt's rings and springs; the valves are specially fitted with multiple ports, which reduces their movement considerably, and still gives a very prompt action. As the parts are as close as possible to the end of each cylinder, the loss of pressure by wire drawing is very small. The flywheels are 14 feet diameter and 28 inches broad, and drive the dynamos direct by means of leather chain-belts 26 inches wide.

The engines are supplied with steam from six Lancashire boilers, 7 feet diameter by 23 feet long, which are fitted with Vicar's mechanical stokers. Two large feed water heaters are also supplied, with brass tubes of ample surface, for receiving the whole of the exhaust steam from the engine without back pressure.

The generator dynamos are of the Edison-Hopkinson patent type, with bar armatures, fitted with all the latest patented improvements of Messrs. Mather and Platt. The weight of the armature alone is about 2 tons, and the weight of the entire machine something over 17 tons. Each machine is capable of generating 450 volts and 450 ampères. The commutators are of

hard copper insulated with mica, and there are three brushes on each rocking arm, each separately adjustable, with bring-forward thrust and hold-off catch. The magnet limbs are exceedingly massive, each limb, with its pole piece, being over 4 tons, and the yoke of the machine weighs about 3 tons.

The machine can be run as shunt, or compound only, as required. The total weight of copper wire on the magnet of each machine is nearly  $1\frac{1}{2}$  tons. The Edison-Hopkinson dynamo is well known as being perhaps the most efficient machine constructed. The present machines have an electrical efficiency of 96 per cent., or slightly over, and the measured efficiency of the engine and dynamo, *i.e.*, ratio of the electric power available outside the dynamo to the indicated horse-power of the engine, is over 75 per cent.

Sir William Thomson's multicellular electrostatic voltmeters are used for measuring the electromotive force. The current from the dynamos is conveyed to a general distributing and testing switchboard, fixed in a recess of the engine house. From this board the main circuits are taken to various parts of the line, and the current passing through each circuit is measured, and suitable arrangements are provided for switching over from one circuit to another.

A plan of the engine house is shown, and also an elevation of the engines and dynamos.

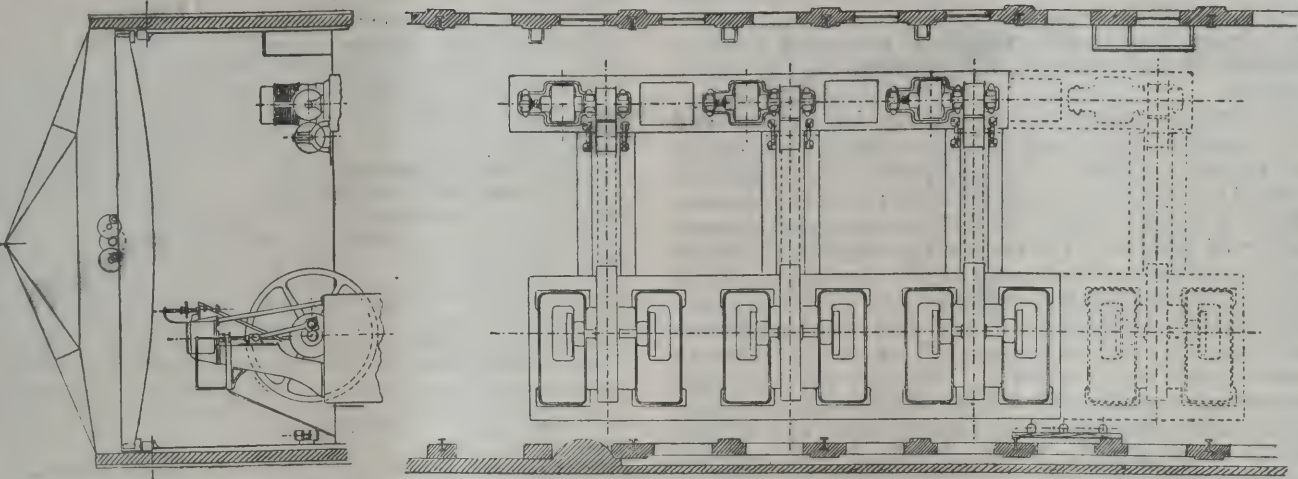

The site occupied is a plot of about two or three acres on the surface, or ground, level. The access between this dépôt and the subway is by a curved tunnel descending from above ground by a steep incline of 1 in  $3\frac{1}{2}$  feet. Up and down this the trains are brought or lowered by a rope and winding engine. This short bit of tunnel is remarkable. Formed on a horizontal radius of 250 feet and a severe vertical radius, it is marvellous that the junction of the two drivings, one from below and the other from above, should have met centre for centre and level for level within an inch or two. At the dépôt the carriage shed is large enough to contain six trains side by side.

The main cables have been manufactured by the Fowler-Waring Company, of North Woolwich, and consist of a copper core of 61/14 B.W.G., insulated with Fowler-Waring patent insulating material, and lead-sheathed.

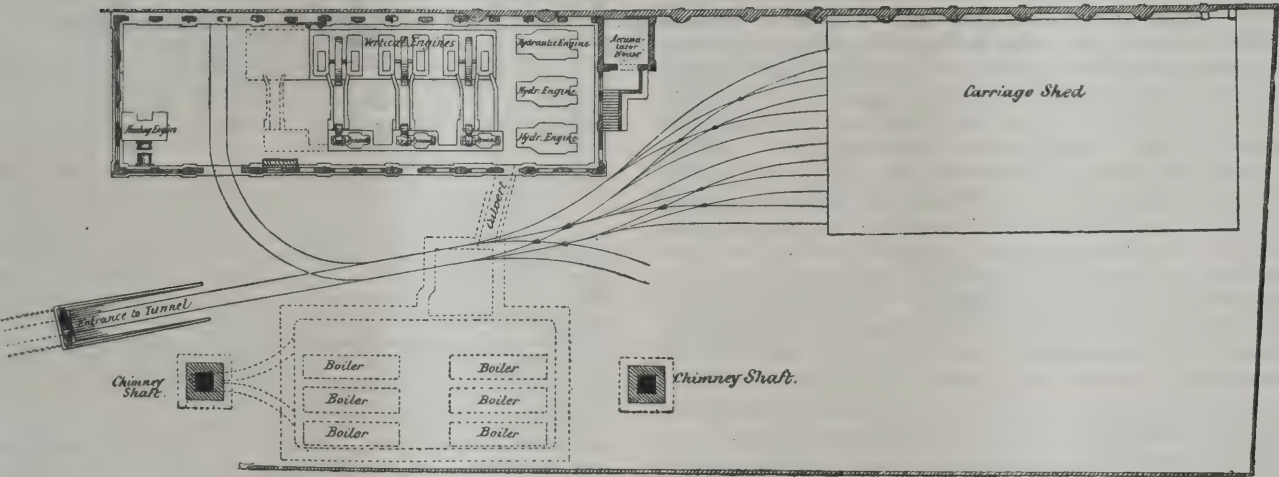

The working conductor is of channel steel, carried on glass insulators, the joints being fished, and also connected with copper strips. The general arrangement of the working conductor is exactly the same as that employed by Dr. Edward Hopkinson on the Bessbrook and Newry line. The steel employed is of very high conductivity, and has been rolled specially for the purpose by the Shelton Iron and Steel Company, of Stoke-on-Trent. The working conductor is divided into sections for convenience of testing and carrying out repairs on the permanent way. The insulation obtained is extraordinarily high. When the full pressure of 500 volts is on the complete system of working and feeding conductors, the leakage current does not exceed one ampère, so that the total loss by leakage is less than 1 horse-power; this is a small fraction of 1 per cent. of the total power required for working the line to its full capacity. The current is collected from the working conductor by sliding shoes of iron or steel arranged in a very similar way to that employed on the Bessbrook line.

Fourteen 10-ton electric locomotives have been supplied by Messrs. Mather and Platt for working the line, each capable of developing 100 effective horse-power and of running up to 25 or 26 miles per hour. The armatures of the locomotives are constructed so that the shaft of the armature is the axle of the locomotive, in this way all intermediate gear and all reciprocating parts are entirely obviated. The method was suggested by the late Sir William Siemens some years ago, but has not as yet been employed elsewhere. A motor is fitted on each axle, the axles not being coupled, but working quite independently. The current is conveyed from the collecting shoes through an ampèremeter to a regulating switch, then to a reversing switch, thence to the magnets and back through the framework of the

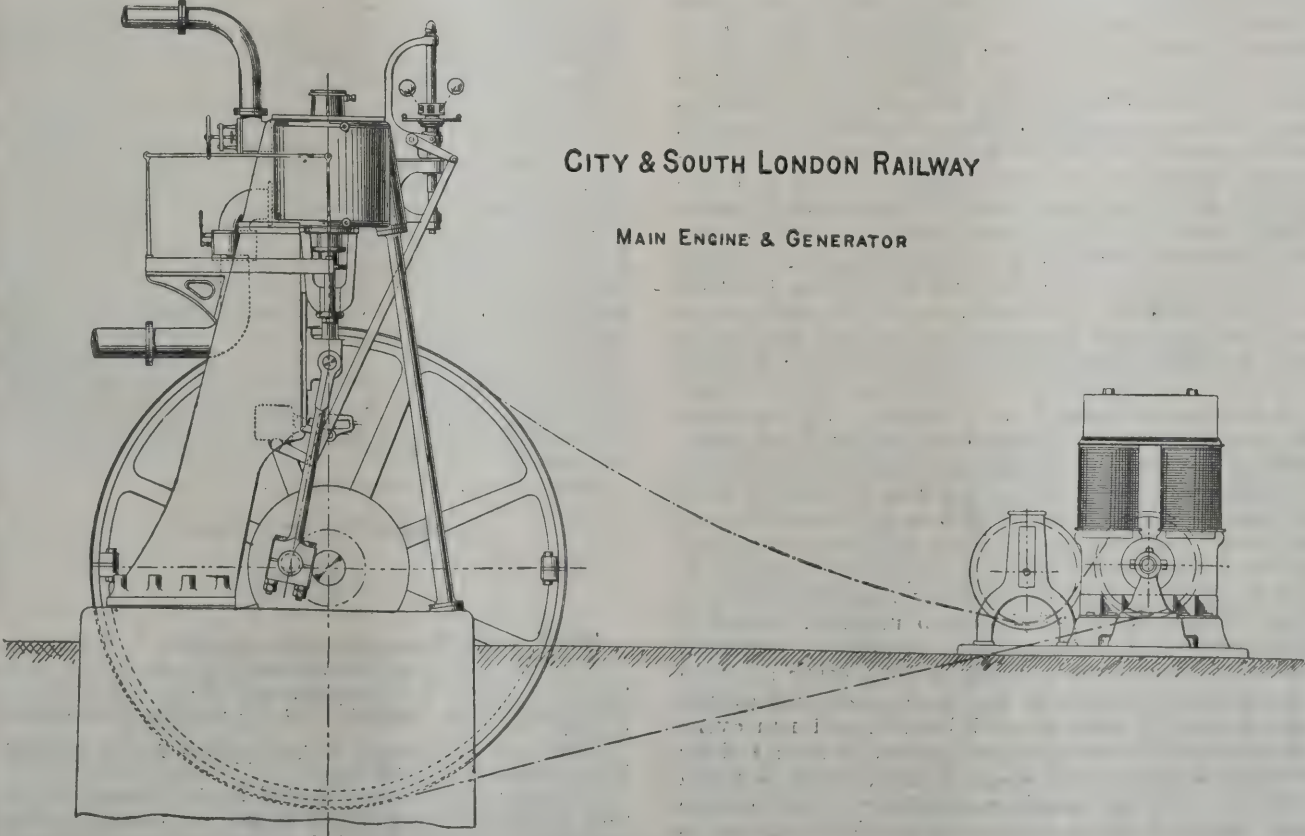

CITY & SOUTH LONDON RAILWAY  
DYNAMO HOUSE

CITY & SOUTH LONDON RAILWAY  
GENERAL PLAN OF GENERATING STATION

CITY & SOUTH LONDON RAILWAY  
MAIN ENGINE & GENERATOR

locomotive to the rails, so completing the electrical circuit. The locomotives are fitted with a Westinghouse automatic air brake and also a screw hand brake, and they are lighted from the working conductor. The train, when loaded, will weigh 30 tons, and it is intended that ten trains shall be worked on the line at one time.

A train consists of an electric locomotive and three passenger carriages 32 feet in length from end to end of the footboard. The long passenger carriages are pivoted on two four-wheeled bogies; and the interior, which is divided by a door in the centre, contains seating for 34 persons. The enclosed portion is 28 feet in length, the external overhang of the carriage platform being coupled up to the similar overhang of the adjoining carriage, and thus forming two open platforms between the three carriages. Upon each of these a guard travels with the train. These guards' platforms are protected at the sides by iron lattice sliding doors. The carriages are lighted by electric light, the current for the lamps being, in like manner, taken off from the conductor.

Each train carries its own reservoir of compressed air, sufficient for 40 stoppages, and as it arrives at the dépôt station of the line, recharges its air supply. The trains are also fitted with hand brakes, the stopping power being thus completely independent of the motive power. Block signalling has been adopted. Should, by any failure of the engine at the dépôt, or any other cause, the train be brought to a standstill, passengers could leave the tunnel safely, as a passage 2 feet wide is provided, clear of the rails, and at no point could the distance to be traversed exceed three-eighths of a mile.

In the generating house is the hydraulic machinery for supplying power to the lifts at the various stations. The cylinder of the ram is 2 feet in diameter, and the wrought iron flange-jointed pipes, which convey the water at a pressure of 1,200 lbs. on the square inch, are nearly a foot in external diameter. The engines which pump the water into them act automatically, being put in motion as the accumulator descends by loss of water at the lifts. At the end of this building is a locomotive repairing shop, with special appliances for lifting out or replacing the dynamos on the locomotives.

The arrangements along the whole line for public traffic are well advanced, but will, probably, not be completed for some weeks yet. The City terminus is in King William Street; the other stations are Great Dover Street (Borough), the Elephant and Castle, Kennington Horns and Oval, and Stockwell. The lifts at all five are of the same type, namely, semi-circular in form, and carry 50 persons at a time. Two such lifts work in the same shaft 25 feet in diameter. No tickets will be issued at booking offices, but passengers entering from the roadways will pay their money and pass through turnstiles, going down by the lift or by stairs at their option. At the outset, when the subway was begun, rather more than three years ago, it was thought to start the running of the line as between the City and the Elephant and Castle, but as the engineering work proceeded, the directors thought that section too small for remunerative commercial working; and obtained an Act to continue the subway to Stockwell, with powers to extend it to Clapham. The carriages are all alike-cushioned and comfortably fitted, there being no distinction into classes. The charge, too, will be uniform, twopence being the fare for the whole or any part of the distance. For the numbers of business men, clerks, and *employés* coming daily into the City it will be a great boon to be conveyed at a speed of at least 12 miles an hour, the journey from Stockwell to King William Street occupying 15 minutes, instead of three-quarters of an hour as at present by omnibus. Ultimately, the trains will follow each other at three minutes intervals, but at the commencement of the traffic they will start about 7.30 a.m., and run every five minutes. The stations are lighted by gas; and for the water supply of the steam boilers, which is taken from the water company's mains, there are two large tanks, one of 12,000 and the other of 25,000 gallons, as a reserve.

## LONDON COUNTY COUNCIL.

THE ordinary weekly meeting of the council was held on Tuesday, with Sir John Lubbock in the chair.

The report of the Highways Committee stated that the committee have considered an application by Mr. H. C. Godfray, on behalf of the North Metropolitan Tramways Company, for the consent of the council to the use by the company, for a period of seven years, of electrical power on its tramways between the Swan public house, Upper Clapton, and the terminus at Moorgate Street, by way of Upper and Lower Clapton Roads, Mare Street, Hackney Road, Old Street, and City Road. Section 4 of the Company's Act of 1890 authorises the use, subject to the consent of the council as the local authority, and of the Board of Trade, of electrical power on the company's tramways or any part thereof, and the Board has power to make bye-laws for the safety of the public and the proper regulation of the traffic. The system proposed to be adopted has been for the last 12 months in operation on the company's lines in Barking Road, outside the County of London; and the committee, having fully considered the matter, are of opinion that, subject to certain conditions, the consent of the council may be given to the use of electrical power on the lines referred to in the application. They therefore recommend:—

That the council do consent to the use by the North Metropolitan Tramways Company, for a period of seven years, of electrical power on its tramways between the Swan public house, Upper Clapton, and the terminus at Moorgate Street, upon condition that previously to such use the company shall put the said lines of tramways into thoroughly good condition, to the satisfaction of the council, and shall undertake to adopt such precautions as the council may from time to time require to be taken for the prevention of injury to the public from the batteries and other machinery of the cars to be used on the tramways.

The Kensington and Knightsbridge Electric Lighting Company has given a notice, dated October 22nd, 1890 (registered No. 126), of an intended extension of mains in Palace Gate (1 plan). There seems to be no objection to this, and the committee recommend—

That the sanction of the council be given to the works referred to in the notice (registered No. 126), dated 22nd. October, 1890, of the Kensington and Knightsbridge Electric Lighting Company.

A notice (registered No. 127), dated October 22nd, 1890, has been received from the Electricity Supply Corporation, Limited, of proposed works in the Strand and Bedford Street (1 plan); but since the date of this notice the company has intimated its intention to serve a further notice with reference to works over a larger area, and that it does not wish to proceed under the first notice. In these circumstances the committee recommend—

That the council do formally disapprove of the works referred to in the notice (registered No. 127) of the Electricity Supply Corporation, dated October 22nd, 1890.

The Westminster Electric Supply Corporation has submitted a plan of the culverts proposed to be used for the company's mains where they cross the carriage-ways. The committee are of opinion that the proposed culvert would, with a slight modification suggested by the council's engineer, be satisfactory, and they recommend—

That, subject to the modification suggested by the council's engineer, the council do approve the plan, submitted by the Westminster Electric Supply Corporation, of culverts to be used for mains where crossing the carriage-ways.

The report of the Parliamentary Committee said, with reference to overhead wires, that on the 21st October the council instructed us, in conference with the Building Act Committee, to give such notices as might be necessary to enable the council to introduce a Bill, or clauses in a Bill, to prohibit or regulate sky signs; and on the 28th instant the council passed a resolution directing that the Bill of last session relating to overhead wires, in the form in which it passed the Select Committee of the House of Commons, subject, however, to such modifications as we might consider necessary, should be again introduced into Parliament next session, and it was referred to us to give the requisite notices, and to take the other measures necessary for the purpose. We have considered as to the manner in which these two matters can best be submitted to the consideration of Parliament, and we are of opinion that they may very properly be included in the same measure, to be introduced as a private bill. We have accordingly given instructions to the agents to prepare the gazette notices and bill, and we recommend—

That the course taken be approved.

## LEGAL.

### Halifax and Bermuda Cable Company v. Magniac.—

This was an action to recover £3,968 and interest, balance of calls due on debentures of the company applied for by the defendant, which was tried on Tuesday before Mr. Justice Charles, without a jury.

Mr. Crump, Q.C., and Mr. Spokes appeared for the plaintiffs; Mr. Haughton for the defendant.

Mr. CRUMP said defendant applied for 50 debentures of £100 each, in May, 1889, and 49 were allotted him; he paid £500 on application and another £500 on allotment, but, applications for the balance being unattended to, after some difficulty an action

was commenced by substituted service, the defendant, being abroad, and judgment was signed against him. Afterwards, on the application of the defendant, the judgment was set aside, and a defence was put in to the effect that he had been induced to apply for the debentures by misrepresentation.

Mr. HAUGHTON said he need not trouble his friend to go into the case at length. The defendant had satisfied himself that the prospectus was issued *bonâ fide*, and negotiations had been going on with a view to his paying the whole amount due, and the company abandoning any claim for costs, which he understood was agreed to; but when the friend who had conducted the negotiations said he should like to have the debentures on paying over the money, it appeared that these very debentures which had been allotted to Mr. Magniac, and on the footing of which he was sued, had been deposited by the company as security for a loan, and the parties with whom they were pledged declined to release them on payment of the amount due on the calls, their claim being somewhat larger on account of interest. He asked, therefore, not making any objection to paying the amount, and even the costs, that the money might be paid into court or deposited with someone who would hand it over on receiving the debentures.

Mr. CRUMP said his friend was quite mistaken. When the defendant paid the money the debentures would be handed to him.

Mr. HAUGHTON asked leave to prove what he had stated, but

Mr. Justice CHARLES said such an issue was not raised on the pleadings. He must accept Mr. Crump's statement, and, as the only defence raised was abandoned, he must give judgment for the plaintiffs.

**Edison Electric Light Company v. Robertson.**—(Chancery Division.)—This was an action to restrain the defendant from further infringing the plaintiff's patents, for delivery up of the infringing lamps, and for costs.

Counsel for the plaintiffs moved for judgment in default of appearance for the defendant, and

His lordship made an order giving effect to the statement of claim.

## THE BRITISH INSULATED WIRE COMPANY.

UNDER this title a company has been formed for the purpose of working in this country the patents of the Norwich Insulated Wire Company of America, by which wires are insulated with paper. Mr. R. E. Crompton is the consulting engineer, which should be a guarantee that the processes, whatever they may be, are of value. The prospectus, however, does not furnish such information as would convince an expert that a really good thing has been produced; there is not one word that would indicate that if the insulated wire were submitted to the action of damp, or if soaked in water, its insulation would remain unimpaired. We are told that in New York the wire has been submitted to *the most searching test* of being laid close to the Steam Heating Company's mains. To call this a searching test is the height of absurdity; there are plenty of cables that will stand heat. Again, the electrical inspector of the Corporation of Liverpool is convinced that the cable is a good one—because it maintains a high insulation at a high temperature. As well might it be urged that the telegraph lines in India preserve their insulation in spite of the heat of the climate. Taking several other reports, we find that practically nothing more definite is stated than that the reporter "is convinced that the cables and wires are of a very superior kind." There is apparently no attempt to make any test which the merest tyro in a submarine cable factory would know to be necessary. We do not mean to condemn the wire; it may be a very good article both as regards efficiency and cheapness, but the practice (so common) of attracting the unsuspecting public by reports which are not worth the paper they are written on, cannot be too severely condemned.

**Siemens and Halske.**—A Vienna correspondent, under date of October 30th, informs us that the Anglo Bank is negotiating for the taking over of the electrical establishments which the Berlin firm of Siemens and Halske owns at Vienna, as well as the electric railway at Pesth belonging to that firm.

## NOTES.

**Croydon and the Electric Light.**—Mr. W. H. Preece, F.R.S., who has been consulted with reference to the introduction of the electric light into Croydon, which has been determined upon, has submitted an elaborate report, in which he states that it would be easy to establish a central station at the waterworks at the back of the Corporation offices, and from thence to generate and distribute sufficient electrical energy to serve the whole of the district. He proposes to replace the whole of 1,781 gas lamps by electricity. The provisional order which is to be applied for will include the whole borough; but it will only be compulsory to supply at first a fixed area, being the central portion of the town.

**The Electric Light at Southampton.**—The Southampton Electric Light and Power Company are now busily employed in laying their cables between the works in the Back-of-the-Walls and the Royal Southampton Yacht Club.

**Theatre Lighting in Bologna.**—The Brunetti Theatre, in Bologna, is now lighted by electricity. The prefectoral authorities, in order to ensure the safety of the public, informed the proprietors that they must either erect an iron curtain for the stage, or adopt the electric light, the latter alternative being eventually chosen. The plant comprises a steam engine and boiler of 14 N.H.P., and a compound Tecnomasio dynamo, running at 1,100 revolutions, with an output of 100 ampères at 100 volts. In addition to the glow lamps, the auditorium is lighted by three 10-ampère arc lamps, whilst a fourth arc is placed at the theatre entrance.

**Electric Lighting of the Guildhall.**—The Guildhall will be lighted by electricity for the first time on the occasion of the Lord Mayor's banquet on the 10th.

**Electric Lighting at Taunton.**—A gas contemporary calls attention to the fact that the electric lamps are having games. One evening last week the street arcs were out for about half an hour, and during the past two months the light has failed some half dozen times. Perhaps our electrical friends of this town may enlighten us on the subject.

**Theatre Lighting.**—Mr. Wilson Barrett will dispense with gas altogether behind the scenes of his new theatre, and use electric light.

**The Electric Light Area in Edinburgh.**—The compulsory area has been marked out, and the notices adjusted, in connection with the application for a provisional order.

**Harrogate Electric Lighting.**—It was decided at the last meeting of the Town Council to apply for a provisional order.

**Electric Lighting in Cardiff.**—The Council has decided to oppose all applications of private companies for lighting the town by electricity. It is proposed to keep it in its own hands, and land for this purpose will be purchased shortly.

**Electric Lighting at Brighton.**—On Tuesday, the Mayor of Brighton (Alderman Manwaring), laid the foundation stone of the Corporation electric generating station in North Road, Brighton. The Mayor expressed a hope that years to come would prove the wisdom of the decision of the Town Council. He was not prepared to say that at the first starting of the electric light installation it was going to be a financial success; but in the time to come, he thought they would find it was one of the wisest steps the Town Council had taken.

**Electric Light and Diving.**—On Monday last Mr. Applegarth exhibited, at 39, Queen Street, City, a greatly improved diving apparatus fitted with an incandescent lamp in the helmet. The object of the improvements is to reduce to a minimum the number of loose pieces completing the helmet, resulting in the saving of time and reduction of risk.

**Electrical Engineering Corporation.**—This corporation has just issued a remodelled and combined form of the catalogue hitherto published by the firms of J. G. Statter & Co., Limited, and their London agents, the United Electrical Engineering Company, Limited, owing to the interests of the two companies becoming one by the recently effected amalgamation of the two concerns. The manufactures of the company cover a wide range in electrical engineering, and the catalogue will be found very complete in regard to both descriptive matter and prices.

**W. T. Henley's Telegraph Works Company.**—A new price list has just been brought out by this company of electric light cables, and wires in vulcanised and unvulcanised India-rubber.

**Long Distance Telephony.**—A long distance telephone line is to be put in operation towards the end of the year between Coblenz and Cologne. A new telephone line between Vienna and Brünn was opened on the 1st inst. The wires are of bronze, and private subscribers in Vienna are able to communicate direct with those in Brünn.

**Newall High-Speed Engine.**—Messrs. G. Wailes and Co. give notice that they are manufacturing the above with improvements which give remarkably increased efficiency. The engine will in future be known as the Lord-Newall high-speed engine. It is made high-pressure, compound triple expansion, quadruple, and launch.

**Kingston-on-Thames Electric Lighting.**—The Board of Trade will be petitioned for a provisional order by the Local Authorities.

**Explosion in Junction Boxes.**—An accumulation of gas in a junction box in one of the principal thoroughfares in Newcastle caused an explosion last Thursday. Three or four persons were knocked down, but no one was seriously hurt.

**Subways for Pipes and Mains.**—A proposal has emanated from the Strand District Board to introduce a Bill into Parliament dealing with the subject of subways for electric light mains.

**M. Secretan.**—A financial contemporary writes:—"To have secured M. Eugene Secretan as manager is a great stroke for Elmore's French Patent Copper Depositing Company. Despite his misfortunes, M. Secretan's name is still one to conjure with, for there is no doubt that he knows copper in all its branches. But we would warn the directors and shareholders against being too greatly impressed by the fact that M. Secretan is a 'firm believer in the Elmore process,' and by his belief that 'the scope for the operations of the company is far more extensive than they had originally calculated upon.' The magnitude of his ideas is a rock on which M. Secretan has foundered before. At the same time he is a very valuable acquisition, and when the company does get seriously to work, of which there is now a prospect, no doubt he may in a practical capacity to some extent retrieve the reputation and fortunes shattered by the collapse of the last copper enterprise, in which he was 'a firm believer.'" To this we might add, that the man who was responsible for the liquidation of a *Comptoir d'Escompte*, ought to find his position on an Elmore Copper Company easy work.

**French Elmore.**—The following appeared in the *Echo* of Tuesday:—"We have no doubt but that the directors of the French Elmore Copper Company are acting in the interests of their shareholders in sanctioning an issue of £50,000 of debentures in order to carry out the views of M. Secretan. It certainly appears as though this discovery as to the inadequacy of the working capital might have been made a few weeks sooner; but, be this as it may, we think the shareholders might naturally expect the board to raise the required sum at *something* under  $7\frac{3}{4}$  per cent. The money is to be raised by the issue of £50,000 debenture stock at par, redeemable on November 1st, 1893, at 105. Thus, in addition to the high rate of interest (6 per cent.), £5 per cent. is to be paid at the end of three years, or an extra £1 13s. 4d. per annum. "Your directors have much pleasure in announcing that the patent company, Elmore's Foreign and Colonial Patent Copper Depositing Company, Limited, has offered to supply the amount required by subscribing for £50,000 six per cent. debenture stock at par, redeemable at £105 on the 1st November, 1893." In other words, the directors consider themselves lucky to be able to raise the money at the rate of £7 13s. 4d. per cent. upon a first mortgage security. Instead of "having much pleasure" in making this announcement, we should have fancied that, to pay so high a rate upon so good a security, was a subject for extreme regret. This rate, indeed, is a very serious reflection upon the security, as the opinion of no lenders can be more valuable than that of the parent company. They, more than anyone, know the nature of the security; and it is not, therefore, a compliment to it that  $7\frac{3}{4}$  per cent. is demanded. Of course there may be reasons unknown to us why the offer of the parent company should be accepted, and, provided the shareholders of the French Elmore Company are willing to pay it, no one else has a right to complain. It merely strikes us, as onlookers in the interests of the public, that if the money be required, it might be raised at something under this high rate. From the merits and prospects of the French Elmore Company, and from M. Secretan's opinions, we should have expected that even seven per cent. preference shares could have been issued at par, and redeemable in 1895; instead of which, *over*  $7\frac{1}{2}$  per cent. is being paid upon a debenture security.

**New Insulating Wire Cleat.**—The illustration will fully convey to our readers the novelty and utility of the new "celluvert" or kartavert fibre insulating cleat, now being introduced into this country by Messrs. David Moseley and Sons, of Ardwick, Manchester. It is largely used in America for telegraph, telephone,

electric light, and electric bell *inside* wiring, and answers the purpose admirably, as it is very handy, strong, light, and cheap. Unlike other cleats or staples, it cannot be shattered by an ill-directed blow of a workman's hammer when fastening down with nails or tacks. They are made for single or double wires, but it will be seen that by cutting the double cleat across it will answer for one wire.

**Semaphore Telegraphs.**—In our next we shall be able to illustrate, thanks to the kindness of a friend, a semaphore telegraph, such as a correspondent in our last issue desired to see.

**Provisional Orders.**—The towns of Hexham and Heckmondwike are applying for orders.

**Electrical Trades' Section.**—A meeting of the committee will be held at Botolph House, on Monday, at 4 p.m., when various subjects will be brought forward for discussion.

**Coloured Insulators.**—The overhead lines of the Belgian telegraph and telephone systems follow, in a very great number of cases, unfrequented roads and by-ways where supervision is, naturally, not very close. The wilful destruction of porcelain insulators on these lines assumed such proportions that the Government has been obliged to seriously consider the question of preserving them. A special insulator, protected with a shield of galvanised cast iron, was devised, but it was found that these insulators were far too heavy, and their cost too great; they were therefore abandoned. It would seem that the brilliantly white colour of the porcelain insulators formed the chief attraction to mischievously inclined persons who, unable to resist these fatally conspicuous objects, converted the insulators into impromptu targets. Experiments were consequently made with porcelain of various colours, and a greyish-brown was finally decided upon. Several hundred insulators, coloured in this shade by means of a silicate mixed with the enamel on the surface of the porcelain, were ordered, and were set up alternately with white porcelain insulators. The results of a year's trial showed that out of 102 insulators of each kind (white and coloured) on a line of 22 kilometres in length, 25 ordinary insulators were broken, while only 13 of the coloured ones had been damaged. It was in consequence decided that wherever a white insulator was found to have been wilfully destroyed, a coloured one should be set up in its place, and should this, in its turn be broken, a metal-protected one would be substituted.

**The Spanish-African Cables.**—In commenting upon the failure of the first invitations to tender for the proposed cables between the Spanish settlements on the Mediterranean coast of Morocco, the *Ciencia Eléctrica*, of Madrid, in a recent issue, contained an article strongly condemning the Spanish Administration for its procedure. It pointed out that the conditions laid down by the Administration were utterly impracticable, and that the fact of only two tenders being received confirmed this argument, the more so since neither of the tenders complied with the stipulations of the decree. The Administration was severely blamed, in the first place, for having fixed the price to be paid for the cable at far too low a figure, and, secondly, for not having accepted one or other of the tenders, which after all did not greatly exceed the stipulated figure; nor did these offers ask for conditions at all detrimental to Spanish interests; on the contrary, the compensations asked for in other directions might actually prove advantageous to the country. The disappointment felt in Spain at the failure to secure these long desired telegraphic communications seems to have been very keen, and a perfect storm of indignation appears to have been aroused, perhaps unjustly, against the Administration.

**The ss. "Silvertown."**—News has been received that this cable ship passed Rio de Janeiro on November 4th and reported "all well."

**Personal.**—Mr. Magnus Volk having completed the fitting out of the fleet of electric launches on the river Thames, belonging to the General Electric Power and Traction Company (late Messrs. Immisch & Co.), his connection with the company has terminated, and he is now completing some new types of electrical measuring instruments which are said to possess many novel features.

**The First Atlantic Cable.**—Mr. F. C. Webb, of 27, Forest Road, Dalston, N.E., has published a chart which gives the longitudinal sections of H.M.S. *Agamemnon* and the United States frigate *Niagara*, and the position of the coils of cable, with the lengths in nautical miles, used on the expedition of 1858, when the first Atlantic cable was laid. We understand it may be obtained from Mr. Potters, the agent for the Admiralty charts, Poultry, E.C.

**The Institution of Electrical Engineers.**—On Thursday, November 13th, 1890, there will be a Council meeting at 7 p.m., and an ordinary general meeting at 8 p.m., when the following paper will be read: "On the Chemistry of Secondary Cells," by Prof. W. E. Ayrton, F.R.S., Vice-President; C. G. Lamb, B.Sc.; and E. W. Smith, associates. The above paper will be discussed together with that on "The Working Efficiency of Secondary Cells," by the same authors, which was read at the Edinburgh meeting on July 16th.

**More Newspaper Science.**—The *Daily Telegraph*, on Tuesday, devoted a column to an article on the City and South London Railway. The following is an excellent specimen of the whole:—"Not only does Electra run on messages for us with the very speed of the obedient Puck, who at his fairy lord's command was ready and willing to 'put a girdle round about the earth in 40 minutes,' but she bravely submits to be 'accumulated' and stored up in darkness until such time as we desire light, and then we switch her on, and she leaps into the crystal vacuum and glows with cheerful splendour as she circles round the tiny film of platinum. She is not too proud to ring a bell if required, and if needs be is prepared to carry our very voices through the roar and din of the city, so that man can talk to his fellow at a distance, or minute by minute unfolds on the clicking tape the passing events of all the earth; indeed, like the German school of metaphysics, she almost fairly succeeds in abolishing time and space even as 'forms of the understanding.' Swifter than Iris, the messenger of the gods, our gentle handmaiden has never shirked any task entrusted to her; and if, perhaps, she naturally bungled a bit when set to do the ugly work of a public executioner, her growing stern sense of duty and devotion to mankind may in time steady her hand as the ultimate minister of the death-sentence. Meanwhile, it is pleasant and comforting to record that under Royal auspices she will make her *début* in London this week as an underground traveller."

**Award.**—A gold medal has been awarded to Messrs. Lacombe & Co. for their carbon exhibit in the French electrical section of the Edinburgh Exhibition.

**St. Pancras Electric Light.**—The ceremony of laying the first stone of a central station in Stanhope Street took place on Tuesday last. After the formal business Prof. Henry Robinson (the electrical engineer to the vestry) made a statement as to the work they intended to do. At Stanhope Street the central station plant would be capable of supplying low tension current to serve 10,000 incandescent lamps of 16 C.P. simultaneously, and at the same time high tension current to serve 90 10-ampère arc lamps. There would be nine low tension and two high tension dynamos, one of each serving as reserve. We understand that orders have been received for all the available current on this station. Great energy has been displayed by the vestry committee, and we heartily wish them success in their undertaking.

**Ship Lighting.**—Last week there was launched from the shipbuilding yard of Messrs. Barclay, Earle & Co., Limited, Whiteinch, a steel screw steamer, the *Lismore Castle*, for the Castle Mail Packet Company, Limited. She is fitted throughout with the electric light, &c.

On Tuesday the British India Company's steamer *Amra* ran her official trial on the Clyde, when a mean speed of 12·8 knots was obtained, notwithstanding that the weather was stormy. The *Amra* is fitted throughout with the electric light.

**Personal.**—Mr. A. W. Jones has resigned the post of Chief Electrician to the Exeter Electric Light Company, Exeter, and has joined the Laing, Wharton and Down Construction Syndicate.

**Electricity in the French Navy.**—A telegram from Brest states that the Minister of Marine has decided that every military port shall send to Paris two foremen and two working electricians to study the various systems of electric lighting. Lectures upon the theory and use of electricity and its employment for naval purposes will commence at the Observatory here on the 11th inst., and will be continued for four months.

**A Correction.**—A friend writes:—"I have just seen in the ELECTRICAL REVIEW of last week a paragraph copied from a Madrid paper, called *Los Anales de la Electricidad*, and saying that we intend to work Ferranti machines at 10,000 volts here. The machines are Ferranti's, but 2,400 volts, not 10,000, a slight difference. The underground cables are of the best Silver-town make, and the same as are being, and have been used in London for some time. I know you will be good enough just to mention the error in your next issue, as it may frighten some of our friends here if they saw it."

**Vienna Telephones.**—It is thought probable that the management of the Vienna telephones will be taken over by the State. The International Postal Congress will assemble at Vienna on May 20th, 1891.

**The Royal Institute of British Architects.**—At a meeting held at the Royal Institute of British Architects on Monday, the 3rd instant, the council room of the Institute was lit by electric light. The electric light installation is being carried out by the Planet Electrical Engineering Company, and, for the evening, a temporary connection was made with accumulators in the council room. The lighting gave satisfaction to the members of the Institute who were present.

**Electricity is (Indirectly) Life!**—Says the *Financial News* of yesterday:—"When the Prince of Wales opened the electric railway from the Monument to Stockwell, he may have thought that the utility of the work was limited to increasing the convenience of traffic. He was mistaken, as Sir John Fowler took the liberty of reminding His Royal Highness. So pure is to be the air in these electric tunnels, that Sir John, with his keen engineer's eye, can see a day in which doctors will send their suffering patients to the lower realms—not in the old, accustomed way, but to mend impaired health in an atmosphere more salubrious than on earth—on London earth, that is. We advance indeed. Fancy an asthma patient prescribed a course of the Inner Circle!"

**The Electric Light at Barnet.**—A gas contemporary says: More complaint has been made by the Barnet Local Board of the deficient lighting furnished by the electric lamps, and the contractor (Mr. Joel) has been again remonstrated with on the subject. At the last meeting of the board his reply was received, and its reading caused much amusement. He said he had ordered a number of 32 candle-power lamps for use at Barnet, but that the maker had sent 50 candle lamps instead, so that the district was actually being lighted by 32 and 50 candle-power lamps. When the mirth which this statement produced had subsided, a proposition was brought forward that the thanks of the board should be given to the contractor for his generosity. But this did not find a seconder; probably from the fact that it was regarded as sarcasm. A member asked the Clerk if his eyes had not played him false, causing him to read 50 for 15. The Clerk replied that the figure was 50. In the whole history of this extraordinary lighting undertaking, nothing has equalled this. As the local paper remarks, "The wildest dreams of the most enthusiastic resident never suggested a ray in excess of the contract light; so the Barnet Local Board may be pardoned a little surprise at the revelation."

**Dangers of the Electric Light.**—According to the *West Middlesex Advertiser*, the landlord and employes of the Markham Arms are not likely to forget the night of Monday, October 20th, 1890. The experience they then underwent, while certainly of a novel was yet of an alarming character. Late in the evening, just previous to turning out the lights, something unusual was noticed to be the matter with the electric incandescent lamps. Mr. Dew rushed to the switch and turned it off, but not before the lamps which were attached to the three large gas chandeliers in the bar were smashed to pieces, and great streaks of fire over a yard long had been streaming from the tubes, to which the platinum wire had been fastened, previous to its being broken and carried away with the globe. The box by the side of the switch was burned. Great damage was done both up and down stairs. It should be stated that at the Markham Arms is a most thorough installation of the electric light; this form of illumination being used in every part of the house. Mr. Dew, the housekeeper, and others residing on the premises, are at a loss to know the cause of the fire, and they state that if the enormous pressure of electricity had been kept up half a minute later, or if Mr. Dew had not turned the switch when he did, nothing could have saved the house from being destroyed by fire. "Three of us were standing in the bar at the time," remarked the housekeeper to our representative, "and it was an awful sight; I prefer the old gas to this, it's much safer." The electric supply at the Markham Arms was laid on by the Cadogan Electric Company, Manor Street.

**Telephony in France.**—According to the *Figaro*, the following towns are telephonically connected with Paris:—Lille, Rouen, Le Havre, Elbeuf, Rheims, Lyons, and Marseilles, whilst the line to Brussels is the longest. There are also connected with Paris:—Amiens-Arras-Lille, Saint Quentin, Paris-Orleans, Paris-Troyes, and it is proposed to further extend the telephone service with Epinal as the centre. There are 8,000 subscribers in Paris, 1,800 of whom have joined this year, whilst in the provinces the total is 6,000. The whole service is summed up as 22 distributing networks in Paris and district, 50 local installations, of which two are in Algiers, 20 connections with other towns, and 12 for long-distance telephony.

**The "Peral."**—The latest news from Spain with regard to the unfortunate *Peral*, which, after all, seems to be neither fish, flesh, fowl, nor good red herring, is to the effect that the Supreme Naval Council confirms the decision of the Technical Commission held at Cadiz; but while affirming that no new idea has been originated in the construction, and that no practical use can be made of the fabric, the Supreme Council authorises Lieut. Peral to continue his experiments on a new scheme. By this decision, the Supreme Council, says the Madrid Press, has acquired the rare distinction of having surprised the whole world.

**Electricity Superseded.**—Jules Verne, whose romances were at one time ridiculed, has lived to see some of them almost realised; but he will now have to take a back seat. Mr. Weems's system of electric traction, and the portelectric system, are also put in the shade by the high-sounding Mount Carmel Aeronautic Navigation Company, who propose to run air ships carrying passenger cars the size of Pullman cars. The ships will be built of aluminium, and are to travel through the air at a terrific speed. Mails will be dropped from the ships into mail bags below, as they scud through the rarefied atmosphere.

**The Paris-London Telephone.**—It is announced in Paris that telephonic communication between that city and London will be opened on January 1st.

**The Progress of Electrical Firms.**—Our contemporary *Money* devotes considerable space to the rise of Messrs. Laurance, Scott and Company, Limited. Commencing seven years ago as a private concern, electrical apparatus was manufactured in a small way. Gradually growing, and becoming limited in a company sense, the business has assumed proportions which few companies equal and fewer surpass. The dynamo room is at present full of orders, among others being an important one from the Chelsea Electricity Supply Company. Under its auspices a local company has been floated, which will doubtless supply current to the town. A central station is already supplying light to the works and the principal places around.

### NEW COMPANIES REGISTERED.

**Llangammarch Estate and Land Company, Limited.**—Capital £100,000 in £10 shares. Objects: To acquire lands and buildings in the county of Brecon, or elsewhere, and particularly the Tyncoed Farm, parish of Llanlleonfel, and to carry on building operations. To construct, work and manage electric power, heat and light supply works, telephone and other works. Signatories (with 10 shares each): H. Watkin Lewis, Merthyr Tydvil; D. T. Alexander, Cardiff; R. A. Bowring, Penarth; C. J. Jackson, Cardiff; J. Wesley Courtes, Cardiff; Lascelles Carr, Tredelerch near Cardiff; J. E. Gunn, Cardiff; M. Tennant, Aberavon. Directors' qualification, £100 in shares or stock; the company in general meeting will determine remuneration. Registered 30th ult. by A. H. Atkins, agent for Tennant and Jones, Aberavon.

**Electrical Supplies and Fittings Company, Limited.**—Capital £20,000 in £5 shares. Objects: To carry on in the United Kingdom the business of electricians and mechanical engineers, and in particular to construct, purchase, sell, establish, fix and maintain all necessary motors, cables, wires, accumulators, insulators, lamps, electroliers, &c. Signatories (with one share each): J. L. A. Rooke (electrical engineer), 14, Keppel Street, W.C.; J. N. Roxburgh, 77, Queen's Road, Finsbury Park; J. Whitehead (electrical engineer), Haycot, Crouch End; F. B. Arundell, 1, Devonshire Street, Portland Place; W. L. Madgen, 3, Princes Mansions, Victoria Street; N. G. Bingham, C.E., 29, Notting Hill Terrace; G. E. Butler, 15, Park Hill, Sydenham. The signatories are to appoint the first director, qualification, £200 in share capital, remuneration £500 per annum, together with one-tenth of the net profits remaining after payment of 8 per cent. dividend on the ordinary share capital, but not to exceed £1,000 per annum. Registered 31st ult., by Wilson, Bristows & Carpmal, 1, Copthall Buildings.

**United Alkali Company, Limited.**—Capital, £6,000,000 in £10 shares. Objects: To manufacture chemical products and drugs of all kinds. To carry on business as metallurgists in all branches, and also as waterproofer and India-rubber and leather manufacturers. To carry on any business, or businesses, directly or indirectly connected with the generation, accumulation, distribution, supply or application of electricity. Signatories (with 1 share each), \*John Brock; H. Gaskell, Widnes; J. K. Huntley, Flint; \*Chas. Wigg, J. Dennis and \*E. K. Muspratt, Liverpool; \*A. W. Allhausen; \*J. Tennant, Gateshead; \*J. C. Davidson, Newcastle; \*C. E. Barlow; \*H. Gaskell, Jr.; \*Robert Shaw, Widnes; \*J. C. Stevenson, M.P., South Shields; \*G. L. Wigg, Runcorn; \*P. J. Worsley, Bristol; \*J. A. E. Rayner, \*W. J. Menzies, Widnes. The signatories and Thomas Alexander, E. Baxter and J. Gaskell are the first directors; qualification, £1,000 in shares or stock; remuneration, chairman, £2,500 per annum, with an additional £500 per annum in each year in which at least 8 per cent. is paid on the ordinary shares; the other directors will be remunerated at the rate of £400 per annum each. Registered 1st inst. by H. Forshaw and Hawkins, of 5, Castle Street, Liverpool.

### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**South Staffordshire Electric Lighting Company, Limited.**—The annual return of this company, made up to the 30th ult., was filed on the 31st ult. The nominal capital is £100,000, in £5 shares; 139 shares are taken up, and the full amount has been called thereon. The calls paid amount to £690, and unpaid to £5.

**Head, Wrightson & Co., Limited** (engineers, electricians, &c.).—The statutory return of this company, made up to the 7th ult., was filed on the 18th ult. The nominal capital is £210,000, in £5 shares, the whole of which are taken up, 13,999 shares being considered as fully paid. The calls received amount to £140,005.

An extraordinary meeting of the company was held on the 23rd September, when it was resolved that the following be substituted for Clause 19 of the articles of association:—

"The directors may, subject to the regulations of these presents, from time to time make such calls upon the shareholders in respect of all moneys unpaid on their shares as they think fit, provided that 21 days' notice at least is given of each call, and that no call in respect of any share shall exceed one-fourth of the nominal amount of such share, or be made payable within two months after the last preceding call was payable, and each shareholder shall be liable to pay the amount of every call so made upon him to the persons and at the times and places appointed by the directors." This resolution was confirmed on the 8th ult., and filed 15th ult.

**Dick Kerr and Company, Limited** (engineers and electricians).—The statutory return of this company, made up to the 9th ult., was filed on the 17th ult. The nominal capital is £160,000, in £5 shares, the whole of which are taken up, one half being considered as fully paid. The remaining capital is also paid up.

**New Electric Fire Lighter Company, Limited.**—The statutory return of this company is made up to the 28th ult. The nominal capital is £10,000, in £1 shares. 602 shares are taken up, and the full amount has been called thereon. The calls paid amount to £500, and unpaid to £102.

### CITY NOTES, REPORTS, MEETINGS, &c.

#### Westminster Electric Supply Corporation, Limited.

THE report presented at the meeting held on Wednesday states the affairs of the corporation are proceeding in a rapid and satisfactory manner.

The first work which claimed their attention, after the allotment of the shares, was that of obtaining suitable sites for central stations, three of which were required for the supply of the district which had been allotted to the corporation.

In January last the board acquired the undertaking of the City of Westminster Electrical Syndicate, Limited, who had commenced business in the district, and thereby obtained possession of St. John's Wharf, Millbank Street, and also of the contract for electric lighting in the Houses of Parliament.

After considerable trouble and delay, the board succeeded in obtaining two other eligible sites—one in Eccleston Place, Belgravia, and the other in Davies Street, Mayfair, both being on the Duke of Westminster's estate.

Pending the installation of the large central stations, current has been supplied from two temporary stations—one in the stone-yard adjacent to the Houses of Parliament and the other in Dacre Street, Victoria Street. By means of these temporary stations, the nucleus of a good business has been formed, and at the present time current is being supplied from underground mains equivalent to about 6,000 8-C.P. lamps on circuit. The demand for current already far exceeds the amount which can be generated from the plant in actual work, but the new station at St. John's Wharf is now running, and able to take over the work in the Westminster District and allow the Dacre Street plant to supply as far as Belgrave Square, pending the completion of the Eccleston Place Station.

The installations in Mayfair and Belgravia are rapidly advancing; the mains have been laid in many of the principal streets, and are being laid as quickly as possible in the others, and

the Board hope that current will be supplied from both these stations early in the New Year.

The board have ordered plant (viz., engines, boilers, dynamos, batteries, &c.) to the amount of about 2,600 indicated horsepower for the three stations, a large part of which has already been delivered. This will be sufficient to supply about 40,000 8-C.P. lamps alight at one time, allowing an ample margin for steam power in reserve. According to present experience this will correspond to upwards of 100,000 8-C.P. lamps on circuit.

The system of distribution adopted is the low tension continuous current. The mains already laid are shown on maps, which can be seen at the corporation's offices, and amount in all to nearly 11 miles, and permission has already been obtained from the authorities for the whole system of proposed mains.

The financial year ends on the 31st December, and the accounts will be made up and audited to that date, and the board recommend that in future the annual general meeting of the shareholders should be held in the month of February, when the accounts would be ready for presentation.

Lord Suffield (the chairman) said great progress had been made with their works, as indicated by the maps. There had been completed nearly 11½ miles of mains. He congratulated them on the progress made. The Millbank Street Station was in working order, and he considered they were greatly indebted to their chief engineer (Prof. Kennedy), who had shown great energy in carrying out the work. The other stations were in a fair condition, excavation was proceeding at the Davies Street Station. It was satisfactory to know that all the engines and machinery were ready whenever they were ready to receive it. In answer to various shareholders, he said the applications for current were very numerous, and were coming in every day. They could not, of course, supply these demands, but he hoped by the early part of the year they would supply all that would be required. When they would be able to pay a dividend he could not say. Expenses were very heavy, and it would be necessary to call up the whole of the capital shortly. With regard to the question of monopoly, in some parts of the district they were running side by side with another company, but in other parts they were alone. There would certainly be rivalry, and it was necessary that they made their system as near perfection as possible.

Mr. Scott (a shareholder) spoke in very favourable terms of the works which he had seen only recently. He recommended that a further remuneration should be given to the directors.

In reply to questions on the estimates, Prof. Kennedy said they were well within the stated sums.

The meeting terminated with a vote of thanks to the board.

### Montevideo Telephone Company.

At the meeting held on Friday last, the Chairman (Mr. Holland) said the report was not as satisfactory as they desired, and certainly not in accord with the indications held out at the last meeting, and at the meetings where they were asked to increase the capital of the company, for the purpose of multiple switchboards and other improvements. It was, however, satisfactory in the respect of profits, for, as shown in the report, it was about equal to that of last year, and this time they had passed through a period of great depression, which was felt both at Montevideo and Buenos Ayres. Although telephones in many cases were articles of necessity, they were in many others articles of luxury and convenience, and when there came a time in which it was imperative for customers to exercise economy, the tendency was to dispense with the telephones. The company had suffered a great deal in this way, and many withdrawals had resulted from the stagnant state of business in Montevideo. On the other hand, owing to the improvements which the shareholders sanctioned some time ago, they had a considerable number of new shareholders to take the place of those who had withdrawn, consequently they were financially about in the same position as last year. They had deducted from the profits small expenses for preliminary and depreciation on furniture; this would be written off in a few years. They would propose a full dividend of 6 per cent. on the preference shares, and to carry £1,000 to depreciation fund, and another £1,000 to reserve fund, because, in the present state of things, they deemed it prudent to have a substantial reserve. He continued to hope that when the wave of depression had passed, they would receive full benefit of all the money they had spent out there. As stated in the report, they had spent a considerable sum in extending wires and cables to new subscribers. Under the head of profit and loss there was an increase in the subscriptions of £891, on the other hand there was an increase in the expenditure of £1,130, owing to extra taxes which they had been called upon to pay, and also on account of extra insurance. Expenses in London were a little higher, owing to the fact that in the previous 12 months they had received a little consideration from the company, for whom they turned out of their old offices. Expenses in Montevideo amounted to 48 per cent. of their receipts; this compared very favourably with the telephone company on the other side of the river, whose expenses were 61 per cent. of the receipts. It showed that on their part there had been good management. He considered that the ordinary stock of the company would before long be very valuable property. Had there been no withdrawals and the same influx of new subscribers they could have paid their ordinary shareholders 6 per cent. In conclusion, he moved the adoption of the report and accounts.

Mr. T. D. Peters seconded, and the motion was carried unanimously.

The resolution as to the dividend was then put to the meeting and carried.

The Chairman moved, and Mr. E. F. Powers seconded, that the retiring director, Mr. Peters, be re-elected a director, which was done.

The auditors, Messrs. Gérard Van de Linde and Son, were re-elected at a remuneration of 20 guineas.

The meeting then terminated.

### The West India and Panama Telegraph Company, Limited.

THE directors submit the accounts for the six months ended 30th June, 1890. The amount to credit of revenue is £52,351 2s. 4d. (against £49,985 11s. 9d. for the corresponding half-year of 1889), and the expenses have been £26,669 17s. 4d. (against £24,458 6s. 9d. for the same period in 1889), leaving a balance of £25,681 5s., which, with the balance of £516 19s. 8d. brought from last account, makes a total of £26,198 4s. 8d. Of this sum the directors have placed £1,500 to reserve, leaving an available balance of £24,698 4s. 8d., with which it is proposed to deal as follows:—

	£	s.	d.
First preference shares—			
Dividend, 6 months to 30th June, 6s.			
per share ... ..	10,368	18	0
Second preference shares—			
On account of arrears of dividend to			
30th June, £3 per share ... ..	14,007	0	0
Balance to current half year's account ... ..	322	6	8
	£24,698	4	8

The traffic receipts for the six months show an increase of £2,779 7s., as compared with the corresponding period.

Several interruptions to the cables occurred during the half-year, and the expenses for repairs amount to £13,936 8s. 3d., being £2,900 19s. 11d. more than those for the corresponding six months.

The shareholders will remember that at the time of the last general meeting, negotiations were in progress with the Government of Barbados to lay a second cable to that colony in consideration of the continuance of the subsidy of £2,500 per annum for a period of 10 years. The necessary Act having been passed, the new cable was successfully laid between Barbados and St. Vincent in July last.

In consequence of the laying of the new lines above referred to out of the stock of cable in the West Indies, it has become necessary to replenish that stock for repairing purposes, and a contract has been entered into with Siemens Brothers and Company, Limited, for the manufacture of 215 knots of cable, which will be conveyed to the West Indies in the company's steamship, *Grappler*, which arrived in the Thames on the 21st inst.

The Danish colonies of St. Thomas and St. Croix have renewed their subsidies for a further term of five years from the 31st December last.

**Western and Brazilian Telegraph Company.**—The directors propose, after placing £7,500 to the renewal fund and £5,880 to the debenture redemption fund, a dividend at the rate of 4 per cent. per annum for the six months ending June 30th, last.

**Middlesborough Electric Light Company.**—Certificates were ready on Monday and will be exchanged for bankers receipts at the London office, Blomfield House, New Broad Street, E.C.

### TRAFFIC RECEIPTS

The Brazilian Submarine Telegraph Company, Limited. The traffic receipts for the week ending October 31st were £5,411.

The Cuba Submarine Telegraph Company, Limited. The estimated traffic receipts for the month of October were £3,200 as compared with £2,903 in the corresponding month of last year. The receipts for the month of July, estimated at £3,150, realised £3,134.

The Direct Spanish Telegraph Company, Limited. The estimated receipts for the month of October show an increase of £154 as compared with the corresponding period.

The Eastern Extension, Australasia and China Telegraph Company, Limited. The receipts for the month of October, 1890, amounted to £47,117, as against £45,679 in the corresponding period, an increase of £1,438.

The Eastern Telegraph Company, Limited. The receipts for the month of October were £39,589, as against £32,981 for the same period of 1889, or a decrease of £3,392.

The Great Northern Telegraph Company, Limited. The receipts for the month of October amounted to £28,000; 1st January—31st October 1890, £232,800; corresponding months 1889, £229,200; do. 1888, £226,200.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending October 31st, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £4,235.

The West Coast of America Telegraph Company, Limited. The gross earnings for the month of October, 1890, were £3,800.

The West India and Panama Telegraph Company. The receipts for the half-month ended October 31st, are £2,910, as compared with £2,735 in the corresponding period of 1889.

## THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.

(Continued from page 536.)

On examining the numbers in detail we observe that the largest number of magnetic lines forced round the bend of the iron core, through the coil *c*, was 24,040 (the cross section being a little over 1 square centimetre), which was when the armature was in contact. When the armature was away, the same magnetising power only evoked 9,795 lines. Further, of those 24,040, 23,660 (or 98½ per

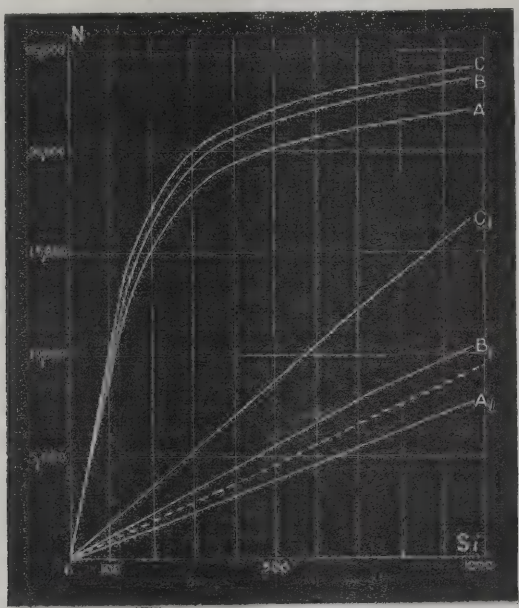

FIG. 44.—CURVES OF MAGNETISATION PLOTTED FROM PRECEDING.

cent.) came up through the polar surfaces of contact, and of those again 21,980 (or 92½ per cent. of the whole number) passed through the armature. There was leakage, then, even when the armature was in contact, but it amounted to only 7½ per cent. Now, when the armature was moved but 1 millimetre (i.e.,  $\frac{1}{32}$ th inch) away, the presence of the air-gaps had this great effect, that the total magnetic flux was at once choked down from 24,040 to 17,220. Of that number only 10,810 (or 61 per cent.) reached the polar surfaces, and only 8,110 (or 47 per cent. of the total number) succeeded in going through the armature. The leakage in this case was 53 per cent. ! With a 2 millimetre gap, the leakage was 65 per cent. when the strongest current was used. It was 68 per cent. with a 5 millimetre gap, and 80 per cent. with a 10 millimetre gap. It will further be noticed that whilst a current of 0.7 ampère sufficed to send 12,506 lines through the armature when it was in contact, a current 8 times as strong could only succeed in sending 8,110 lines when the armature was distant by a single millimetre.

Such an enormous diminution in the magnetic flux through the armature consequent upon the increased reluctance and increased leakage occasioned by the presence of the air-gaps, proves how great is the reluctance offered by air, and how essential it is to have some practical rules for calculating reluctances and estimating leakages to guide us in designing electro-magnets to do any given duty.

The calculation of magnetic reluctances of definite portions of a given material are now comparatively easy, and, thanks to the formulæ of Professor Forbes, it is now possible in certain cases to estimate leakages. Of these methods of calculation an abstract will be given in the appendix to this lecture. I have, however, found Forbes's rules, which were intended to aid the design of dynamo machines, not very convenient for the common cases of electro-magnets, and have therefore cast about to discover some more apposite mode of calculation. To predetermine the probable percentage of leakage one must first distinguish between those magnetic lines which go usefully through the armature (and help to pull it) and those which go astray through the surrounding air and are wasted so far as any pull is concerned. Having set up this distinction, one then needs to know the relative magnetic conductance, or permeance, along the path of the useful lines and that along the innumerable paths of the wasted lines of the stray field. For (as every electrician accustomed to the problems of shunt circuits will recognise) the quantity of lines that go respectively along the useful and wasteful paths will be directly proportional to the conductances (or permeances) along those paths, or will be inversely proportional to the respective resistances along those paths. It is customary in electro-magnetic calcula-

tions to employ a certain coefficient of allowance for leakage, the symbol of which is *v*, such that when we know the number of magnetic lines that are wanted to go through the armature we must allow for *v* times as many in the magnet core. Now, if *u* represents permeance along the useful path, and *w* the permeance of all the waste paths along the stray field, the total flux will be the useful flux as *u + w* is to *u*. Hence the coefficient of allowance for leakage *v*, is equal to *u + w* divided by *u*. The only real difficulty is to calculate *u* and *w*. In general *u* is easily calculated, it is the reciprocal of the sum of all the magnetic reluctances along the useful path from pole to pole. In the case of the electro-magnet used in the experiments last described, the magnetic reluctances along the useful path are three in number, that of the iron of the armature, and those of the two air-gaps. The following formula is applicable,

$$\text{reluctance} = \frac{l_1}{A_1 \mu_1} + \frac{2 l_2}{A_2},$$

if the data are specified in centimetre measure; the suffixes 1 and 2 relating respectively to the iron and to the air. If the data are specified in inch measures the formula becomes

$$\text{reluctance} = 0.3132 \left\{ \frac{l'_1}{A'_1 \mu_1} + \frac{2 l'_2}{A'_2} \right\}$$

But it is not so easy to calculate the reluctance (or its reciprocal, the permeance) for the waste lines of the stray field, because the paths of the magnetic lines spread out so extraordinarily and bend round in curves from pole to pole.

Fig. 45 gives a very fair representation of the spreading of the lines of the stray field that leaks across between the two limbs of a horse-shoes electro-magnet made of round iron. And for square iron the flow is much the same, except that it is concentrated a little by the corners of the metal. Forbes's rules do not help us here. We want a new mode of considering the subject.

The problems of flow, whether of heat, electricity, or of magnetism, in space of three dimensions, are not amongst the most easy of geometrical exercises. However, some of them have been worked out, and may be made applicable to our present need. Consider, for example, the electrical problem of finding the resistance which an indefinitely extended liquid (say a solution of sulphate of copper of given density) offers when acting as a conductor of electric currents flowing across between two indefinitely long parallel cylinders of copper. Fig. 45 may be regarded as

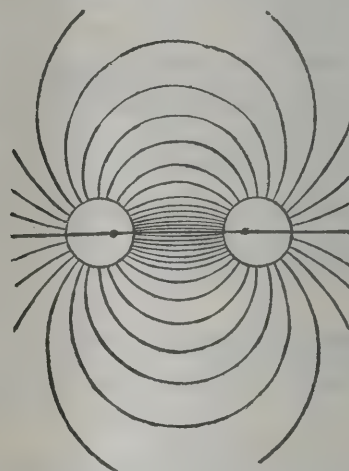

FIG. 45.—CURVES OF FLOW OF MAGNETIC LINES IN AIR FROM ONE CYLINDRICAL POLE TO ANOTHER.

representing a transverse section of such an arrangement, the sweeping curves representing lines of flow of current. In a simple case like this it is possible to find an accurate expression for the resistance (or for the conductance) of a layer or stratum of unit thickness. It depends on the diameters of the cylinders, on their distance apart, and on the specific conductivity of the medium. It is not by any means proportional to the distance between them, being, in fact, almost independent of the distance, if that is greater than twenty times the perimeter of either cylinder. Neither is it even approximately proportional to the perimeter of the cylinders except in those cases when the shortest distance between them is less than a tenth part of the perimeter of either. The resistance, for unit length of the cylinders, is, in fact, calculated out by the rather complex formula:—

$$R = \frac{1}{\pi \mu} \log. \text{nat. } h;$$

Where

$$h = \frac{2a}{b + 2a - \sqrt{b^2 + 4ab}};$$

the symbol *a* standing for the radius of the cylinder; *b* for the shortest distance separating them; *μ* for the permeability, or in the electric case the specific conductivity of the medium.

Now, I happened to notice, as a matter that greatly simplifies the calculation, that if we confine our attention to a transverse

\* Cantor Lecture. Delivered before the Society of Arts, January 27th, 1890.

layer of the medium of given thickness, the resistance between the two bits of the cylinders in that layer depends on the ratio of the shortest distance separating them to their periphery, and is independent of the absolute size of the system. If you have the two cylinders an inch round, and an inch between them, then the resistance of the slab of medium (of given thickness) in which they lie will be the same as if they were a foot round and a foot apart. Now that simplifies matters very much, and thanks to my friend and former chief assistant, Dr. R. Mullineux Walmsley, who devoted himself to this troublesome calculation, I am able to give you, in tabular form, the magnetic resistances within the limits of proportion that are likely to occur.

The numbers from columns 1 and 2 of the following table are

TABLE VIII.—MAGNETIC RELUCTANCE OF AIR BETWEEN TWO PARALLEL CYLINDRICAL LIMBS OF IRON.

$\frac{b}{p}$ Ratio of least distance apart to peri- meter.	Magnetic reluctance in C.G.S. units = the magneto-motive force ÷ total magnetic flux.		Magnetic reluctance in inch units = the ampere-turns ÷ the total magnetic flux. Slab = 1 inch thick.	
	Reluctance.	Permeance.	Reluctance.	Permeance.

8.0	1.2624	0.792	0.3955	2.528
10.0	1.3250	0.755	0.4151	2.409

NOTE.—In the above table, unit length of cylinders is assumed (1 centimetre in columns 2 and 3; 1 inch in columns 4 and 5); the flow of magnetic lines being reckoned as in a slab of infinite extent, and of unit thickness. Symbols:  $p$  = perimeter of cylinder;  $b$  = shortest distance between cylinders. In columns 2 and 3 the unit reluctance is that of a centimetre cube of air. In columns 4 and 5 the unit reluctance is so chosen (as in the rest of these lectures wherever such measures are used), that the reduction of ampère turns to the magneto-motive force by multiplying by  $4\pi \div 10$  is avoided. This will make the reluctance of the inch cube of air equal to  $10 \div 4\pi \div 2.54 = 0.3132$ ; and its permeance as  $3.1931$ .

plotted out graphically in Fig. 46 for more convenient reference. As an example of the use of the table we will take the following:—

EXAMPLE.—Find the magnetic reluctance and permeance between two parallel iron cores of 1 inch diameter and 9 inches long, the least distance between them being  $2\frac{3}{8}$  inches. Here  $b = 2.375$ ;  $p = 3.1416$   $b \div p = 0.756$ . Reference to the table shows (by interpolation) that the reluctance and permeance for unit thickness of slab are respectively 0.183 and 5.336. For 9 inches thickness they will therefore be 0.021 and 48.02 respectively.

When the permeance across between the two limbs is thus approximately calculable, the waste flux across the space is estimated by multiplying the permeance so found by the average value of the difference of magnetic potential between the two limbs. And this, if the yoke which unites the limbs at their lower end is of good solid iron, and if the parallel cores offer little magnetic reluctance as compared with the reluctance of the useful paths, or of that of the stray field, may be simply taken as half the ampère-turns (or, if centimetre measures are used, multiply by 1.2566).

The method here employed in estimating the reluctance of the waste field is of course only an approximation; for it assumes that the leakage takes place only in the planes of the slabs considered. As a matter of fact, there is always some leakage out of the planes of the slabs. The real reluctance is always therefore somewhat less, and the real permeance somewhat greater, than that calculated from Table VIII.

For the electro-magnets used in ordinary telegraph instruments the ratio of  $b$  to  $p$  is not usually very different from unity, so that for them the permeance across from limb to limb per inch length of core is not very far from 5.0, or nearly twice the permeance of an inch cube of air.

We are now in a position to see the reason for a curious statement of Count du Moncel which for long puzzled me. He states that he found, using distance apart of one millimetre, that the attraction of a two-pole electro-magnet for its armature was less when the armature was presented laterally than when it was placed in front of the pole-ends, in the ratio of 19 to 31. He does not specify in the passage referred to what was the shape of either the armature or the cores. If we assume that he was referring to an electro-magnet with cores of the usual sort—round iron with

flat ends, presumably like fig. 11—then it is evident that the air gaps, when the armature is presented sideways to the magnet, are really greater than when the armature is presented in the usual way, owing to the cylindrical curvature of the core. So, if at equal measured distance the reluctance in the circuit is greater, the magnetic flux will be less and the pull less.

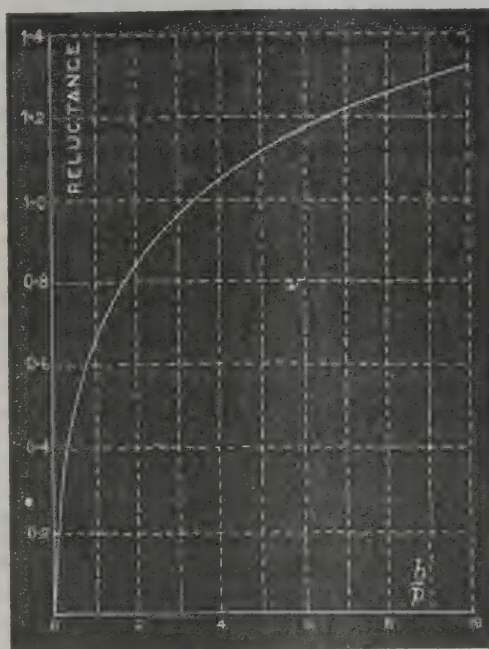

FIG. 46.—DIAGRAM OF LEAKAGE RELUCTANCES.

It ought also now to be evident why an armature made of iron of a flat rectangular section, though when in contact it sticks on tighter edgeways, is at a distance attracted more powerfully if presented flatways. The gaps, when it is presented flatways (at an equal least distance apart) offer a lesser magnetic reluctance.

Another obscure point also becomes explainable, namely, the observations by Lenz, Barlow, and others, that the greatest amount of magnetism which could be imparted to long iron bars by a given circulation of electric current was (nearly) proportional, not to the cross-sectional area of the iron, but to its surface; The explanation is this. Their magnetic circuit was a bad one, consisting of a straight rod of iron and of a return path through air. Their magnetising force was being in reality expended not so much on driving magnetic lines through iron (which is readily permeable) but on driving the magnetic lines through air (which is, as we know, much less permeable), and the reluctance of the return paths through the air is—when the distance from one to the other of the exposed end parts of the bar is great compared with its periphery—very nearly proportional to that periphery, that is to say, to the exposed surface.

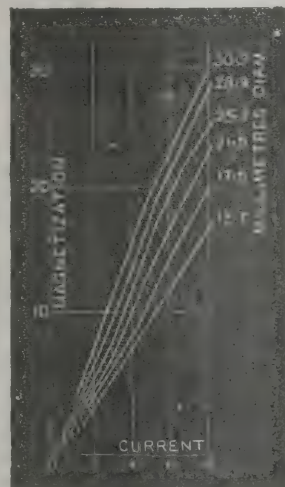

FIG. 47.—VON FEILITZSCH'S CURVES OF MAGNETISATION OF RODS OF VARIOUS DIAMETERS.

Another opinion on the same topic was that of Professor Müller, who laid down the law that for iron bars of equal length, and excited by same magnetising power, the amount of magnetism was proportional to the square root of the periphery. A vast amount of industrious scientific effort has been expended by Dub, Hankel, Von Feilitzsch, and others on the attempt to verify this "law." Not one of these experimenters seems to have had the faintest suspicion that the real thing which determined the amount of magnetic flow was not the iron but the reluctance of the return path through air. Von Feilitzsch plotted out the accompanying curves (Fig. 47), from which he drew the

inference that the law of the square root of the periphery was established. The very straitness of these curves shows that in no case had the iron become so much magnetised as to show the bend that indicates approaching saturation. Air, not iron, was offering the main part of the resistance to magnetisation in the whole of these experiments. I draw from the very same curves the conclusion that the magnetisation is not proportional to the square root of the periphery, but is more nearly proportional to the periphery itself; indeed, the angles at which the different curves belonging to the different peripheries rise show that the amount of magnetism is very nearly as the surface. Observe here we are not dealing with a closed magnetic circuit where section comes into account; we are dealing with a bar in which the magnetism can only get from one end to the other by leaking all round into the air. If, therefore, the reluctance of the air path from one end of the bar to the other is proportional to the surface, we should get some curves very like these; and that is exactly what happens. If you have a solid, of a certain given geometrical form, standing out in the middle of space, the conductance which the space around it (or rather the medium filling that space), offers to the magnetic lines flowing through it, is practically proportional to the surface. It is distinctly so for similar geometrical solids, when they are relatively small as compared with the distance between them. Electricians know that the resistance of the liquid between two small spheres, or two small discs of copper immersed in a large bath of sulphate of copper, is practically independent of the distance between them, provided they are not within ten diameters, or so, of one another. In the case of a long bar we may treat the distance between the protruding ends as sufficiently great to make an approximation to this law hold good. Von Feilitzsch's bars were, however, not so long that the average value of the length of path from one end surface to the other end surface, along the magnetic lines, was infinitely great as compared with the periphery. Hence the departure from exact proportionality to the surface. His bars were 9.1 centimetres long, and the peripheries of the six were respectively 94.9, 90.7, 79.2, 67.6, 54.9, and 42.9 millimetres.

It has long been a favourite idea with telegraph engineers that a long-legged electro-magnet in some way possessed a greater "projective" power than a short-legged one; that, in brief, a long-legged magnet could attract an armature at a greater distance from its poles than could a short-legged one made with iron cores of the same section. The reason is not far to seek. To project or drive the magnetic lines across a wide intervening air-gap requires a large magnetising force on account of the great reluctance and the great leakage in such cases. And the great magnetising force cannot be got with short cores, because there is not, with short cores, a sufficient length of iron to receive all the turns of wire that are in such a case essential. The long leg is wanted simply to carry the wire necessary to provide the requisite circulation of current.

We now see how, in designing electro-magnets, the length of the iron core is really determined; it must be long enough to

TABLE IX.—EFFECT OF JOINTS IN WROUGHT IRON BAR  
(NOT COMPRESSED).

H	B				Mean thickness of equivalent air-space for one cut.		Thickness of iron of equivalent reluctance per cut.

allow of the winding upon it of the wire which, without overheating, will carry the ampère turns of exciting current which will suffice to force the requisite number of magnetic lines (allowing for leakage) across the reluctances in the useful path. We shall come back to this matter after we have settled the mode of calculating the quantity of wire that is required.

Being now in a position to calculate the additional magnetising power required for forcing magnetic lines across an air gap, we are prepared to discuss a matter that has been so far neglected, namely, the effect on the reluctance of the magnetic circuit, of joints in the iron. Horse-shoe electro-magnets are not always made of one piece of iron bent round. They are often made, like fig. 11, of two straight cores shouldered and screwed, or rivetted into a yoke. It is a matter purely for experiment to determine how far a transverse plane of section across the iron obstructs the flow of magnetic lines. Armatures, when in contact with the cores, are never in perfect contact, otherwise they would cohere without the application of any magnetising force; they are only in imperfect contact, and the joint offers a considerable magnetic reluctance. This matter has been examined by Prof. J. J. Thomson and Mr. Newall, in the Cambridge Philosophical Society's Proceedings, in 1887; and recently more fully by Prof. Ewing, whose researches are published in the *Philosophical Magazine* for September, 1888. Ewing not only tried the effect of cutting and of facing up with true plane surfaces, but used

different magnetising forces, and also applied various external pressures to the joint. For our present purpose we need not enter into the questions of external pressures, but will summarise the results which Ewing found when his bar of wrought iron was cut across by section planes, first into two pieces, then into four, then into eight. The apparent permeability of the bar was reduced at every cut.

(To be continued.)

## NEW PATENTS—1890.

16264. "Improvements in electro-motors and dynamo-machines." H. CHITTY. Dated October 13.

16272. "Improvements in or appertaining to globe or shade holders for incandescent electric lamps, in part applicable to other lamps." R. L. B. RATHBONE. Dated October 13.

16279. "Improvements in the process and apparatus for electrical casting of metals." N. SLAWIANOFF. Dated October 13.

16322. "Improvements in insulating cells for electric batteries." S. C. C. CURRIE. Dated October 14. (Complete.)

16415. "Improvements in methods of and apparatus for utilizing electricity in the formation of sheet metal articles." M. W. DEWEY. Dated October 15. (Complete.)

16472. "A new or improved automatic coin freed apparatus for giving electric shocks." B. J. STACEY. Dated October 16.

16534. "New or improved electrical priming or electrical frictional priming screw plugs." A. LONGSDON. Dated October 17. (Complete.)

## ABSTRACTS

### OF PUBLISHED SPECIFICATIONS 1889.

13960. "Improvements in and relating to apparatus for measuring electric currents and for weighing bodies or substances." A. L. SHEPARD. Dated September 4. 8d. The operation of the apparatus is as follows:—The speed of an electro-motor is so regulated that at any moment the pull of a centrifugal governor equal to the pull of the current being measured. Any increase of the said current will cause a coil upon the extremity of a beam or balance lever to approach the coil or magnet in the said circuit, and thus lower or depress the extremity of the said beam or balance lever carrying the said coil, and consequently raise or elevate the other extremity thereof, and complete the circuit to the electromotor. The speed of the latter will then be increased so that the arms carrying the balls of the governor will fly outwards by centrifugal force, and act upon the other extremity of the said beam or balance lever, so as to draw down or depress the same, and cause the said beam or balance lever to resume its normal position of equilibrium. 6 claims.

14113. "Improvements in switches for electrical propulsion purposes." M. IMMISCH. Dated September 7. 11d. Consists in the employment of a make and break lever, which is so combined with the switches that they can only be shifted after the make and break lever has been first moved so as to break the circuit. 6 claims.

14114. "Improved switch for electrical tramcars." M. IMMISCH. Dated September 7. 11d. The switch ensures the locking of the parts for effecting the necessary changes in any position to which they have been shifted, that is to say, on one side or other of a central position, or in the central position, when the circuit is broken. 2 claims.

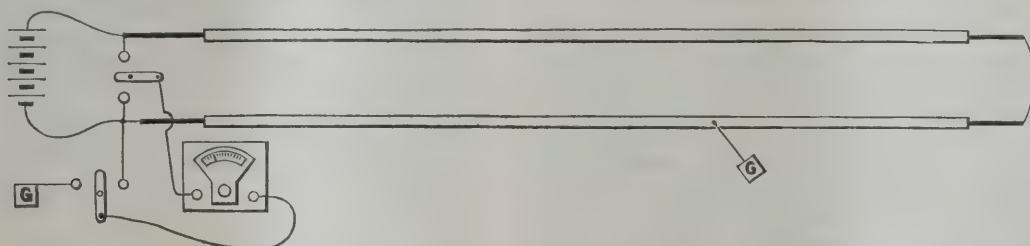

14447. "Improvements in or appertaining to electric or cable-propelled rail or tramway cars, and to brake mechanism therefor, partly applicable to other vehicles." W. P. THOMPSON. (A communication from abroad by S. A. Bemis and L. Pfingst, of America.) Dated September 13. 8d. Particularly relates to improved means for mounting and spring-supporting the car body on the trucks, to improvements in means for hanging the motor when used in connection with the truck, from what is termed the yoke frame, whereby it may be advantageously supported for its most efficient operation; it further relates to an improved construction of the yoke frame for the proper supporting of the brake mechanism, whereby said mechanism is independent of the car body, and will not be affected by the bounding motion thereof; it further relates to brake devices for the trucks of cars of the above-named description having such a construction and arrangement that the space between the car wheel axles of the truck which is required for the electric motor or motors, or for a grip mechanism in case the truck is used for a cable car, is not encumbered inconveniently with any of the brake-operating mechanism; the invention further relates to an improved shoe and connection for the bracing or trussing parts between the truck and the sill of the car. 9 claims.

15230. "Improvements in electric batteries." Sir WILLIAM VAVASOUR. Dated September 27. 1s. 8d. The inventor provides a porous pot, or a partially porous cell, containing or surrounding one of the electrodes of the battery; this porous pot, or partially porous cell, is closed or cemented up with the electrode therein, but

having a connection with the electrode passing through, and provided with inlet or outlet passage or passages for the liquid under pressure. The other electrode or electrodes is or are placed outside the porous pot or partially porous cell. The exciting or opposing liquid is forced by pressure through the porous pot, and the invention being applicable to single or double fluid batteries. 4 claims.

15402. "Improvements in or relating to alternate current electric distribution." W. P. THOMPSON. (A communication from abroad by G. Westinghouse, jun., of Pittsburg. Dated October 1. 8d. Claims:—1. The combination with a circuit supplied by alternating electric currents, of two or more electric converters having their primary coils connected in series in said circuit, and an incandescent electric lamp or other translating device connected in the secondary circuit of each converter, the coils of the converter being so proportioned to the mass of iron in the corresponding cores that, upon the interruption of the circuit through any lamp, a normal current is allowed to pass through the other converters by reason of the high magnetic saturation of the core of the corresponding converter. 2. In a series system of secondary distribution, a converter so proportioned that the self-induction of its primary with open secondary is the equivalent of the resistance of the translating devices normally on the secondary circuit. 3. In a series system of electrical secondary distribution, converters having their primary coils so proportioned that the inductive opposition to the current is approximately the same when the secondary is open as when the secondary is closed through its normal circuit.

15449. "Improvements in electrical cables." W. T. GLOVER. Dated October 1. 6d. The inventor uses either a solid wire or strip or a strand of fine wires or strips as a conductor, and this conductor he insulates, and around this insulation he places an equivalent to the core in the shape of fine wires or strips, and he insulates these if desired. He then lays the requisite number of conductors so prepared into the cable, encasing the cable in insulating and protecting material if desired. 1 claim.

15769. "Apparatus for measuring and recording electric currents." Sir W. THOMSON. Dated October 8. 11d. Claims:—1. The instrument for measuring and recording electric currents, substantially as described and shown on the drawings. 2. In an instrument for measuring and recording electric currents by different positions of an indicator, the use of two bars attached to the indicator at right angles to one another, carrying adjustable weights for varying and adjusting the sensibility and zero of the instrument. 3. In an instrument for measuring and recording electric currents, the combination of an indicator and recorder with a cam caused to turn at a uniform speed; the recorder coming in contact with the cam once in each revolution, and remaining in contact for a longer or shorter time according to the strength of current, and recording the amount of current while in contact with the cam either by a trace on a revolving drum or by a train of counting wheel work, or by both simultaneously, substantially as described. 4. In an instrument for measuring and recording electric currents, the use of a pendulum or spring for controlling the motions of the indicator by touching it through part of its range.

15968. "Improvements in insulating supports for underground electrical conductors." W. C. JOHNSON and S. E. PHILLIPS. Dated October 10. 6d. Claims:—1. Supporting electrical conductors in underground troughs or channels by means of insulating supports having receptacles containing an insulating liquid so arranged as to effect perfect insulation between that part of the support to which the conductor is attached, and that part which is connected to the trough or channel, substantially as described. 2. The use for supporting electrical conductors in underground troughs or channels of insulating supports, constructing substantially as herein described with reference to the drawings, wherein a receptacle or cup-shaped insulator, containing an insulating liquid, is so combined with the supports for the conductors as to effectually insulate the support of the conductor from the part of the insulator connected to the trough or channel.

16599. "Improvements in and relating to electric date and time stamps." C. ADAMS-RANDALL. Dated October 21. 1s. 1d. Has for its main object the combination of number-printing apparatus with electric date and time printing apparatus. 5 claims.

16697. "Improvements in electro-dynamic machines." O. T. BLATHY. Dated October 22. 11d. Claims:—1. An electro-dynamic machine, consisting of a combined alternately acting transformer and motor, having two alternate current magnetic fields (or groups of these) separate from and independent of one another, the phases of which are displaced from one another, and

of a revolving armature with coils closed upon themselves, acted upon by the two magnetic fields or groups of fields, at different parts of its surface and revolution, substantially as set forth. 2. An electro-dynamic machine, such as is referred to in claim 1, having two field magnets, or groups of these, placed at an angle to one another, and an armature with its coils straight, substantially as set forth. 3. An electro-dynamic machine, such as is referred to in claim 1, having two parallel fields, or groups of these, and an armature with its coils made in two parts, the one part at an angle to the other, substantially as set forth.

## CORRESPONDENCE.

### Telephone Switchboards.

In reply to your correspondent "Z." in last week's REVIEW, we should be glad to show him one of the switchboards in question in operation, and give full information at our London office, 11, Queen Victoria Street.

Telegraph Mfg. Co. Ltd.

November 5th, 1890.

### A Speedy Method of Localising Defects in an Electric Lighting Cable.

Referring to the above article which appeared in your issue of October 10th, I submit the following, as it may contain some merit, there being less apparatus necessary.

Attach the battery to the two free ends of the cable the farther ends being connected as were shown.

With a sensitive voltmeter grounded, take the P.D. of X, calling it V, then take a reading of the remaining section, calling it V', the equation will be

$$X : 900 - X :: V : V'$$

or

$$X = \frac{(900) V}{V + V'}$$

A simpler method would be to take the total P.D., calling it V, then the P.D. of X calling it V', this formula will then be

$$X = \frac{V' (900)}{V}$$

The above occurred to me while perusing the article, and while original with me at the moment, doubtless have been used by others with various modifications. Still hoping that they may be of use to some, I remain

Osborn P. Loomis.

Brooklyn, N.Y., U.S.A., October 22nd, 1890.

### Rule for Electric Bell and Alarm Wiring.

In the fitting of electric bells, signals, fire and burglar alarms, &c., and more especially in repairs, renewals, or additions, it is of great importance to be able to distinguish "battery wires"—i.e., wires leading direct from or to the battery—from "connecting wires," i.e., wires running between pushes and indicators, indicators and bells, alarms and bells, &c.

I have devised a rule (see p. 56 "Practical Electrical Notes," 2nd Ed.: Spon), the adoption of which enables "connecting wires" to be distinguished at a glance from "battery wires," and, what is more, "+" battery wires" and "− battery wires" are clearly indicated.

*My rule is as follows:—*

"All wires leading from the + pole of the battery to any push, &c., should be of a plain bright colour (say white, yellow, or red); all wires running between apparatus—connecting wires—should have a covering in which two or more colours are blended; and all wires leading direct back to the battery should be of a plain dark colour, preferably black."

The adoption of this rule by electric bell fitters would, I beg to suggest, save much valuable time which is now wasted in what is generally termed "testing."

W. Perren Maycock, A.M. Inst. E.E.

November 3rd, 1890.

### The Elmore Copper Process.

Owing to my absence abroad, I have been unable to answer earlier the questions put by you in your leader of the 17th inst.

I wish, however, now, without troubling you or your readers with any fuller details of the Elmore process than I have given in your own and other publications, to draw attention to the following errors in your articles of the 17th and 24th inst.

1. Your calculation of the current necessary to deposit 20 tons of copper per week is practically ridiculous.

2. The resistance of "the bath," founded upon this purely imaginary current is equally ridiculous.

3. Your deduction as to the necessary size of tanks involves a like absurdity.

4. The figure of current density quoted by you from Mr. J. T. Sprague is more than double of what is possible in ordinary commercial depositing, with anything like good results.

This point is fully entered into in M. Fontaine's book from which you have quoted. The current density, therefore, which is feasible with the Elmore process being about three times that possible in ordinary work, presents an advantage of no small importance.

5. The assumption by you that the price of a horsepower is about £10 per annum—the week being 60 hours—is entirely inapplicable to the case considered by you, because—

(a) A week in an electro-depositing factory averages about 156 hours in place of 60 hours.

(b) A factory of such a kind is not set up (as suggested by you) in a city where floor space is expensive.

(c). In a city coal is not to be obtained delivered free at 8s. 6d. per ton as it is at present in the Elmore factory near Leeds.

(d.) In the case of an industry in which power forms a large proportion of the working expenses, every attention is paid to reducing the cost of the power by the use of suitable engines and power-saving apparatus.

I am only surprised that you should have dared to estimate the cost of electrical deposition on an assumption so opposed to the experience of engineers.

6. Even if the cost of power were such as you have assumed it to be, the quality of the articles produced and the small amount of labour required would still leave a very large profit to the company for depositing copper articles only, and it should be remembered that copper is only one of the metals to which the process can be applied.

I would ask you how can you reconcile the figures of cost given by you in a table on page 479, where the average cost of producing a ton of refined copper is given at about £12 with the fact that electrolytically refined copper can be bought in the open market at a price which would thus entail upon the manufacturer a dead loss of over 30 per cent.?

The value of the various figures given by you may be fairly gauged by this sample.

If any doubt exists in the minds of yourselves or

your readers on this point, a moment's enquiry of any installer of electrolytic plant will confirm the truth of my remarks.

7. You assume that the value of the Elmore wire process can only be due to the probability of it commanding a higher price.

This is entirely incorrect, and I believe that the company can show a very handsome profit in this department, even at the same price as wire of not more than 98 per cent. conductivity, which is the usual quality guaranteed and not 96 per cent. as quoted by you.

8. In opposition to your calculations we may safely put the reports of the various eminent men who have examined and tested the process, and, in addition to these (which have been published), I may add that the English calculations and results have been quite recently checked and verified with great care by competent French engineers who have visited the works at Leeds, and, after making their tests, have given a certificate as to the correctness of the cost of manufacture and the quality of the articles which you on your own responsibility, and without having seen the process, have thought well to deride.

I have selected the above eight points with a wish to make my letter as short as possible, and in justice to the Elmore Company, I trust that if I am incorrect in any of my statements, you will publicly make the same known, but if not it will only be left for your readers to conclude that you have made an unwarrantable attack upon a new industry, without such knowledge of the matter as alone could justify you in doing so.

I make no comment upon your high principled suggestion as to how persons might successfully steal the ideas of the inventors. So far as the Elmore patents are concerned, I have no doubt that the company will be perfectly ready to meet any such attempts, and to put the infringer through what you seem desirous that the patents should undergo, viz., the fire of the Court.

W. Stepney Rawson.

October 29th, 1890.

### The Lane-Fox Patents.

I willingly accept the challenge to me in your last article on my patents.

Stated briefly, and stripped of all garnishments, the following are the chief arguments which you invite me to overthrow:

1. My inventions are dependent upon the working of Ohm's law. I am not the discoverer of this law; *ergo*, there is nothing new in my inventions.

2. An arrangement of parts forming a novel combination does not constitute a patentable invention, "the parts themselves being the patentable matter, and not their rearrangement."

3. The use of secondary batteries as *reservoirs* of electrical energy does not imply or include their intermittent use (as a *reserve*), but only their constant use as a "simultaneous" accompaniment to the primary source of energy.

4. Although primary batteries are unsuitable for the maintenance of a constant potential (and therefore for electric lighting); yet inasmuch as the same general law governs the electric currents generated by all sources of dynamic electricity, a vague proposal for the utilisation of primary batteries for electric lighting constitutes an anticipation of my system in which they are *not* used.

I believe the mere statement of these weighty propositions, in all their naked simplicity, will carry (to most minds) their own refutation. I leave it to you to correct me if the above statement does not fairly represent your main arguments.

In order, however, to comply more literally with your request for a further *explanation*, I now offer a few more remarks on each point *seriatim*.

1. This affects the novelty of my system of distribution. Now I maintain that there is an important dif-

ference—a difference in *kind*, not merely in *degree* or in *detail*—between my system and the arrangements and projects which you and others have compared with it. The object I had in view was essentially different to that of previous electricians working in the same field. Their objects fall under two headings, namely :

(a) The more effective utilisation of the current in a circuit, from whatever source, treated as a fixed quantity by “dividing” or “subdividing” it.

(b) Obtaining the “maximum effect” from the generating source, as in the case of batteries, by arranging the cells for “quantity” or for “tension” as required.

My main object was to obtain *constancy of the available potential at any point irrespective of the total quantity of current flowing*.

You mentioned Werdermann as a possible anticipator of my system of distribution, but a reference to his patent No. 2,477 of 1878 shows clearly that neither did he contemplate the combination of high resistance incandescence lamps constructed of a continuous “luminous bridge,” with the use of secondary batteries as reservoirs, nor had he grasped the root idea of a constant potential *with a varying load*. Indeed, according to his project—for I am not aware that it was ever tried on a practical scale—a constant potential could only be maintained by keeping up, day and night, the full current required to work the total number of lamps in the installation.\*

2. You have here propounded quite a novel doctrine. Fortunately for the owners of a large number (if not the majority) of the most valuable patents, it has not yet been adopted by the Chancery Division, or any other Court that I know of which has jurisdiction in patent cases. But I content myself with referring you on this point to any text-book of English patent law.

3. I have never admitted that the dynamos, accumulators and lamps must *necessarily act simultaneously* in order to work under my system. On the contrary, I expressly state in my leading specification above referred to, that the charging and discharging of the cells may be effected at different times to suit the exigencies of an irregular and intermittent demand (see page 4 of the amended specification No. 3,988\*\* of 1878). I should have thought, however, that even if I had omitted to say so, common sense would suffice to decide that the chief object of a reservoir is just the advantage of employing it when the primary source of supply fails, or is cut off.

4. My answers to the last three objections really cover this also. You say, indeed, that “it is only a question of proportioning batteries to their work,” while you have already admitted that in the case of primary batteries this cannot practically be done. That is to say, no primary batteries at present known can be rendered suitable for maintaining a constant potential difference for electric lighting purposes.

With regard to the main question at present raised, namely, the novelty of my system, while I have been unable to find anything approaching an anticipation, I have been fairly astounded at the universal ignorance both of the system itself and of the principles upon which it is based, which continued to prevail up to the date of its first adoption in practice in 1882. Thus, out of a long article which appeared in the *Fortnightly Review* of February, 1879, reviewing the progress of electric lighting down to that date, Prof. Tyndall devotes about a page and a-half to the distribution of

incandescent electric light according to Edison’s “alleged mode,” but his remarks show clearly that he had no inkling at the time of any system of general supply *with a variable load at a constant potential*; yet this was two months after my own description of my system had been published occupying over a column of the *Times*. He spoke throughout of the “well-known” law by which the current from a certain source may be divided and sub-divided, and compared such a “system” in the first instance, to a river dividing itself round an island or a number of islands, and reuniting itself in “the trunk stream;” while, in the second instance, he makes a somewhat elaborate comparison with the circulation of the blood. (The italics are mine.) Evidently, however, the learned professor had little confidence in the feasibility of this “alleged mode,” for, with prescient sagacity, he concludes this part of his article as follows: “Knowing something of the intricacy of the practical problem, I should certainly prefer seeing it in Mr. Edison’s hands to having it in mine.”

I should be presuming too much upon your patience and courtesy were I to attempt to quote in this letter all the instances which I could adduce, between that date and 1882, of the same all-prevailing ignorance of my invention, (or let me at least say of the system of distribution, &c., I claim as my invention, and which has since that year been the most extensively adopted).

Suffice it to add that, even as late as 1881, at the Society of Telegraph Engineers, elaborate systems were propounded of maintaining constancy of light by a similar device to Werdermann’s, above referred to, that is to say, by substituting equivalent *resistances* for any lamp when not in action.

Having now dealt, I think, pretty exhaustively with the various objections which you have at present made against my claim, let me add a few words from a more personal standpoint. I much regret that anything like animosity should have crept into this controversy, yet I cannot explain the attitude which the trade generally (with a few honourable exceptions) have taken up towards me and my work on any other grounds. I can understand a certain reluctance to pay me or my syndicate royalties which had not been claimed while my patents remained in other hands; it is only human nature to examine such claims very closely before “shelling out.” What I do not understand is that I should be abused and ridiculed for *making* them, as if I were bound, indeed, by the previous inaction of those to whom I had assigned my rights. Surely the patentee of a system has a good right to consider himself entitled to some substantial return from it after it has been employed by nearly the whole electric lighting world? If not, a better reason should at least be given for vilifying him and spurning his claims, than any which has yet been made public.

But what I have been most pained and perplexed at in this connection is that some of those who are now most active in attacking me were actually first introduced into the electric lighting industry through me, having received their early training at my hands. *Et tu, Brute!* I might well exclaim to more than one of these; but, happily, my position is not quite so desperate as poor Caesar’s. It is some of these very individuals who are now trying to get the public to believe that I did little or nothing for the practical development of the system which I am now claiming as my own.

Fortunately, I do not depend on my later patents only for evidence to the contrary. The true history of the whole subject, and the share I had in it, remains yet to be written. One fact only in this connection I may, perhaps, be allowed now to record, and one which will no doubt take most of your readers by surprise. It is this, that the modern “E.P.S.” accumulator was the outcome of my introducing Messrs. Volekmar and Philippart, jun., into this country, and the first commercially-successful storage batteries ever made over here were made with my

\* The late Sir Francis (then Colonel) Bolton, in his first *resumé* of electric lighting patents, read before the Society of Telegraph Engineers, on May 14th, 1879—that is, probably somewhat before the official publication of my leading specification—summarised Werdermann’s patent after referring to his semi-incandescent lamp as follows:—“When a number of lights are joined up in parallel arc, a switch to each is provided, such that when one light is intentionally extinguished, a resistance equal to that of the light is inserted in its place, and the light in the rest of the lamps is unaltered.” This, although incomplete, is a better summary than that which he gave three years and a-half later of my specification No. 3,988, out of which he only selects the *lamps* for notice.

active co-operation at the Brush Company's Portpool Lane works, of which I was the founder and manager.

Regretting that I am obliged to blow my own trumpet to this extent, I am, &c.,

St. G. Lane-Fox

October 4th, 1890.

At a meeting of the Defence Association, formed to resist the claims being made by the Lane-Fox Electrical Company in respect of the Lane-Fox patents, held at the offices of the Kensington and Knightsbridge Electric Lighting Company, Limited, at 148, Brompton Road, the following resolution was passed:—

"That the list of members of this association be closed on Saturday fortnight, November 22nd, and after that date, members of the electrical trade, who, being attacked by the Lane-Fox Electrical Company, are desirous of availing themselves of the benefits of this association, will be required to pay the double fee of £50." Under these circumstances, any members of the trade who wish to join the association, should communicate with me before the above-mentioned date. I may mention for the benefit of those who are not fully acquainted with the steps that have been taken in the matter, that several opinions have been obtained and submitted to counsel by different members of the association, all of which agree in advising that the claims of the Lane-Fox Electrical Company cannot be sustained. Trusting you will be able to insert this in your next issue, as it is most important that it should reach all your readers,

FOR THE DEFENCE ASSOCIATION,

R. S. Erskine, *Hon. Sec.*

November 4th, 1890.

#### The Electro-Deposition of Copper.

Your calculation of the current requisite to deposit 20 tons of copper in 60 hours is (of course) correct. But, for this work, even in this country, the week may be taken as 144 hours at least; so that the current to deposit 20 tons of copper per week would thus be reduced from 287,600 to 118,800 ampères.

I may observe, with all due diffidence, that this large figure of production—over 1,000 tons of manufactured copper per annum—appears to be in excess of any probable demand at the present time, and must therefore be considered as prospective, if not as speculative or gratuitous. Why, M. Roux, at Marseille, has been contenting himself with an output of 89½ tons per annum; whilst the great Norddentoche Affinerie produces but ten times that weight. And these firms only refine; they do not manufacture.

In regard to the current density allowable, this depends almost entirely on the degree of purity of the anodes, upon which are dependent the character of the electrolyte and the extent of the back electromotive force. With the anodes ordinarily used in refining copper, it is not generally safe to go beyond or, indeed, so high as a density of 10 ampères per square foot of anode (or cathode) surface. At the various refineries the density actually varies from about one-fifth to twice this value. In the Elmore electro-deposition process, the anodes would probably be of comparatively very pure copper; and the cathodes, though not plane surfaces, would, from the nature of the process, be in great measure protected against the detrimental effects ordinarily resulting from high current density. A density of over 20 ampères per square foot would no doubt in this case be practicable.

Perhaps the most important consideration in relation to the above-mentioned process, is that of the comparative size of the deposition tanks, dependent upon the resistance between the anode and cathode surfaces. It

appears inevitable that this will be very considerably greater than that which obtains in the electrolytic refining of copper. In the latter process the distance between the anode and cathode surfaces, both in the form of plates, varies from about ½ inch to 4 inches; the most usual distance being about 2 inches. The resistance per square foot of anode varies from 0.0108 to 0.0322 ohm. Without being practically acquainted with the details of the Elmore process, I think I may, nevertheless, safely say that the tank resistance per square foot of anode will, in this case, be much greater, that the consecutive anode surfaces will be much farther apart; that the cathode surface, no longer in the form of a plate, will be disproportionately small (or, in other words, the anode surface will or should be disproportionately large with a view to reduce resistance as much as possible); and that the tanks, for a given output, will be much larger than those in use for the electrolytic refining of copper.

On the other hand, and in conclusion, I may point out that the deposition would probably be effected under an E.M.F. considerably less than one volt. In electrolytic refining, the E.M.F. for each tank in a series varies from 2 to 5 volt; the mean value being 3 volt. In a process where the anodes would be of comparatively pure copper, the E.M.F. should be below this mean value—unless, indeed, such untoward conditions are realised that economy of horse-power becomes impracticable in view of the urgency of reducing expenditure of capital on plant.

Desmond G. FitzGerald.

#### Accumulator Explosions.

It has often occurred to me that the above subject has not received the attention in your columns which it probably deserves. But I have attributed the omission to the exercise of a wise discretion, seeing that the public are so prone to take alarm at every bogey which presents itself, and that in certain quarters a considerable amount of prejudice exists.

Since, however, attention has been called to the subject in a somewhat objectionable manner, perhaps the sooner the public are made acquainted with the real facts, and to what extent danger, if any, really exists, the better.

I may say that for a period extending over five or six years, during which the Great Northern Railway Company have had in use, under my charge, some hundreds of accumulators for both train and stationary lighting, only four cases of explosion have come under my notice, and these were only of a very insignificant character, the damage in each case being confined to the particular cell in question. Three were occasioned by the connecting straps becoming oxidised and breaking off inside the cell just above the surface of the liquid, through the motion of the trains and arcing across, which, of course, ignited the gases. It is needless to state that these were teak lead-lined cells, fitted with lids and vent holes.

The remedy for this seems comparatively simple. Have the connecting lugs or straps made of sufficient strength to resist all possible vibrations, and see that they are properly *burnt*, not tin soldered on. Also, where possible, duplicate them; finally, the connections from cell to cell should be made by a separate flexible connector, and not simply by means of a bolt through the two adjoining straps.

The fourth case was occasioned by the carelessness of a workman holding a lighted match over the cell while charging; which, however, was against orders, as the usual practice is to use a small glow lamp, with the globe whitened or silvered on one side so as to reflect the light into the cell.

In conclusion, if proper care were exercised in the manufacture, setting up and management of accumulators, explosions would be almost impossible.

F. W. Cooke.

## ELECTRIC RAILWAY ENGINEERING.

CONSIDERING the rapidity with which electric railways were constructed, and the almost entire absence of precedent and experience, it is not to be wondered at that breakdowns on American lines have been frequent and repair bills in many cases rather heavy. During the great "boom" it was necessary to get through the work quickly, in order to satisfy the enormous demand upon two or three companies then in existence, none of which had much practical experience in railway work. New men had to be trained in the space of a few weeks, and sometimes only days, to take charge of the entire plant and equipment of a tram line, taxing to the utmost the mental and physical resources of both the trained and the trainers.

It speaks well of the indomitable energy and perseverance of Americans that they have been able, under most trying circumstances, to keep up a good reputation for electric traction—in fact, to lay the foundation for a gigantic new industry. It was not to be wondered at that motors, gearing, switches, lines, and insulation broke down with frequency, but the surprising part was that the men in charge did not break down themselves. Many a man possessed of self-esteem, and sufficient regard for the reputation of his employers, could tell of anxious days and wearisome nights devoted to hasty repairs, discovery of defects, and schemes for remedies. These men had a complex set of duties and cares. Besides keeping things going with the outward appearance as if nothing had happened, whilst hourly accidents did occur, they endeavoured to show that electric traction is not only better, but also cheaper than any other kind of traction. The eyes of the sceptical public were ever upon them; their work was eminently a public one, and well they did it so far. One by one improvements were suggested and acted upon, and we can see by recent publications that they are not now afraid to discuss publicly certain defects, with a view of getting sug-

gestions for remedies. Rules and specifications are being framed for purposes of future work, with the express purpose of avoiding all the past errors and thus to insure permanent success.

The "General Instructions for Overhead Line Construction for Electric Railways," issued by the Westinghouse Electric Manufacturing Company are a timely and sensible innovation, which deserve imitation in other branches of this industry. We shall reprint these, feeling certain that they will interest those readers who follow up the progress of electric traction. The methods of connecting ground wires, the best kinds of poles and how to plant them, together with overhead wires and fixtures are fully described. No doubt there are differences of opinion as to the best methods of doing these things, but if these rules are followed, little difficulty should be experienced in maintaining the line in good working condition. Perhaps at some future date other firms with large experience will frame rules or instructions for the proper construction and maintenance of other equally, if not more important, parts of electric railways, especially with details appertaining to the cars themselves.

## THE TAIL OF A LAME FOX.

(*Very much after Æsop.*)

A MODERN fabulist, who, until now, has evidently mistaken his vocation in life, has sent us the following:—

Once upon a time, an old Farmer named Moses Gee was walking in his poultry-yard, when he overheard an animated discussion between a goose, a Swan, and a Fox, as to the ownership of some eggs. The goose said they were hers, because they were golden; the Swan said they were hers because they glowed so brightly; and the Fox said they were his because they were laid on the ground, and as he owned the "earth" they must be his. But the birds replied, "We live on the water, in the old dam, and the neighbouring streams,

and, though you may claim the earth, that has nothing to do with us." "Oh!" said the Fox, triumphantly, "my family has burrowed for years in the ground, and currents of water now run through these tunnels into the reservoir that I first thought of." "But did you make the reservoir? And what about the old pump that feeds the reservoir—is that yours also?" "Well—yes—nearly," said the Fox, "For, as I claim the earth, surely the streams, and the dam, and the pump must be mine." The birds were silent; but a small, newly-fledged Drake came forward, and said he believed the Fox was right, for he knew much about reservoirs. He had been nearly choked in one, there was so much mud and weeds, and he would have been drowned had not a kindly frost come and frozen the water. This pleased the Fox, and he whispered something to the Drake about giving him part of the earth, when he got it. The Farmer, who heard all this, now noticed for the first time that the Fox was lame and had lost his Brush. The Fox, observing this, seemed embarrassed, and said, "I know I am a poor lame-Fox, and have lost my Brush, but in this you ought to pity me." The Farmer replied, "I would have pitied you, but for the arrogant claims you made just now. But where did you lose your tail?" The Fox sighed, and said something about his Webb-footed friends, who had made a sell on him. Here he became pensive; then looked angrily at the goose and the Swan, and said he had nearly learned to lay eggs himself once, light ones that would float in the currents from the reservoir. "Oh!" said the birds, "The idea of a fox laying eggs. Why, we could not lay such nice ones but for our vegetable diet of bamboo and cotton seed, and a Fox cannot eat that." At the mention of eating, the Fox looked hungrily at the little Drake, who ran away, saying he did not want to be eaten, and the Fox might keep his "earth" to himself. There was then a great commotion in the farmyard, and Moses Gee, the farmer, said, "Birds, go on and lay your eggs. The Fox is lame. He cannot hurt you: and as to his claim, all the farm, and stream, and reservoir, were mine before any of you were born, and you are all free to do as you please." At this the Fox ran away, and they all lived happily ever after.

---

## THE CENTRAL STATION AS AN INVESTMENT.

---

IT is evident that the electric lighting business has taken a firm hold as an industry of the world, and that the supply of current for motive purposes will be in increasing demand. Even in this country, the requirements of the public have outgrown the power of private firms to deal with, so that it has been imperative to form large corporations with immense capital to grapple with the task. Central stations have been erected and fitted in many parts of London, from whence the demand for the electric cur-

rent can be met. Districts have been assigned to the supply companies, and the town mapped out in a similar manner to what existed formerly with the various gas companies, before these latter were consolidated into two huge corporations. The question now arises, Will these stations pay? According to Mr. B. E. Sunny (who read a paper before the Chicago Electric Club meeting on October 20th last), that will depend on good engineering, as the whole secret of dividend-paying enterprises is in their ability to run reliably, every day and every year, without subjecting the machinery to excessive and abnormal demands, and in the avoidance of rebuilding, or abandoning original investments. The plant up to the point of normal and safe output should be fully employed, as well by day as by night; it is the duty of the management, therefore, to endeavour to utilise the machinery during the day in driving motors or charging accumulators, or in any other way that will bring grist to the mill; further the price at which the electric current can be produced, and that at which it can be sold, leave a margin of profit that ought to be satisfactory.

Now, commercially, the business may be considered a success, from the fact that it is ever increasing. How then does its record read from the investor's standpoint? Can it be reckoned on the same footing with gas-works, water-works, or railways as a dividend producer? Most decidedly it can, and perhaps no people recognise the future of electric lighting more than the gas companies themselves. The *American Gas Directory* states that the gas companies are operating 32,000 arc lights and 140,000 incandescents. In one year these companies have increased their ownership in electric lights nearly 50 per cent., thus showing their belief in the earning power and permanency of the electric light. Hitherto, the ratio of expansion of business has been put much too low; in consequence, stations have been built on far too small a scale, necessitating, after perhaps only a couple of years, an entire reconstruction of premises and plant to meet the ever-growing demand for electric lighting. Cheap and scratch plants will never pay a dividend in the long run. To be profitable, an installation should be furnished with standard types of engines, dynamos, and apparatus that are not likely to become old-fashioned for many years to come.

By not, at the outset, building a station on a plot of sufficient area, as patrons increase the plant has to be added to until the place is crammed in every corner with a perfect chaos of machinery, and presents what Mr. Sunny concisely calls an exhibition of engineering gymnastics. This kind of station is a financial success, working always at its maximum output, until the demand exceeds the supply, and it becomes necessary to rebuild. The rebuilding means, in many cases, selling off the old machinery at an enormous sacrifice, and the complete loss of all investment in foundations, &c. To prevent such loss in the future, would it not be better to build the majority of central stations on such a scale as will meet the anticipated requirements of electric supply at the end of 20 or 30 years?

Mechanical  
Engineering on Electric  
Tramways.

Mr. A. RECKENZAUN'S paper on "Electric Locomotion," read before the Society of Arts in April, 1887, was probably the most complete *exposé* of the state of the art at that date; therein the subject was considered mostly from a mechanical engineer's standpoint, great care being taken in revealing the advantages or disadvantages of certain mechanical details. It was shown that the spur gearing on certain continental electric cars had worn out in a remarkably short space of time, and that the engineers attached to these lines were puzzling their brains over the best forms of gearing for electric cars. Six months later Mr. Reckenzaun read another paper entitled "Electric street cars, with special reference to methods of gearing," before the American Institute of Electrical Engineers, which evoked an interesting discussion and a variety of opinions. That the problem of the mechanical transmission of power between the motor and axle of a tramcar is still a long way off its solution is evidenced by the report of Dr. W. L. Allen presented to the recent Convention at Buffalo. On four Sprague cars, each running 90 miles a day, there were worn out, within six months ending October 1st, 1890, 14 pinions, 6 spur wheels and 26 bearings of various kinds. On one of the Thomson-Houston electric railways, running 150 to 200 cars there occurred 158 cases of disablement, from purely mechanical reasons, during 14 consecutive days. This would point to the fact that mechanical engineering on electric railways offers a wide field for research and improvement. There are, on an average, six cars disabled mechanically to one electrically. Altogether, the figures are appalling, and we do not wonder that Messrs. Mather & Platt preferred to drive the axles of the City and South London locomotives direct, although, in this case, difficulties of another kind may become apparent, since the acute vibrations of the driving axles are communicated direct to the armature. In the case of tramcars it is most difficult to apply motors of sufficiently slow speed, and gearing of some sort has to be used.

Industrialism.

IN Mr. Esson's presidential address on Industrialism to the Old Students' Association, our readers will find a very able and interesting historical sketch of this important subject from the earliest to the present time. He makes a vigorous onslaught on socialism, State or other; and expresses a decided opinion that what is best in our industrial system is the result of individual effort. His statement, based on personal experience, that the working classes in this country spend from 15 to 20 per cent. of their earnings on beer and tobacco, gives one a somewhat startling idea of the improvidence of the British workman. We think, however, that Mr. Esson overestimates the effect of Poor Laws in encouraging improvidence, since, according to recent statistics, considerably less than one-tenth of the poorest class in London avail themselves of State relief. Mr. Esson thinks that all changes in our industrial system are the result of evolution; the present system with all its defects being the best that the average human nature is capable of. With many other of our most advanced thinkers on this question, he looks upon co-operation as the goal to which we are tending; this being apparently the only practicable means of settling the ruinous contests between capital and labour. Mr. Esson's address, we are sure, will be welcomed by all interested in the labour question, as a carefully weighed statement of the case, by one who has the advantage of

being practically acquainted with the various elements of the problem.

Advertisement—  
fin de Siècle.

THE custom, common to only too many journals, of inserting conspicuous paragraphs, which at first sight appear to be *bonâ fide* items of news, and which upon examination turn out to be advertisements, has become a scandal and a disgrace to present journalism. Our contemporary, the *Electrician*, in a leaderette, calls attention to the case of the *St. James's Gazette*, a journal of some reputation, in whose columns appear, under the disguise of original matter, the advertisements of an "eminent" medical electrician. The paragraph referred to points out that this is a clear case of imposture, and more discreditable to the journal than to the advertiser. We are glad to see the *Electrician* join, although somewhat late in the day, in an attack upon this disreputable phase of journalism.

Render unto Caesar, &c.

IT is sad to see to what extent the manipulators of paste and scissors are allowed to urge on their wild career unchecked. In the last issue of a weekly contemporary entitled the *Practical Engineer*, which, however, belies its name in this instance, we find that famous note culled from the "London Day by Day" columns of the *D.T.*, which has immortalised Earl Poulett and his yacht. If it had given our daily contemporary the credit of originating the wonderful story of accumulator explosions nothing need have been said, but the paste and scissors gentleman has so far forgotten his mission in life that it appears as an editorial note in a technical journal.

Clear Off the Track.

IN a leading article devoted to the opening of the City and South London Railway, one of our contemporaries seems to have gone off at a tangent. Witness the following:—"We very much regret to hear that Messrs. Mather and Platt have contracted to run the trains at 3½d. per train mile for two years. This system has proved disastrous in both electrical and other mechanical tramway work, it has led to all sorts of complications and disputes, and has created antagonism where co-operation is essential. The local authorities themselves have not done so much harm to the development of electric traction as have tramway companies, who have tempted inexperienced inventors to make what they call demonstrations of their systems under this method of contracting at so many pence per car mile." We fail altogether to see any cause for the state of mental perturbation into which the editor of our contemporary has fallen and which has partially obscured his usual clearness of perception. Messrs. Mather and Platt can scarcely be called inexperienced inventors, and if they are satisfied that the power can be supplied at the price named, and the Railway Company accepts these terms, it is difficult to perceive why complications and disputes should crop up. With Dr. Edward Hopkinson's large experience of the Bessbrook and Newry line, Messrs. Mather and Platt are doubtless perfectly justified in the policy they have adopted, for our contemporary seems to forget that the previous electrical work in which "this system has proved disastrous" has always had the accumulator as the unknown quantity in the problem. Moreover, so far as we have been able to judge, the tramway companies have been the tempted, and not the Mephistophelian fiends who lure on misguided inventors to destruction; but, then, perhaps we look at the same things through different coloured glasses.

COMMUNICATIONS FROM AUSTRIA-  
HUNGARY.

[FROM A CORRESPONDENT.]

YOU have already announced the projected electric lighting of the Imperial Palace at Vienna, and the details have since been made known in semi-official circles. The installation, which owes its origin to the decision of the Emperor, will be completed by January 1st, 1891. It will not, however, for the present extend to the apartments of their Majesties, which will not be arranged for this purpose before next summer. There will be put up altogether 4,000 glow lamps, with an illuminating power of 4 to 5 normal candles. They will be introduced in the large reception rooms, consisting of the Hall of Knights, the Ceremonial Saloons, and the apartments for strangers placed behind them; the electric light will also extend to the great Ambassadors' Stairs, the St. Stephen rooms, and a part of the old Imperial Chancery. The large Ceremonial Hall, in which the Court balls are held, will have 1,500 glow lamps. All the old chandeliers, which are at present fitted up for wax candles, will remain, and will serve as mountings for the glow lights, the electric leads being conveyed through wooden pipes well varnished.

The electric lighting of the Royal Hungarian Palace at Buda, which, as I have already informed you, is likewise a decided matter, will not be carried out before next year, since it is feared that the adaptations might not be complete before the date when the Imperial and Royal family will take up their abode in the Buda Palace. Here, also, there will be used 4 to 5 candle glow lamps, about 1,500 in number, and, as in Vienna, they will be mounted like candles in the existing chandeliers.

At Fiume, the International Electric Company is about to erect extensive electric works from which 100 H.P. will be taken by means of alternating current motors for working the newly constructed elevator. The concession granted to the city has already received the sanction of the Municipal General Assembly. But here, also, the gas company is preparing on an equally frivolous pretext with those which I have described to you as having been raised at the Bohemian watering place Teplitz, to contest the right of the town to grant such a concession. I hope shortly to give you very interesting details on this question.

In the little South Hungarian town Karánsebes, the electric works erected by the firm Schmidt and Perlfasser at their own saw mills has come into action, and subscriptions for 500 lamps have already been taken up. This is the first electric works in Hungary for lighting a small provincial town, and has excited a lively interest in the neighbouring towns. It appears very probable that other Hungarian towns will shortly follow the example of Karánsebes.

The firm Müller and Einbeck, recently converted into a joint stock company, has also erected works at Baumgarten, near Vienna, for the manufacture of Tudor accumulators, and is about to open commercial and technical offices in Vienna.

The management of the Royal Hungarian State Railway has resolved to introduce the electric light in their trains, and in the first place in the express trains. At present a train of eight carriages is being experimentally arranged for the electric light, and the results obtained will be accepted as decisive for the introduction of this light on long-distance trains. The experiment will be carried out with accumulators supplied by the firm Müller and Einbeck.

**The Electric Light in Leamington.**—A controversy is in progress between the Corporation and Messrs. Chamberlain and Hookham respecting the quality of the light supplied to the borough. The authorities refuse to pay, and the Birmingham firm demand 5 per cent. on the unpaid account, at the same time stating it is their intention to apply for a provisional order.

A NOVEL COMBINATION ELECTRIC  
SWITCH.

By LIEUT. SAMUEL RODMAN, JUN., U.S.A.

IN presenting the following subject matter, I am led to believe that it may possess sufficient interest and value to warrant at least a passing glance from the readers of the *Electrical World*. Hardly a day passes but some new design in the way of a double or single pole switch is brought out. The one which I have devised, and will describe, is neither, but may better be called a continuous combination switch.

As it possesses certain characteristics different from other switches, I shall first go into a little preliminary detail, in order to make clear its functions and working. Referring to fig. 1, let A represent a strip of metal, and  $b, b', b'', b'''$  and  $b''''$  metallic springs, so arranged that when A is moved up or down in the direction of the arrow, it will successively touch the metallic springs,  $b$  to  $b''''$ , until it reaches a position indicated by the dotted line enclosing  $A'$ , when it will touch all five of the springs,  $b, b', b'', b'''$  and  $b''''$ . Move the metallic

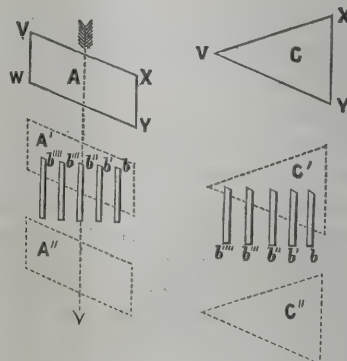

FIG. 1.

FIG. 2.

strip now to the position indicated by the dotted lines enclosing  $A'$ , and it will be seen that it will slide past the metallic springs in the same order that it moved on to them. So, taking the movement in detail, we have the metallic strip first touching the spring,  $b$ ; then  $b$  and  $b'$ ; then  $b, b'$  and  $b''$ ; then  $b, b', b''$  and  $b'''$ ; then  $b, b', b'', b'''$  and  $b''''$ ; then  $b', b'', b'''$  and  $b''''$ ; then  $b'', b'''$  and  $b''''$ ; then  $b'''$ , and finally sliding past all of them.

Referring to fig. 2, let C represent another strip of metal, and  $b, b', b'', b'''$  and  $b''''$ , as above, metallic springs. Move C in the direction of the arrow to positions indicated by the dotted lines enclosing  $C'$  and  $C''$ , and it will be seen that it will successively touch the metallic springs from  $b$  to  $b''''$ , and will slide past them in exactly the reverse order from  $b''''$  to  $b$ . Taking this second example in detail, we have the metallic strip, C, first touching the spring,  $b$ ; then  $b$  and  $b'$ ; then  $b, b'$  and  $b''$ ; then  $b, b', b''$  and  $b'''$ ; then  $b, b', b'', b'''$  and  $b''''$ ; then  $b', b'', b'''$  and  $b''''$ ; then  $b'', b'''$  and  $b''''$ ; then  $b'''$ , and finally sliding past all of them.

By giving different shapes to the metallic piece which slides on and off the springs, other different combinations could be brought about; but the two general cases given will show that for the five springs taken there are nine different combinations of contact between the metallic piece and springs; or taking the more general case, and letting  $n$  represent the number of metallic springs, the different combinations of contact between the metallic piece will be represented by the general expression  $2n-1$ .

For a simple case to show how such an arrangement as I have described will apply as an electrical switch, I will refer to fig. 3, which represents a dynamo, one pole of which is connected to the metallic strip and the other to one terminal of each of a group of five lamps, the other terminal of the lamps being each connected to one of the metallic springs,  $b$  to  $b''''$ , as in fig. 1. Now,

suppose A to be moved in the direction of the arrow head, and, from contact with *b*, lamp C will burn; then, from contact with *b* and *b'*, lamps C and C'; then, from contact with *b*, *b'* and *b''*, lamps C, C' and C'', and so on until A has moved past the springs and no lamps are burning. By this arrangement, then, we have 1, 2, 3, 4, 5, 4, 3, 2, and 1 lamps burning, or, in other words, we have varied the intensity of the light gradually and continuously. The example taken of the continuous gradation of light is presumably the simplest case. Many other applications may be made, substituting for the single lamps different coils of a shunt-wound dynamo or motor, or groups of lamps.

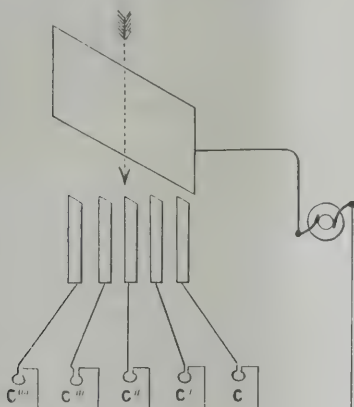

FIG. 3.

The number of metallic springs chosen in the figures is five, but it can readily be seen that by increasing the size of the metallic strip A, fig. 1, and C, fig. 2, almost any number of metallic springs can be accommodated, and also a greater number of circuits controlled continuously and successively.

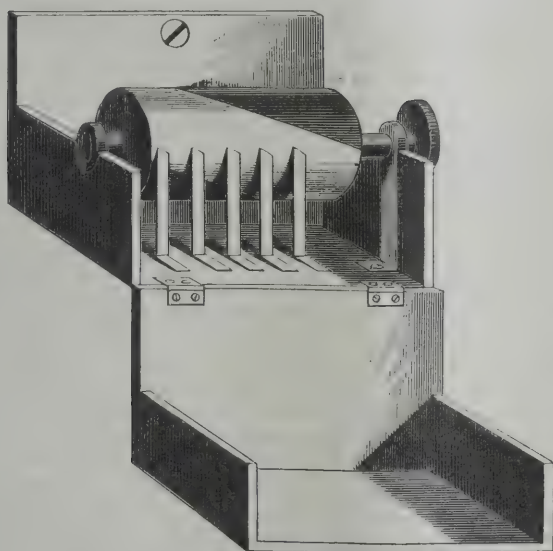

FIG. 4.

As a suggestion to those interested in the subject, I would propose the use of such a switch in connection with a shunt-wound motor on electric cars, in order that the current from the main dynamo may be thrown into the motor coils successively, increasing gradually the number of ampère turns, and possibly overcoming the difficulty and strain experienced in starting a heavily loaded car from a state of rest, and lessening the number of burnt-out armatures. By the use of such a mechanism no resistances are necessary, but the increments of current are supplied successively by a simple mechanical arrangement.

To resolve the mechanism above-described into an electrical switch, I simply make one mechanical change,

and that is, to transform the motion of translation of the metallic piece A, fig. 1, and C, fig. 2, to a motion of rotation about an axis, and the following description of the switch will be sufficient explanation:—

A cylinder of insulating material having a metallic axis is first made. A thin flat metal strip shaped like A, fig. 1, or C, fig. 2, is then cut out and wrapped around the cylinder, the sides V, W and X, Y of A, and the point V and the side X, Y, of C, coinciding with the two opposite circular edges of the cylinder, thus forming a helical plate. The plate is secured to the cylinder by metallic screws which project through to a good contact with the axis. The latter revolves in a metal bed or bushing, and is held firmly by caps. The whole arrangement is set in a box of peculiar construction, as shown in fig. 4. The metallic springs are attached to the bottom of the box, and press firmly against the cylinder. On the under side of the box are binding posts, one to each metallic spring. The terminal of the dynamo is led in through the bottom of the box and screwed to the metallic strip shown on the right side of the box. This strip is maintained in metallic connection with the helical plate on the surface of the cylinder by means of the metallic bushing, axis, and screws connecting the helical plate with the metallic axis. The screw seen at the top of the box is intended to fasten the whole arrangement to the wall. It will be seen that the box can be readily closed and opened without removing it from the wall; also that by taking off the caps over the axis of the cylinder the latter may be removed and the switch thereby rendered inoperative, so that the connection of the wires will not be attended with any danger. I think, at least, it can be claimed that the whole apparatus is very simple for one which combines so many different functions in so small a space.

## THE CIVILIAN ELECTRICIAN IN MODERN WAR.\*

By LIEUT. BRADLEY A. FISKE, U.S.N.

I BEG to propose for your consideration this evening a plan by which, in time of war, all the electrical resources of New York, both in supplies and in men, will become at once available for the defence of the country and the city.

It is well known to all here that electricity has come into use as one of the great factors in warfare, both on sea and shore, not as an adjunct merely, as for lighting ships and forts, but as a vital element in the handling of weapons in actual battle, and in the construction of new instruments which accomplish things heretofore impossible.

I desire to recall to your recollection a few of the most important uses to which electricity is now put in warfare, to indicate some of the probable paths of future development to show that it would be impossible for our regular navy and army to adequately handle the vast electrical work that would have to be instantly done in time of sudden war, and to suggest a plan for coming to their assistance.

The science of electrical engineering is now recognised as one of the most necessary of the practical sciences of the world. It stands out as distinct and defined as the science of medicine, or the science of astronomy. It enters into thousands of the departments of daily life, but into no other department is it used in so various and important ways as in warfare. This is so much the case that the prophecy is sometimes ventured that in the near future nations will fight by electricity. Though this, like all extreme statements, requires modification, yet the number of ways in which electricity has come to be applied within the last eight years is calculated to inspire the liveliest an-

\* A paper read before the N.Y. Electrical Society, October 23rd 1890.

ticipations as to the developments of the next eight years. No vessel pretending to modern equipment goes to sea without a complete electric plant for furnishing light. This light is so much more suited to ship life than any other light that we now wonder that we ever went to sea without it. The electric motor is coming into use for ventilating ships, and it is beginning to be used for training guns and the hoisting to the deck of shot and shell. The best and the most accurate results at target practice are attained when the guns are fired by electricity. Range finders give the gunner constant knowledge of what he must know, *i.e.*, the distance of the enemy. The best means of night signalling, and the one adopted in nearly every navy in the world, is by means of incandescent lights. The electrical search light is almost as much a feature of the equipment of a modern war ship as are her guns and her torpedoes. In the actual use of the Whitehead and Howell torpedoes electricity plays an important part. The telephone is now coming into use for ship work, and will unquestionably supplant the speaking tube, which is acknowledged in all navies to be unsatisfactory. In fact, we find all through modern war ships an increasing use of electricity. The reason is clear. The modern war ship is the most intricate, tremendous and powerful machine existing. In no other equal space can be found so many, so various, and so important kinds of apparatus. Everything must be done which will put her absolutely within the grasp of the captain. She must respond at once to his command, and her whole strength and power must be his, as though she were a part of him. Ensconced in his armoured conning tower he must be the brain of the gigantic body. Electric wires must convey instant tidings to him from her innermost recesses, and electric wires flash back from him the inevitable command. In this way only can a modern ship, no matter how large, how strong, how heavily armoured, or how swift, completely fulfil her mission and be a perfect fighting machine.

What is true of ships is equally true of forts. The power of ships' guns has so increased that it has become necessary to protect shore batteries by iron and steel instead of masonry, as in the days not long gone by, and, in addition, to use disappearing carriages wherever it can be done. Disappearing carriages, as is well known, are so arranged, that the gun disappears below the parapet of the fort when the gun is fired, and remains out of sight and safe during the operation of loading, so that it is exposed only for a short time when it is raised to fire. Now, without the aid of electricity, a very considerable time would elapse, even after the gun was raised, before it could be fired, because the gun would have to be trained in the proper direction and be elevated to the proper degree for propelling its projectile over the distance between it and the enemy. To estimate this distance and make the proper adjustments would entail delay, and would be absolutely impossible if smoke obscured the target, as would be the case a great portion of the time. But electricity, acting through the medium of the position finder, gives the gunners continuous information of the distance and direction of the enemy, no matter how thick the smoke, so that they know exactly what to do before the gun is raised to fire.

Electricity, furthermore, gives the commanding officer complete control of all the different groups of guns and mortars in his fort. Noting the progress of the action from a station aloof from the smoke and noise, he can direct the concentration of as many batteries as he thinks best on one ship, or can disperse the fire as much as circumstances from time to time dictate.

For the handling of the monster apparatus used in forts, the guns, the carriages, the ammunition, electricity is rapidly coming to the front. Some power must be used, since the muscles of men are too weak. Hydraulic power has been used hitherto; but for many purposes electricity has the same advantages over hydraulics that have caused its unprecedented advance in the other departments of engineering throughout the world; while for repelling a night attack from ships,

the search light has been found, by repeated trials in the naval manœuvres abroad, to be simply indispensable to the land defence.

For military service in the field there is not an army in the civilised world that has not its military telegraph service. One great cause of the suddenness and completeness of the German victory in 1870, was the rapid mobilisation of the Prussian army, and its appearance on the frontier ready for battle. Now the splendid efficiency of the telegraph service in the hands of the military authorities made this possible. Nothing is more important in warfare than despatch in moving the enormous bodies of men, of which modern armies are composed, with all their ammunition, equipments, and numberless accessories. To move a quarter of a million men to the frontier in a single day, means a good deal; and to manœuvre so large a body of men with such precision and rapidity that no one division shall have to wait for any other division, simply cannot be done without electricity.

But the most immediate and important use of electricity in the defence of a coast is in the submarine mine or ground torpedo. Defending a harbour with submarine mines is simply carrying out with more or less elaboration a system by which a large number of watertight tanks, each holding from 100 to 1,000 lbs. of gun cotton or other explosive, are anchored in carefully defined positions, and connected by armoured electric cables with protected operating rooms, in which are batteries, measuring instruments, &c. The more complete mines have usually floating above them automatic circuit-closers, in which two contact points are joined together by a passing ship, and thus afford a passage for the electric current to the fuse in the torpedo.

Now these mines are some of them exceedingly large and heavy, and the electrical apparatus, while simple to the mind of a trained electrician, yet must be made and adjusted with great care. The torpedoes as a system must be constructed, laid down, and connected to the operating rooms on shore by long and heavy armoured cables. The operation of practically planting and connecting the necessary submarine mines for New York would be a stupendous undertaking. Kindly bear this in mind until I recur to it again.

We have now seen, after a rough survey of the subject, that electricity has already acquired an acknowledged position in the art of war, and that the uses to which it is put are not trivial ones. Electricity is not used in warfare as a convenience, nor is it a fad of theorists; it fires the guns, it discloses the stealthy approach of the torpedo boat at night, it directs the proper elevation of the guns; in fact, it does good, honest, practical work. But note this point also: in every one of these applications of electricity we have to pay, in one way, for what we get, by studying the ways in which electricity will work for us. We cannot expect electricity to work for us unless we treat her properly. We cannot handle electrical apparatus with carelessness and ignorance, and expect that it will work when we need it. In other words, we find in warfare, as in everything else to which electricity is applied, that electricians are useful. This remark doubtless seems absurdly commonplace, but it is intended to suggest that, in war time, electricians, even civilian electricians, may suddenly become very useful to the Government. A captain of a fine ship might lose an action from simply a lack of knowledge as to some electrical appliance on his part, or on the part of some subordinate; some small accident might break a circuit just at a critical juncture, which might prevent the communication of an order, the receiving of information, or the firing of a torpedo at a crisis; and yet the cause might be such, that a man with even a very slight knowledge could remedy the difficulty in a second by the mere pressure of his finger; but that pressure not being given, the action might be lost, and from that cause alone.

Let us now glance at some of the other uses of electricity to which it would probably be but in case of an attack upon New York. There can be no reasonable doubt that Lay torpedoes, Patrick torpedoes, Sims-

Edison torpedoes, and Halpine-Savage torpedoes would come to the front at once. The enemy's fleet being daily expected off Sandy Hook, we should see the advocates of these systems, under authority of the general government, preparing stations at Coney Island, Sandy Hook, and elsewhere, for the launching of their dreadful missiles against his ironclads. The question of ballooning, both for observation and for the dropping of explosives on his decks, would be taken up at once, and the electrical world would be agitated anew over the question of balloon propulsion by electricity. Electric launches, ranged to carry torpedoes, would be fitted out to noiselessly steal out at night on their errands of destruction. Electric picket boats of smaller size, perhaps, would scout the waters in pursuit of information, or to convey despatches; electric submarine boats would spring into being by the dozen, and, filled with adventurous spirits, would seek the enemy, secure from detection below the surface of the sea, and carrying enough explosives to utterly destroy the proudest war ship of the world.

It will now be apparent that in the case of a sudden war (and most wars are sudden), there will be an immense amount of work to be done in the electrical line alone. Could our regular army and navy do all this work in the time allowed? It is probably known to all here that our regular army and navy are simply a nucleus around which fighting forces could be formed. They are so small as regards both officers and men, that they can barely carry on the work in time of peace, and would be wholly inadequate in time of war. We should not have enough battle ships, monitors, cruisers, or torpedo boats; we should not have enough forts; we should not have enough sailors; we should not have enough infantry; we should not have enough artillery; we should not have enough electricians. Take the single matter of laying out and connecting up the submarine mines in New York harbour. This is an area covering many square miles, in parts of which the mines would be placed at frequent intervals; every mine being accurately secured in its designated place and connected by cable to the operating room, perhaps miles away. The mere labour of constructing, fitting and filling one mine, and afterwards taking it out into the harbour and lowering it into place, with all its connections, is no small task; and what can be said of the task of doing this with hundreds of submarine mines? Then the work of properly arranging the various cable connections, testing apparatus, firing apparatus, &c., necessary for the efficient action of the mines would follow. The Board on Ordnance and Fortifications have designed all the torpedo defences, but they will not be in practical operation, probably, for many years, and a war may come meanwhile. But it is certain that on the outbreak of any war an immense amount of this work would have to be immediately done, because we will never keep the submarine defences of New York harbour on a war footing in time of peace.

The Navy Department would be even more hurried. We should certainly be called upon to commission a great many war ships, and to equip as commerce destroyers a great many merchant steamships; we should have to do all the things that we did on the outbreak of our last war, and in addition, we should be confronted with the necessity of fitting all kinds of fine apparatus, the necessity of fitting electrical appliances of all descriptions, besides securing gun-circles in place with mathematical precision, and of accomplishing all the manifold fine work that is required with the ordnance, navigation and engineering equipment of a war ship of the present day. And as to fitting on merchant ships, who is going to fit them out? This operation requires technical knowledge. Who has it? How many of the merchant steamship captains would be able to install and manage a battery of even Hotchkiss or Driggs-Schroeder guns, or could remedy an accident to either gun or ammunition?

It being apparent that the regular army and navy in event of a sudden war would be unable to handle all the electrical work that would certainly be thrown upon them, I will propose the formation of a corps of

naval and military electricians to assist the regular army and navy in its work. Such a corps might exist in every principal seaport town on the coast; the principal one, of course, being the corps with headquarters in New York. Electricity being now a recognised factor in both naval and military war, and requiring expert electricians for its full development, there would seem to be just as much reason for an electrical corps in the National Guard of the State of New York as for infantry, artillery or cavalry. While the members of this corps would be men of technical knowledge, and while its sphere of usefulness in war would be because of that technical knowledge, it is obvious that the organisation should be a military one, and that with some modifications it should be governed by the same principles as govern all military bodies. Being a military body under the Governor of the State, it could at once become available at the outbreak of war.

It would seem that this corps, like all other corps, should be composed of men of various ranks, subject to various duties. Many kinds of work would have to be done in war, and many kinds of men would be required to do them. On the outbreak of war, certain members would naturally elect duty in the navy; others in the army. The most obvious and immediate employment would doubtless be in the torpedo defence of the harbour, under the direction of the general commanding. And who can doubt the gratification which that general would feel, when suddenly ordered to defend New York Harbour, on finding added to his list of subordinates a hundred or more capable electrical engineers, young, enterprising, accustomed to difficult electrical work, familiar not only with electricity in its technical features, but also acquainted with the electrical people of New York, with its factories, its places of business, and its methods of business. These men would become available in a day, and could be at once set to work in carrying out the details of the vast and complicated system. Their work need not be confined to that purely electrical in character, because every electrical engineer is, by training and of necessity, a mechanic, and every sort of apparatus would be readily understood by him, and a very slight training will make him master of it. Those members volunteering for naval work would be equally useful. The ordnance officer at the Navy Yard would suddenly find himself overwhelmed with a mass of work which he would be utterly unable to carry out without the assistance of some such sort as this. And for the reason that electrical engineers are of necessity mechanics, a great deal of technical work could be entrusted to them, such as the arrangement and fitting of gun carriages, the storage of ammunition, the assembling of guns, &c. Their more immediate and obvious field, however, would be the installation and fitting of electric lights, motors, telegraphs, telephones, and other electrical appliances on board the vessels of war suddenly called into requisition. In the matter of fitting out merchant steamships their usefulness would be at once apparent. The number of regular officers would be found utterly out of proportion to the number of ships; the whole navy would have to undergo an expansion. Only a very few regular officers could be assigned to each vessel; so that the majority of officers would have to be volunteer officers, as was the case in our Civil War. During the first part of the war the command of the different vessels would naturally be intrusted to regular officers leaving the other positions to be filled by volunteers. Now, as the commander of a ship is head of all the departments of a ship, he cannot give much personal attention to one special department. Therefore, the general arrangement and fitting out of all vessels, both regular war ships and merchant steamships, would have to be largely entrusted to volunteers in all that relates to the electric and ordnance equipments. Now, as the work of fitting out ships with electric and ordnance equipments calls for technical knowledge and experience of a high character, it is obvious that a corps of well-trained technical men, such as here suggested, would be more than useful, they would be necessary.

A further field for employment of such a corps in time of war is suggested by the fact that the genius of our people tends towards constant invention and improvement of all sorts of machinery and apparatus, and our history has shown that every war has brought into being many inventions in weapons of defence and offence. Can it be doubted, then, that any future war would produce more such inventions? And in view of the great progress of electrical science since the last war, and in further view of the large number of electricians in New York, can it be doubted that many of these inventions would be electrical in character? Under the stimulus of a national peril, and with the resources of New York at command, it is certain that important and novel warlike applications of electricity would at once spring into being. And while our regular forces of both army and navy were employed on their specific duties, what more natural than that some new Ericsson should arise, and some new "Monitor," or other craft, startle the nations of the world? Therefore, besides the obvious uses to which such a corps as this might be placed, there are other uses, no less important, of inventing, constructing and using weapons of defence, the nature of which we cannot as yet even faintly conceive. And as few heroes of our late war go down to history with more glory than has Ericsson, so, perhaps, our next war may produce some electrician now unknown, whose fame will outlive the ages.

It would seem as if such a corps as this could be formed under existing laws, and that there would be no difficulty in enlisting members. The attractions of the Naval Reserve and of the National Guard seem sufficient to induce a large membership in the different regiments, and there is no reason why membership in an electric regiment should not be equally desirable and confer equal distinction. The qualifications for entrance as regards education and intelligence, would be greater than those for any other regiment, corps or battalion. Its military and naval usefulness would be acknowledged, and its position in all respects would be one of dignity. The larger the membership, the better, provided, of course, that due care be observed in excluding undesirable persons. The whole electrical influence of New York and of the country would be at its back, with all its millions of dollars and its men of world-wide fame; and there is no reason why it should not acquire a national influence. The course of instruction could be readily carried out, embracing the naval and military applications of the purely technical science, with which the members are already familiar, instruction being given by regular navy and army officers detailed for the purpose. This instruction would naturally embrace the construction and care of apparatus. It being presupposed that there are different ranks in this corps, the system of instruction will naturally differ with the different ranks. With the higher ranks, it would naturally embrace the theory and practice of gunnery, navigation, including compasses, and seamanship. Steam engineering would probably not need to be taught, it being assumed that the members require very little instruction in that branch. For the lower ranks the scheme of instruction need not include much more than the handling and care of the different apparatus. On the outbreak of war the members volunteering for the different services could be subjected to certain examinations, and their rank determined by the proficiency exhibited. As to the details of organisation, uniform, &c., these need not be entered into here, as they can obviously be settled at any future time. My only purpose now is to propose to you a plan for meeting an emergency, which may some day arise. I would hazard the suggestion that the corps or battalion should at first include about 250 members, and that it should be officered, uniformed and drilled in much the same ways as the other corps of the National Guard. I would even advocate a certain amount of infantry drill as a means of instilling the military idea. Occasional runs in the torpedo boat *Cushing*, and frequent short trips out to sea for target practice in modern war ships, would be essential. There would be considerable work, but there would be

many compensating social and other advantages. I have ventured with much diffidence to put forward this idea, but earnestly hope that you will think it worthy of earnest consideration. My only excuse for broaching it is that it has been in my mind for many years, that it has been commended by every man to whom I have spoken about it, and that I have been urged to bring it to the attention of the electricians of New York.

### THE PARIS TELEPHONES.

THE new service of telephoned messages began working on the 3rd inst. On the morning of that day, the Administration of Posts and Telegraphs posted up the following notice:—"On and from the 3rd November, 1890, the public is allowed to send telephoned messages to any address included in one of the streets situated between the Seine and the grand boulevards. The price is fixed at 50 centimes per five minutes' occupation of the cabin. The length of occupation is limited to a maximum of ten minutes, when others are awaiting their turn of communication. For the transmission of messages, communication can only be demanded directly by the sender." Thus a telegram can now be telephoned, provided one is within the radius served by the ten telegraphic offices situated between the Place de la Concorde, the Seine, the grand boulevards, the Place de la Bastille, and the Boulevard Henri IV. He can telephone from any point, but only messages for persons living within the above-mentioned radius will be admitted. If this attempt succeeds, it will be successively extended to the rest of Paris, and also to the suburbs.

The following are a few details of the new central telephone office which is being built on land between the Rues Gutenberg, Jean Jacques Rousseau, and du Louvre, with its principal frontage to the Rue Gutenberg. The ground floor will serve as a standing place for the vehicles of the postal authorities. On each of the four floors will be found a large hall, 60 metres long by 10 wide. In these halls will be placed the apparatus, which will enter the building in the cellar through the sewers, and will be distributed between the four floors, which will share the telephonic transmissions and receptions of the four zones of Paris.

Our Parisian contemporaries keep up a running fire of comment, sarcastic and otherwise, on the telephone working in Paris. One of them, for instance, relieves itself as follows:—"The service of pneumatic tubes is decidedly as defective as that of the telephones. It is thus that a *carte-télégramme* registered at 11.35 on Friday morning at the Bourse office, was delivered at five minutes past four in the afternoon at Montrouge. This fact is noticeable at a time when the trial of telephoned messages is going to call upon the deplorable services of the telephones and the pneumatic tubes to lend assistance.

There has also appeared in the *Journal Officiel* a decree which creates, for the night, a conversation tariff at reduced price in the interurban correspondence service. This tariff is fixed per unit of telephonic conversation, and per 100 kilomètres or fraction of 100 kilomètres of distance between the points joined by the telephone line, at 30 centimes for ordinary conversations, and at 20 centimes for conversations by subscriptions. The subscription includes the daily use and at a fixed hour for a five minutes' conversation for a circuit specially designed, the minimum duration being one month. The subscribers obtain communication at the precise moment provided there is not a conversation on between two other persons. The time not used at one conversation cannot be carried over to another, save and except the non-use be due to an interruption of the service. After a first interruption of the service of 24 hours, there is to be returned to the subscriber, for each further period of 24 hours, a thirtieth

of the amount of the subscription. The circuits over which this reduced tariff is to be applied and the hours during which the conversations may take place under this decree will be determined by ministerial warrant.

### STREET RAILWAY MEN AT BUFFALO.

ELECTRICAL engineers have again been enthusiastic over the cordial reception they received from the American Street Railway Association, which held its ninth annual meeting at Buffalo, N.Y., during the week ending October 17th. Mr. Thomas Lowry presided over an assembly of nearly 500 gentlemen interested in every branch of street railway business, and he opened the proceedings with a pithy address, setting forth the general progress of tramway building and tramway working in the United States. Mr. Lowry pointed out that in the smaller cities electricity is generally being adopted, and there are already about 1,600 miles of electric railways in operation; but municipal corporations in the large cities, with the exception of Boston, are slow to grant new privileges. He hoped, however, that when the people understand clearly the great benefits of rapid transit, by electricity or other improved motive power over horses, they will demand that their city authorities grant such rights as will enable street railway companies to operate by the most approved methods. From these remarks of the President one would naturally infer that in large cities electric traction *per se* has been objected to, but we know it as a fact that such is not the case, and that systems devoid of overhead conductors have actually been encouraged by the authorities who are merely anxious to get rid of overhead wires in general.

The first communication was a "Report on Electric Motive Power Technically Considered," by Dr. W. L. Allen, which fully discusses the various electrical and engineering details of an electrical railway. This is a thoroughly practical paper, showing up the defects which have been made manifest during prolonged operation, and it suggests sensible remedies in several instances. The author gives a list of breakdowns which occurred at various periods on one of the Thomson-Houston roads, and he shows that most of these were of a mechanical nature. During 14 consecutive days in July last, out of 150 to 200 cars in operation, 26 were disabled through electrical defects, and 158 breakdowns of a mechanical nature occurred. From this it appears that about 1 per cent. of the cars operated were disabled each day from electrical causes, and about 6 per cent. from mechanical causes. As the report does not state the nature or degree of electrical disablements, it is not fair to assume that they were all due to crippled armatures. All that can be deduced is, that a car may run 100 days without electrical repairs, and only 17 days without mechanical repairs; the cost of this is not stated. In the case of four Sprague cars running on another road, the repairs for six months have cost \$1,191. On these four cars were worn out, 3 bronze pinions, 11 steel pinions, 6 spur wheels, 6 axle brasses, 8 shaft bearings, 12 armature bearings, 180 carbon brushes, 6 trolley wheels, and burnt out 3 field magnets and 6 armatures.

"Public and State Treatment of Corporations," formed the theme of a paper by Mr. G. H. Scribner; this, though interesting, and in some points applicable to our own municipal institution, scarcely comes within the province of an electrical journal. Mr. D. H. Bates read a paper on "The Edco Storage Battery Car," enumerating the conveniences of self-contained cars, and the disadvantages of systems having overhead and underground conductors. There is nothing novel in this paper, and the figures on the cost of traction by means of the Edco system are, of course, hypothetical. The discussion, however, brought forth the interesting fact that various storage battery cars are now being introduced on several new lines, and additional ones put on existing lines.

Mr. Carruthers Wain, of London, was one of the guests at this Convention, and when called upon by the President, gave a description of the accumulator cars which are being tried on the Birmingham central tramways. He stated that during the time the electric cars were in process of construction, the receipts on the horse cars amounted to \$600 a week. Immediately the electric cars were put on, the takings jumped to \$1,250 a week. This was not due to any additional service, because it is precisely the same; not to any increase in population, because it has not grown so rapidly, but simply to the fact that they had been able to put on, in place of the wearisome horse car, a comfortable car moving by electric power. Mr. Carruthers Wain concluded in saying that the question of profit on the workings of the storage battery is not a matter of speculation, but is a matter of dead certainty.

### THE PRESENT COMMERCIAL POSITION OF ELECTRIC LIGHT COMPANIES.

THE present position of the various English electric light companies, from a commercial point of view, is not very satisfactory, and the thought has not infrequently arisen in the minds of some shareholders as to whether they might not have invested their money to greater advantage. It was, however, not to be expected that during the first few years of working the dividend paying stage would be reached, although, in two instances, the statements made in the prospectuses were rather too confident of quick returns—a policy which cannot be too strongly deprecated. Nevertheless, the different metropolitan companies are now settling down steadily to work, and in the course of another year or two, it is possible that the anticipations of the shareholders will be realised, at least, to a certain extent.

It may, however, perhaps be interesting to review the present commercial position of the companies, and to consider their future prospects. Taking the London companies in the order of their share capital, the following table shows the names of the companies, the nominal share capital, the amount paid up, and the approximate number of lamps supplied with current.

Name of company.	Nominal capital.	Amount paid up.	Approximate number of lamps supplied with current.
London Electric Supply Corporation ... ..	£1,250,000	£654,690	40,000
Metropolitan Electric Supply Company ... ..	500,000	201,583	40,000
House-to-House Electric Light Supply Company ... ..	350,000	36,610	10,000
Westminster Electric Supply Corporation ... ..	300,000	18,000	6,000
Kensington and Knightsbridge Electric Light Company ...	250,000	49,780	20,000
Chelsea Electricity Supply Company ... ..	100,500	50,000	20,000
Notting Hill Electric Lighting Company ... ..	100,000	14,734	...
St. James's and Pall Mall Electric Light Company ...	100,000	26,090	21,000

It has not yet been ascertained how much of the gross revenue is absorbed by working expenses, depreciation, &c., but these items are estimated by two companies to amount to about 50 per cent. of the total receipts. This percentage may possibly be considered to be high, being in fact slightly less than the working expenses on an ordinary railway, where they are naturally considerable. The annual income derived from an 8-C.P. lamp installed is variously estimated at from 10s. to 14s., or an average of 12s.; and from an 8-C.P. to a 16-C.P. lamp, £1 per lamp. We will, however, take an

average of these two, namely, 16s. per lamp installed. It will, therefore, not be difficult to estimate the average number of lamps which must be in use throughout the year to enable the companies to pay a dividend of 5 per cent. on the total paid capital, providing, of course, that the working expenses, &c., do not exceed 50 per cent. of the gross receipts. For instance, the London Corporation would have to supply about 80,000 lamps, although, considering the excessive cost of maintaining such a huge station, this number would doubtless have to be increased by probably 50,000 lamps.

The Metropolitan Company, with one-third less of paid-up capital than the London Corporation, would only have to furnish 30,000 lamps, while the House to House Company, with its present number of lamps in use, should afford a fair return at the end of the next financial year. The company, which is expected to yield probably the best return on the invested capital is, however, the St. James and Pall Mall Company which, in a remarkably short period, has obtained customers to the extent of about 21,000 lamps.

It might be supposed from the figures given in the table regarding the paid up capital and the present approximate number of lamps alight, that some of the companies are already in a position to declare a dividend. This assumption is, however, incorrect. The number of lamps stated are those which are at present in use, but these must be the *average for the year* to yield any return; moreover, since the figures concerning the paid up capital were compiled, more calls have been made on the shareholders. Thus the approximate number of lights which would have to be supplied as previously stated would have to be increased by, say, 20 per cent. It may, however, be concluded that the commercial position of the metropolitan electric light companies is gradually improving, that in the course of a year or two the dividend-paying stage will be attained, and that the shareholders may rest assured that their investments are assuming a form of stability.

A. W.

### THE PRENTICE MAGNETIC CUT-OUT.

THE accompanying illustrations represent a new magnetic cut-out, which is being placed on the market by Mr. Napier Prentice, of Stowmarket, Suffolk. The cut-out comprises an electro magnet wound with wire, in-

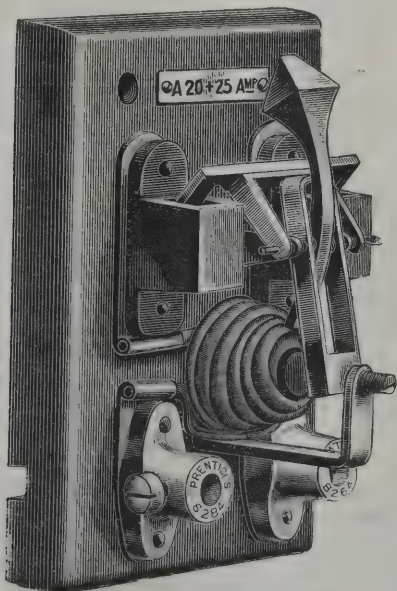

FIG. 1.

cluded in or taken as a shunt from the circuit to be controlled, the external wires being secured by the binding screws shown. These screws are arranged on conducting pieces, one being electrically connected

with the conducting piece carrying the mercury cup on the right, and the other being similarly connected through the coil of the magnet with the conducting piece carrying the second mercury cup. Into these cups dip the ends of the horizontal bridge piece, which is provided with arms carrying the armature. These arms are connected by a cross piece extending behind the vertical lever, which has a counterbalance weight at its upper end, and a tail piece constituting a kicker. The screw shown in front of the armature permits of the position of the latter relatively to the end of the

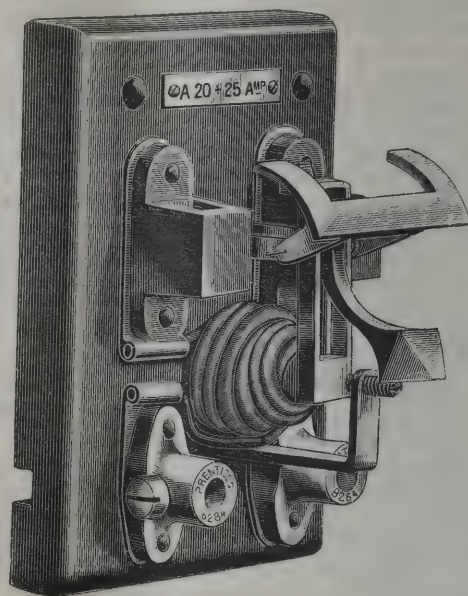

FIG. 2.

magnet core being adjusted. The parts are mounted upon a base of enamelled slate. When the normal current is passing, the armature, bridge, arms, and lever remain as shown in fig. 1; but on the current increasing abnormally, the electro-magnet attracts the armature and the cross piece moves the vertical lever so that its weighted head causes it to fall over in such a manner that its tail end kicks the bridge and knocks it over into the position shown in fig. 2, thus removing the contacts out of the mercury cups, and breaking the circuit.

### GOOLDEN AND CO.'S STEAM DYNAMO.

WE illustrate in our present number a steam dynamo constructed by Messrs. W. T. Goolden & Co., which differs in some essential features from the common arrangements of dynamos, coupled as in this case to Willans engines.

The steam dynamo illustrated is one of a series constructed for the St. John's Wharf Central Station of the Westminster Electric Supply Corporation. It will be noted that the oertype pattern dynamo has been adopted, this being, in the opinion of the makers, a superior arrangement in all cases of dynamos not exceeding 50 kilowatts output, the armature being readily removable without taking away any part of the field magnets, and the brushes, both upper and lower, being readily accessible.

The dynamo itself has the field magnets of wrought iron, bored out to receive the armature; these are bolted to the bedplate, which forms the back yoke of the magnets. The bore of the fields is so arranged as to allow a greater clearance at the lower part than at the upper, thus doing away with a slight downward pull due to unequal distribution of magnetism in the upper and lower half of the armature.

The outside end bearing of the dynamo is mounted in a spherical seating, to allow it to adjust itself in the event of uneven wearing of the different bearings, and prevent any strain being thrown on the shaft.

The armature is a special pattern of bar armature, which has been adopted by Messrs. W. T. Goolden and Co., the bars themselves being laminated, and connected at the ends by a "solid built" armature end composed of V-shaped radial strips, built and insulated with mica, after the manner of a commutator, in combination with spiral strips, also separated and insulated with mica.

The armature end built in this manner, which presents the appearance of a solid disc, is mechanically very strong, and prevents the ingress of dirt or wet, which often affects the insulation at the ends.

The field magnets are internally, as well as externally, ventilated.

The brushes are of Messrs. Goolden's patent type, having screw feeds, enabling them to be fed forward whilst running, without unslacking any nut or screw.

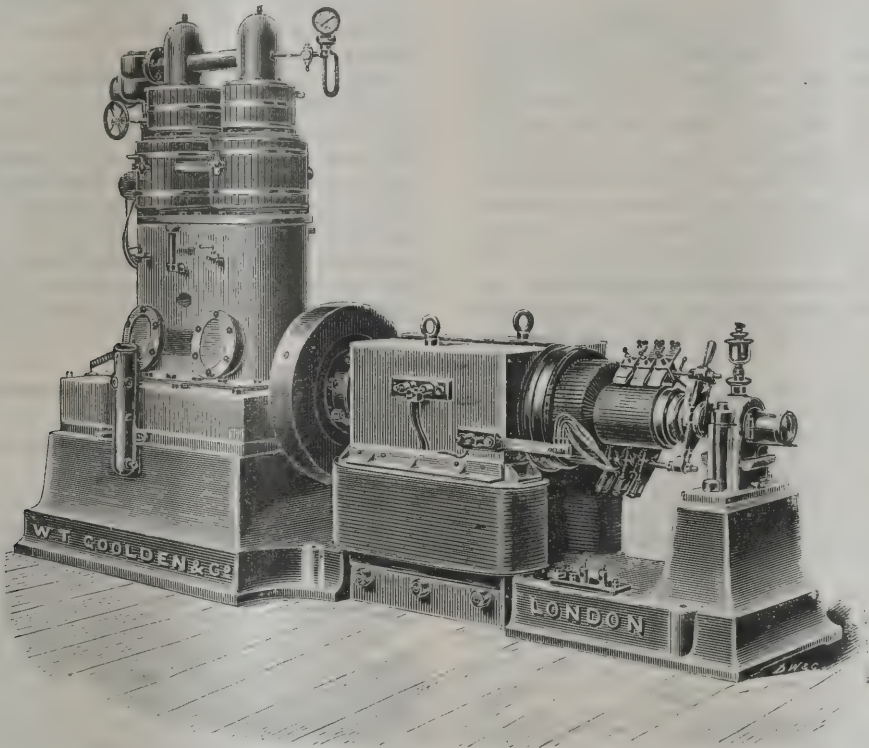

2. The armature shaft and core were put in place, no windings being on, and running with the fields unexcited 9.92 I.H.P. was recorded, equivalent to 1.49 I.H.P. for the shaft.

(It is to be noted that this is excessive, as the bearing at the time was running hot.)

3. The core being in, the fields were excited, and 11.56 I.H.P. recorded, the loss in the core being thus 1.64 I.H.P.\*

4. The armature was wound, and another test made, first unexcited then excited, and deducting the value for the losses in engine, shaft and the core previously ascertained, the loss in Foucault currents in the bars was found to be .34 I.H.P.

The experience and experiments of Messrs. Willans show that the frictional loss in the engine is nearly independent of the load. Hence, from the above figures,

COMMERCIAL EFFICIENCIES OF DYNAMO AND STEAM DYNAMO.

I.H.P. reduced to watts.									Output in watts.			Efficiency.	
Proportion of full load.	Loss in shaft.	Loss in core.	Loss in bars, eddy currents.	Loss in armature resistance.	Loss in field magnet coils.	Total loss in dynamo.	Loss in engine.	Total loss in dynamo and engine.	Volts.	Ampères.	Watts.	Commercial efficiency of dynamo.	Commercial efficiency of combined engine and dynamo.
1	290	1,220	254	1,820	660	4,244	6,300	105,44	120	375	45,000	91.2 p.c.	81 p.c.
$\frac{1}{2}$	290	1,220	254	520	660	2,944	6,300	92,44	120	200	24,000	89.1 p.c.	72.2 p.c.
$\frac{1}{4}$	290	1,220	254	130	660	2,554	6,300	8,854	120	100	12,000	82.5 p.c.	57.5 p.c.

The following tests which have been made of these machines are interesting, as showing the proportion which exists between the various losses occurring in a steam dynamo of this class, and which is to be noted, that although the efficiencies given are exceedingly good results, the engines and dynamos were perfectly new at the time of the tests, which were made for the makers own information, and not originally with a view to publication.

The electrical data are as follows :—

Volts, 120 ; ampères, 375 ; watts, 45,000 ; speed, 440 ; armature resistance, .013 ohms ; resistance of field magnet coils, 21.4 ohms.

Indicator tests of Goolden-Willans combination :—

1. The engine was run, with the armature disconnected, and found to absorb 8.43 I.H.P. when running light at 430 revolutions.

the efficiency of the steam dynamo can be given for any load, and the commercial efficiency of the dynamo calculated for any output.

The table below shows the calculations tabulated, it being noted that the loss in the shaft friction has been taken at .39 I.H.P. (this value was found to represent an average in later tests, the above value being exceptional, owing to the circumstances mentioned, but the individual test being for a difference, this was unimportant).

These calculations accord well with direct indicator

\* The loss in the core is probably considerably augmented by the fact that this dynamo was originally intended for 105 volts, but the field excitation was raised to give 125 volts at the original speed, the induction being thus increased, the leakage through the shaft and spider has been increased, thus causing eddy currents and loss.

tests. The dynamo giving 43,400 watts, the efficiency as indicated was 80·4 per cent., and, when giving 26,500 watts, the efficiency was 72 per cent.

Independent tests of these dynamos and engines at the stations, supplying current to the Houses of Parliament, have been since made by Prof. A. Kennedy, consulting engineer to the Westminster Electric Corporation, giving even better results than the above. The commercial efficiency in some reached as high as 85 per cent. and 86 per cent. ; but as further tests are being carried out on the same machines, the results are not yet complete.

THE NOMINAL LUMINOUS POWER OF CONTINUOUS CURRENT ARC LAMPS.

WE have long protested, writes the editor of *L'Electricien*, against the use of unsuitable or inaccurate terms, and vague designations which are only kept in use by custom and prejudice. By dint of repeating our assertions we may perhaps succeed in getting the matter taken up by others who are not the slaves of custom ; we shall therefore not fail to call attention to abuses of this kind whenever an occasion presents itself. We will, therefore, now discuss the (in our opinion) deplorable custom of characterising arc lamps by their more or less nominal photometric power.

In order to show how meaningless such designations are, we have drawn up a table from the books, catalogues and prospectuses of the chief industrial celebrities of both worlds, placing opposite each intensity of current feeding a given arc lamp, its corresponding nominal photometric power. In order to facilitate comparison we have reduced all the intensities expressed in carcel burners to decimal candles, considering the carcel burner to be equivalent to 10 decimal candles, although really, according to M. Violle, 20 decimal candles = 2·08 carcel burners ; there is, consequently, a difference of 4 per cent. between the decimal candle and the tenth of a carcel burner, but our estimate will be sufficiently accurate for our purpose.

Table of Nominal Intensities of Arc Lamps according to the constructors.

Intensity of current Amperes.	Sautter-Lemonnier	H. Fontaine.	Cance (under a globe).	Schuckert.	Crompton.	Latimer-Clark.	Ball.	John Davis.	Antwerp experts (1889).	M. Tischendorfer's Formula.

(B.D.—(decimal candle). N.K.—German normal candle.  
C.—English candle.)

The figures in this table show that a constructor, describing his machine as producing so many arc

lamps of so many candles each, gives it a designation which may perhaps facilitate its sale, but which is practically meaningless, since, with a given current, the quality of the carbons, the distance between them, their diameter, &c., may cause the luminous intensity to vary considerably, its value being in some cases even more than doubled. And we must not lose sight of the fact that in arc lamps mounted in derivation, the available potential at the terminals of the lamp being from 43 to 45 volts, some installations work at 80 effective volts, others at 75, 70 or 65, the difference being absorbed at an utter loss in a rheostat.

The same objections may be raised to the mode of designating dynamos and transformers by the number of incandescence lamps that they can feed. Some constructors mean lamps of 30 watts, others lamps of 40, 50, 56 or 60 watts.

A dynamo or transformer should never be designated in any other way than according to the number of available watts it can produce at a maximum normal charge.

Lastly, as regards accumulators, the statement of the weight of the plates conveys no meaning to us. We should like to see accumulators designated according to their maximum normal output, in ampères or in watts, and according to their effective capabilities in ampère-hours or watt-hours, for these are the principal essentials, which together with their price and duration, enable us to calculate quickly the number and the coupling of accumulators required for a given installation, much more accurately than the weight of the plates.

THE ELECTRIC LIGHTING OF DRESDEN.

[FROM A CORRESPONDENT.]

WHAT is thought in municipal circles in Dresden on the present position of electric lighting is curiously illustrated by a report in the *Teplitz Zeitung*.

On October 16th, this year, there was held a session of the Town Councillors of Dresden, the first item in the order of the day being to receive the report of the Chief Mayor, Dr. Stübel, on the preliminaries for the municipal electric works as proposed for Dresden. It is known that after various explanations and negotiations with Siemens and Halske, of Berlin, and the German Edison Company of the same city, who had both submitted calculated projects, it was resolved by the Dresden Town Council, on May 1st, 1887, that electric works should be erected at the cost of the city, to which resolution the municipal delegates gave in their adhesion on May 26th of the same year.

A mixed committee for this affair was then formed, and projects were submitted by Siemens and Halske, Kummer and Co., and Schuckert and Co. The German Edison Company had withdrawn its proposals. In the report of the Mayor-in-Chief, Dr. Stübel laid before the above municipal session the erection of a municipal electric works for a maximum connection of 25,000 glow lamps, and an outlay of 2½ million marks was recommended. The number of the gas flames installed in Dresden consists of 6,300 street lamps and 175,000 private lights. Consequently the proportion between electric light and gas expected by the Dresden authorities was 1 : 7.

At the meeting of representatives on October 16th, 1890, Dr. Blochwitz acted as reporter of the committee, which proposed that, "The committee decline the proposals of the Town Council, and hesitate at present to undertake the erection of municipal electric work, and prefer to await the results of the electric exhibition, to be held at Frankfort-on-the-Maine in 1891, and at the same time express the wish that in future, as in all extensive municipal undertakings, a competition should be invited, and that after the presentation of the projects a committee, consisting of at least three experts, should be formed for their examination."

In support of this motion, the reporter submitted that haste should be avoided; the affair was too serious, and millions of money might be sunk too rapidly. The charge was brought against Dresden that it came halting in the rear of all improvements; this was not here the case; there were not, so far, many electric stations, and a variety of experience will be obtained. The application of the accumulators recommended by Siemens is for the present merely an experiment. There are many more important things which should be done first—*e.g.*, the market halls, the exhibition hall, &c. He strongly urged that the proposal of the committee should be accepted. The town councillor Hartsig followed on the same side. He had, he said, informed himself practically on the electric lighting in Berlin. The frequent repairs which were there required in the cable from the Central, and other experiences, induced him to agree fully with the recommendation of the committee. He was of opinion that more experts should have been consulted. Above all, he regarded it as necessary to mention something which had not yet been openly brought forward, *i.e.*, the general public was of opinion that the electric lighting of the streets was involved in the erection of electric central works. This is an error, as nothing of the sort is, for the present, in contemplation. The public has therefore at present no immediate interest in the question. The loss and the interest on the say, three million marks required for the new works, must ultimately fall upon the community of the tax-payers. The entire installation was merely for people of distinction; for the little man (*anglice* for the poor man) there was here nothing. Lighting with the aid of accumulators was so young a child, that it might well be allowed to grow for a couple of years. There was no pressure; the electric lighting of business houses, offices, saloons, &c., is not absolutely necessary, like street cleansing, water supply, &c.

In Berlin he had heard nothing but lamentations from men of business compelled, by competition, to adopt the electric light, and troubled by the high price and the frequent repairs. He found the restaurants and cafés lighted electrically generally very dim, so that it was often scarcely possible to read the papers.

After some concluding remarks from Blochwitz, the reporter who said that the introduction of the electric light would not diminish the income of the gas company, the opinion of the committee was accepted by 47 votes against 17.

### THE BULL RING OF THE RUE PERGOLESE.

THIS enormous building, devoted to somewhat feeble imitations of Spanish bull fights, has been recently covered in, and in order to make use of the edifice at night, either for bull fighting or for concerts, lighting by electricity has been introduced.

The arena is circular, and has a diameter of 197 feet; the dome which covers this springs from iron columns 98 feet in height, surrounding the arena. From the ground to the centre of the dome is 190 feet. The exterior of the building is in shape a 30-sided polygon, described on a circle whose diameter is 328 feet. There is seating accommodation for 22,000 persons. Light ironwork supports the glass of the dome, the central portion of which can be bodily raised between 12 and 13 feet, so as to ventilate the building in summer. The movable portion of the dome has a diameter of 98 feet. At night, the principal source of light comes from just below the movable roof, that is to say, at a height of 197 feet. Here is a sunlight of the Patin type, and, in addition to this, a circle of 150 arc lights are arranged round the dome, the total lighting power being thus brought up to 30,000 candles. The two galleries are each provided with 60 Cance incandescence lamps of 32 candles, and the ground floor passages are lighted by 16 Cance in-

candescence lamps of 100 candles each, and 16 arc lamps, Patin type, of 8 ampères. The offices and dressing rooms are supplied with 200 incandescence lamps of 16 candles.

Especial attention has been paid to the arrangement, fitting, and construction of the engine, boiler, and dynamo rooms, with the result that they are in reality works of art, and will no doubt produce the effect of not only familiarising numbers with electric lighting, but also of increasing public confidence in this method of illumination, and of extending its application.

There are three Collet boilers, each supplying 3,300 lbs. of steam per hour. One of these boilers is kept in reserve, while the other two feed a Powell engine of 300 H.P., and a compound Chaligny engine of 100 H.P.

The alternating current is produced by a Ferranti dynamo of 3,000 lamps, and 4 Gramme machines of 200 lamps at 8 ampères.

There is also a battery of accumulators for feeding the relief lamps in case of accident to the main lighting.

### REVIEWS.

*The Year Book of Commerce.* Compiled under the authority of the London Chamber of Commerce, and edited by KENRIC B. MURRAY. London: Cassell and Co.

This is the second of the series of yearly volumes, prepared specially for business men, by the London Chamber of Commerce, with the object of showing the movement of the foreign trade and general economic position of the leading countries of the world. The volume, as compared with the former issue, gives additional statistics on a variety of topics of considerable value. In tables, now printed for the first time, information is given as to British trade with European countries under commercial treaties, with the increase of their population, and trade movements in 1888 as compared with 1860, international telegraph statistics, the progress of British trade since 1855, with quinquennial averages, rates of wages, trade of some of the South American States, China and Japan, and several others. With reference to the first-named table, the editor remarks that it affords most appropriate food for thought at the present moment. "This gives at a glance population and trade statistics of 17 European countries or states, in addition to the United Kingdom, with a record of the date of coming into force of the respective commercial treaties of Great Britain with them. Upon the total statistics the increases per cent. of population, of total imports and exports, of imports into the United Kingdom from, and exports from the United Kingdom to, the various countries are, as far as obtainable, stated in each instance. The illustration thus afforded is one which every business man can appreciate, and which points its own moral. At this juncture it has exceptional importance. The Continent of Europe seems destined, in 1892, to be involved in a rearrangement of its Customs tariffs of a wholesale nature. What France is inclined to do in that year, when all her principal commercial treaties expire, has been made very evident, and there, at any rate, there is little hope of a relaxation of the State-imposed barriers to commercial intercourse. Following in the train of the French treaties, most of the European States will be obliged to reconsider their position. It is therefore worthy of being noted that as far as British commerce with Russia, Sweden, Norway, Denmark, Holland, Belgium, Germany, Switzerland, and Austria-Hungary is concerned, it is regulated by treaties terminable upon a year's notice, which may thus be given early next year to expire in 1892. The British commercial treaty with Roumania terminates in July next; the treaties with France and Italy on February 1st, 1892; and those

with Spain, Portugal, Montenegro and Bulgaria at various dates in 1892. Consequently the position is one which cannot be ignored, and that it is realised by Her Majesty's Government is shown by the appointment of a Special Consultative Committee, in connection with the Board of Trade, to 'consider the approaching expiration of various commercial treaties, the probable effects upon British trade of such expirations, and the arrangements which may or should be made in lieu of those treaties.'"

*Magnetism and Electricity: A Class Book for the Elementary Stage of the Science and Art Department.* By J. SPENCER, B.Sc., Head Master, Science Department, Bradford Technical College. London: Percival & Co., King Street, Covent Garden.

The method adopted in this book of arranging the whole of the matter in a series of experiments has much to recommend it, as it appeals very forcibly to the student, but beyond this point there is but little to call for notice in the work, as it has no marked superiority over other excellent treatises which exist. The general arrangement of the matter is satisfactory, the illustration clear and fairly good, though, as is usual with teachers who have had no, or little, practical experience, descriptions of practical applications are exceedingly absurd; witness the description and illustration of an electric telegraph on page 135. Although we cannot highly praise the book for being written "to supply a want," we can at least say that those who purchase the same for the purpose of learning about electricity and magnetism will, if they carefully go through the whole course of experiments, obtain very thorough instruction in the elements of the subjects.

#### *Sound, Light and Heat.*

This book, by the same author and publisher as the foregoing, is a companion to the above, and does not call for any special remark. It is undoubtedly a handy volume.

*Practical Inorganic Chemistry. Elementary Stage.* By E. J. COX, F.C.S., Head Master of the Technical Science School, Birmingham. London: Percival & Co., King Street, Covent Garden.

This class-book is intended for the use of students preparing for the examinations of the Science and Art Department in the elementary stage of Practical Inorganic Chemistry. The whole arrangement of the book is exceedingly simple and thoroughly practical. The diagrams, which conclude the work, are very clearly drawn.

*Elementary Manual of Magnetism and Electricity. Specially arranged for the use of First-Year Science and Art and other Electrical Students.* By ANDREW JAMIESON. London: Charles Griffin and Co., Exeter Street, Strand.

This volume is a republication of the three manuals on "Magnetism," "Voltaic Electricity," and "Electrostatics," which we have noticed in a previous review; to the latter we have nothing to add, except to say that the complete volume forms an excellent elementary treatise on the subjects of electricity and magnetism, very practical in its arrangement, and possessing sufficient points of novelty to justify its publication.

#### THE WALKER AMMETER AND VOLTMETER.

ALTHOUGH there is at present a very large number of measuring instruments for electric light stations upon the market, embodying in their construction a great variety of principles, the one which is herewith described is somewhat different from most heretofore brought into use. There can be no doubt, says the *New York Electrical World*, that there is great need of a cheap and accurate instrument which is

easily calibrated, and the scale divisions of which are of equal length. An instrument which would seem to fulfil these conditions is illustrated upon this page. It is the invention of Mr. G. W. Walker, of this city, and in its construction he has made use of the principle which he has already utilised in his recording meter, described and illustrated some months ago in our columns. In its design Mr. Walker has endeavoured to provide a meter containing the fewest possible number of parts, and these of the simplest character consistent with accuracy and durability, and at the same time to reduce the cost of construction to so low a figure that the instrument could be placed upon many circuits which are now unprovided with meters, because of the large expense necessary in securing a satisfactory one.

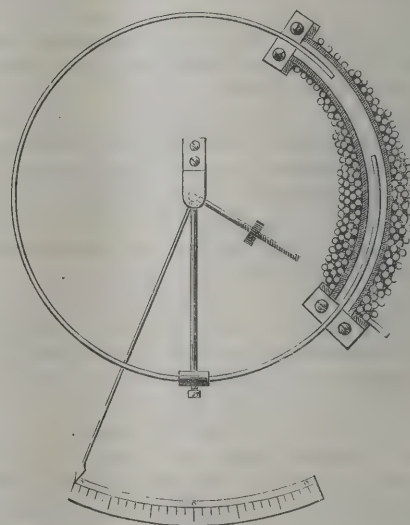

FIG. 1.

Fig. 1 shows very clearly the construction of the meter and all of its parts. A solenoid magnet of arc shape is secured in position against a suitable support by means of screws. A circular core of iron, somewhat hardened, and extending over about 270 degrees

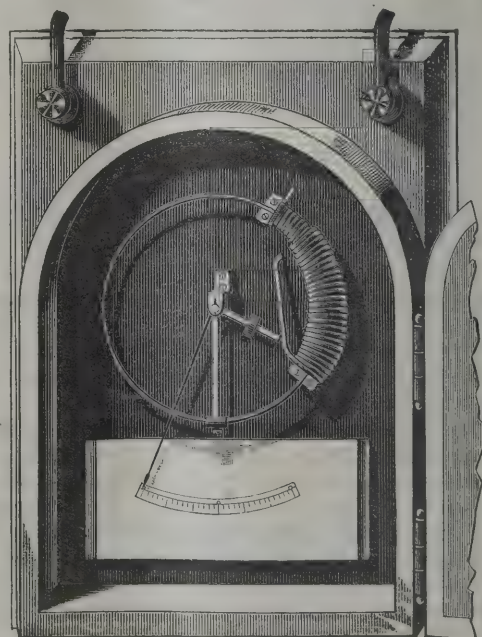

FIG. 2.

of circumference, is carried upon a bar, which is pivoted at the centre of the instrument, and swings in jewelled bearings. The needle or pointer of the instrument is also carried upon this same axis, and extends outward beyond the core to the reading scale, as shown in the figure. An arm which is threaded to receive a nut-like weight, as shown in the figure, is carried from the same centre, and by means of this the core may be balanced, so that when the instrument is not in circuit,

the pointer will stand at the zero of the scale. The solenoid is composed of a curved non-magnetic tube, and a helix of insulated wire wound upon the tube, which serves only as a support, so that it tapers or decreases in diameter from one end to the other, either gradually or by steps.

The core is made of comparatively hard iron, its free ends being joined by some non-magnetic material, such as brass, for the purpose of support, so that the core may be kept in a perfectly circular form. The ends of the core are arranged so as to stand within the coil when in a normal position. The upward end, however, may be made to stand without the coil, but within the field of repulsion of the magnet, the other end standing when in a normal position at a point about midway the length of a coil. By using a core of small diameter, it may be saturated by a slight percentage of the current used in the meter. The fact that the pointer moves over equal divisions on the scale for equal increments of current passed through the instrument, is attributed by Mr. Walker to the fact that the core, instead of being of soft iron, is somewhat hardened, and also to the fact that the coil which exerts the attractive and repellant influence upon the core is wound in the tapering manner described above.

Fig. 2 shows the instrument completed. The same construction, with the exception of the substitution of a fine wire of high resistance for the solenoid, makes the instrument a voltmeter instead of an ammeter, and both of these instruments are now made by the Walker Electric Company.

## POLARISING CONDITIONS IN A GALVANIC BATTERY.\*

By PROF. A. E. DOLBEAR.

WHEN hydrogen accumulates upon one of the plates of a galvanic battery so as to reduce the current, the cell is said to be polarised, and various methods have been devised to prevent this, some chemical, as in two fluid cells, and some physical, as when the plate is rotated, and these are called depolarisers; the idea being that the polarisation itself consists simply in the accumulation of gas upon the plate. I do not know that any attempt has been made to explain the underlying conditions present where chemical action is present or latent in a battery, which bring about such a result, for it is plain that such a result must have some antecedent physical conditions that determine it.

The following explanation has seemed to me to be probable, and the commendations of a number of my electrical friends induce me to publish it, not as proved, but as a step towards a clearer understanding of the mechanical conditions present in a galvanic battery.

When a piece of zinc is immersed in water it is found to be electrified, and its potential may be measured by a suitable electrometer.

Now, we know from purely chemical sources that there is chemism, or chemical attraction, existing between zinc and oxygen, and that under favourable conditions zinc will be oxidised. This so-called affinity of zinc and oxygen is not suddenly created by their juxtaposition under certain circumstances, but exists all the time, only waiting for an opportunity to show itself.

What then are the real conditions present when a piece of zinc is immersed in water? The zinc is a solid, the molecules cohere, and there is a certain degree of rigidity to the molecules. With the water it is different. As a fluid, the molecules are free to move about among each other with but little internal friction. As the molecule of water is made up of both oxygen and hydrogen, it may have an oxygen side and a hydrogen side, in which case, if there be any selective agency acting more upon the oxygen part of the molecule than upon its hydrogen part, and if the molecule as a whole

is capable of shifting its position easily by a simple rotation upon any axis, as is true in this case, then all the molecules of the water that come in contact with the zinc must be oriented by the zinc so that the oxygen side of the molecule faces the zinc at every point, and consequently the hydrogen side is away from it. This would be a true polarisation of the molecules of water, and the distance to which it would extend would depend upon the strength of the chemism between the two acting elements. Such a chemical field might extend indefinitely.

When a piece of carbon or copper or other element is placed in water, it exhibits similar electrical property, but different in degree from that of zinc; so similar polarisation of molecules would be set up about it. The difference in the degree of chemism between the two elements and the oxygen of the water would determine the rate of oxidation under given conditions, and this difference we call the electromotive force of the cell. Also, the mere fact that there was a difference in this particular between the two immersed elements would tend to produce between them a similar condition of arranged or polarised molecules.

All this might be expected to occur, whether there was a chemical reaction or not, that is to say, whether or not the zinc was dissolved and water decomposed. Whether this happens, or not, depends upon the degree of tension represented by the difference in the so-called chemism between the two elements, which difference we measure in volts, and needs to be about 1.5 for water.

If other solutions than water be used, the same mechanical conditions and arrangements would be present, differing from it only in degree.

The substance of the idea is this, that the chemism existing between the zinc and the element oxygen in the water *compels* the molecules of the water to turn so as to present their oxygen side to the zinc, which they are able to do freely, because such movements are not subject to appreciable friction in the liquid.

When the other battery element cannot combine with oxygen in any degree under the existing conditions, as when carbon or platinum is used, then only hydrogen will be set free, as there is a greater stress for the oxygen at the other element, and there must be an exchange of partners among the molecules along the whole line between the elements, according to Grothius's hypothesis; so that, underlying the accumulation of hydrogen called polarisation, is a real polarisation in which all the molecules are facing one way from the mechanical necessities present.

It seems not unlikely that this condition of things in a heating liquid might be observed by noting the effect produced by it upon a beam of light transmitted through the liquid, especially upon reversal of electrical condition.

## THE PROPOSED PACIFIC CABLE.

THE project of connecting Australia with Canada by a cable across the Pacific Ocean has now been before the public about 10 years, having been first suggested by Mr. Sandford Fleming in a report submitted to the Dominion Parliament in 1880. As a practical question, however, the history of the proposal may be said to date from 1887, when a conference of delegates from various parts of the British Empire was held in London. At this meeting the plan was fully explained by the delegates from Canada—Mr. Sandford Fleming and Sir Alexander Campbell—and aroused a great and for the most part a friendly interest. At the same meeting there was also revealed the fact that the project had a strong opponent in the Eastern and Eastern Extension companies, which now control the telegraphic communication between Australia and Great Britain, and enjoy a monopoly which would be destroyed if telegrams could be sent across the Atlantic, then through Canada, and then across the Pacific Ocean to Australasia. The conference adopted a resolution declaring "that the connection of Canada with Australasia by a direct submarine telegraph across the Pacific is a project of high importance to the empire, and every doubt as to its practicability should without delay be set at rest by a thorough and exhaustive survey." The favour with which the idea was received appears to have alarmed the existing companies, for last summer they endeavoured to make an

\* The Electrical Engineer.

arrangement which would have given their monopoly a new lease of life. They offered to reduce their cable rates one-half on condition that the Governments interested would give a guarantee equivalent to about £54,000 a year. The Australian colonies were willing to enter into this arrangement, but Great Britain and New Zealand declined to share in the guarantee, and there the matter stands to-day. In the meantime Mr. Sandford Fleming took the opportunity to explain the Pacific plan, and it will be convenient at this point to state the nature of the arguments which he used. It was contended by Mr. Fleming that the guarantee asked for in consideration of the reduction of the rates of the old company, namely, £54,000 a year, would be equal to the annual charge upon the capital required for the construction of a cable from Canada to Australia. The length of the cable necessary to stretch across the Pacific from Canada to New Zealand and Australia is estimated by competent authorities at 8,900 miles, and Mr. Fleming says that the outside cost of a cable of the very best type would be £1,800,000. Three per cent. upon this sum would amount to £54,000 a year. It is further pointed out that the building of the Canadian line would reduce the cost of messages from England to Australia to one-fourth what they are now, while the proposal of the existing companies is to reduce them by only one-half. The length of the line is not so formidable an obstacle to the success of the project as may at first sight appear; for owing to the presence of a number of stations in the Pacific, the longest stretch would be about 2,700 miles, the others ranging from 1,200 miles upwards.

So far as we can judge, the Australian colonies and Great Britain would stand to gain by the construction of a line which would destroy the monopoly of the old companies, effect a great reduction in rates, and give them a telegraph route lying entirely in the Atlantic and Pacific Oceans and in Canada, and therefore much less liable to be interrupted by an enemy than a route following the old lines of commerce. Canadians, of course, would take a friendly interest in a project which would benefit our sister colonies and Great Britain, and the question of Canada assuming any, and if so what, share of the expense of the scheme may safely be left for future consideration. It will be seen at once that her direct interest in the matter is not so great as that of Australia and England, the volume of business between those two countries being vastly greater than the volume of business between Canada and Australia. It is to be presumed that the promoters of the plan recognise this fact and would expect Canada to bear a corresponding small share of the expense. It is quite possible that in the future new conditions may arise which will greatly enhance the importance of the project from a Canadian standpoint. Her commerce upon the Pacific, now in its infancy, may grow to large proportions, especially if the statesmen of the future age are wise enough to adopt a policy which will promote instead of hindering the growth of commerce. In such a case the construction of a cable across the Pacific would be a matter not merely of importance but of necessity. From the imperial standpoint the importance of having a line from England to her Eastern possessions, laid wholly in the open seas and in countries under the British flag, would undoubtedly be of great importance; and to this aspect of the case British statesmen will no doubt give due consideration. —Globe, Toronto.

ELECTRICAL TRADES SECTION.

A MEETING of the section was held at Botolph House on Monday last, Mr. R. E. Crompton in the chair.

THE BOARD OF TRADE RULES.

The Chairman said, in reference to this matter, it had been left to him to prepare a formal document and submit it to the Council of the Electrical Engineers. He had been unable to carry out these instructions as no meeting of this body had taken place; however, he met the chairman and the secretary, but the result was not satisfactory, in so much as the president said he preferred that the initiatory action should be taken by the Electrical Section, who might submit to the engineers and the Board of Trade a formal letter stating that the rules were anomalous and a hindrance to the industry. Considerable energy had been spent by Mr. Wharton, Mr. Sellon, Mr. Gray and himself in having the conditions altered; they had privately sent to the Board of Trade two memorials, and he considered if one on the top of these came from the section it would probably move them in the matter. The situation was extremely critical; his firm, Messrs. Wharton and the Brush Company, had at the present moment installations running, the overhead wires of which were not in accordance with the Board of Trade rules, and it was impossible to make them so. They took objection to two rules, one of which said that every wire, whatever its thickness, should have a rubber or material to the thickness of one-tenth of an inch outside the copper, outside that there should be the usual protection of braiding. The Silvertown people informed him that if this rule were enforced, a wire to carry the smallest high pressure current for town lighting or transmitting power, would cost £70 to £80 per mile. The wire which was guaranteed by the Silvertown engineers cost £28 per mile, such a monetary burden therefore, would in most cases prohibit electric lighting. Another objectionable rule was that which laid down that it was absolutely necessary in all cases to use suspenders. This, again, would further increase the cost, and under those circumstances there could be little extension

of electric lighting. He spoke as one who knew, as he had 39 miles of conductors in Chelmsford which were put up before these rules were made. It seemed as if Major Cardew wanted safety at any price, no matter whether it prohibits electricity or not. In reply to Major Flood Page as to whether there was additional safety in these rules, he said it was quite the contrary, for when a wire was covered with a thick coating, it was difficult to centralise, there was more liability of the insulation being cut, and it was more liable to tear. The Silvertown company had paid special attention to this subject and it was claimed that their wire was perfectly safe; even Major Cardew admitted this, but when he got back to the Board of Trade office he made rules which are quite different. He considered the whole system of the Board of Trade unsatisfactory. The committee of the Electrical Engineers, who were responsible for the rules, were not practical men, and he held that they could not therefore draw up suitable rules.

After further discussion it was decided that Mr. Crompton should wait upon the Council of the Chamber of Commerce to see if pressure could be brought to bear on the officials of the Board of Trade, in the event of this not having effect, questions will be asked in the House of Commons.

THE QUESTION OF CORRESPONDENT.

Mr. Garcke said he and Major Flood Page undertook to bring forward a scheme dealing with this question. After referring to the loss sustained through the resignation of Mr. Trotter, it had struck them some new arrangement might be made, and it was that the chairman and the two vice-chairman should constitute themselves a kind of working committee, and if the Chamber of Commerce provided them with a junior clerk, pressing matters would receive efficient attention. It would practically resolve itself into an executive committee who would meet at intervals and report to the committee of the section the work done between the meetings.

INTERCHANGE OF INFORMATION.

Mr. Crompton had prepared a circular letter and tables which it was proposed to send to those who became members, for the purpose of supplying information as to cost of maintenance of stations and working expenses. This scheme was referred to by us in a recent number.

It was decided that copies of the tables should be sent to all members of the section for suggestions.

After Mr. Murray had referred to the expiration of many of the tariffs in 1892, the meeting terminated.

ELECTRIC LIGHTING IN PARIS.

WE take the following statistics as to the progress of electric lighting in Paris between the years 1885 and 1889, from the *Lumière Electrique*; the figures given refer to electric lighting by the municipality:—

Year.	Number of lights.	Systems.	Employed.	Number of fires caused by electricity.
1885	68	14 Lontin ... 12 Jablochhoff ... 40 Brush ... 2 Siemens ...	Place du Carrousel ... Parc Monceau. Parc des Buttes-Chaumont. Champ-de-Mars.	1
1886	66	14 Lontin ... 12 Jablochhoff ... 40 Brush ...	Place du Carrousel ... Parc Monceau. Parc des Buttes-Chaumont.	4
1887	63	14 Lontin ... 12 Jablochhoff ... 37 Brush ...	Place du Carrousel ... Parc Monceau. Parc des Buttes-Chaumont.	2
1888	65	14 Lontin ... 12 Jablochhoff ... 39 Brush ...	Place du Carrousel ... Parc Monceau. Parc des Buttes-Chaumont.	3
1889	393	14 Edison ... 40 Popp ... 37 Edison ... 27 Marcel Deprez	Place du Carrousel ... Boulevards, Concorde to Opera. Place de l'Opera to the Porte Saint-Denis. Porte Saint-Denis to the Place de la République.	33
		6 P ... 12 Jablochhoff ... 47 Brush ... 186 Various ... 24 " ... 35 Edison ... 16 P ... 4000 P ... 1300 ... 509 ... 287 ...	Place Clichy. Parc Monceau. Parc des Buttes-Chaumont. Halles Centrales. Halles Centrales. Galleries of the Palais-Royal and the Theatre Français. Parc des Buttes-Chaumont. Reception rooms of the Hotel de Ville. Council, board rooms, and offices of the Hotel de Ville. Basements of the Halles Centrales. Private service.	

NOTES.

**Lighting of the Ménagère.**—An important electric light installation has just been completed in Paris at the well-known warehouses and shops of La Ménagère. The current is supplied from the station of the Parisian Power and Electric Lighting Company, situated in the Rue des Filles-Dieu, and the installation has been put up by the Electric Lighting and Apparatus Company. It comprises 110 Cance arc lamps of 8 ampères, arranged two in series, and 161 incandescent lamps of 16 candle-power. Of the arc lamps, 20 are installed in the basement, 47 on the ground floor, 22 on the first floor, 15 on the second floor, and the remaining 6 in the annexe, balcony, and a side street. The incandescent lamps are similarly distributed throughout the buildings. Each series of two arc lamps is fed from a separate circuit, having an E.M.F. of 110 volts at the switch-board, whilst the glow lamps receive current from four main circuits at 110 volts. There are two distributing switchboards arranged in the basement, one being for the arc and the other for the incandescent lamps. The main brought in from the street is divided into two cables for each pole, passing through a meter to the distributing boards. Between the meter and the main is arranged a double pole switch, so that the current may be switched on to the boards or disconnected from them, as desired. The arc switchboard is fitted with suitable cut-outs, rheostats, switches, meters, &c., whilst on the glow-lamp board there are only four main switches and four main cut-outs. The arrangement of a circuit for every two arc lamps permits of any two being extinguished, as may be desired, though this method is not so satisfactory as multiple arc distribution.

**The Electric Light in Belgium.**—The Belgian town of Ninove, situated about 15 miles to the westward of Brussels, is the first in that country to adopt the electric light. The concession granted to the gas company, and, by-the-way, Ninove was the first town in Belgium lighted by gas, expired on the 30th of September last, and the municipality, having decided to abandon the employment of gas, has entered into a contract for 30 years with an electric lighting company of Brussels. The lighting is to include streets, squares, and public places, as well as the supply of electric light to private dwellings. The installation comprises two large boilers, two Ridder engines of 20 H.P. each, two Siemens dynamos of 16,000 watts, and two batteries of Tudor accumulators capable of feeding 600 lamps for six hours. The distribution is effected by means of overhead wires. These are bare, of bronze, and 3·5 mm. diameter. They are carried on porcelain insulators supported by iron brackets. The public lighting consists of 120 lamps of 25 candles, mounted on the old gas lamps. For private lighting, the electric current will be supplied at 9 centimes per 100 watt-hours at a tension of 110 volts. The cost will be rather less than that of gas, which has lately been charged at Ninove at the rate of 18 centimes per cubic metre.

**The Electric Light at Chagford.**—A woollen factory, which has been unoccupied for some years, in this picturesque Dartmoor village, has been leased by Mr. G. H. Reed, millwright and machinist, who intends to utilise the water-power and wheel in his business, and hopes to supply the electric light to the inhabitants, using the water-wheel to work the dynamo. He gave an experimental installation last week, using Joel's shunt-wound dynamo, 100 volts 30 ampères, giving 40 16-C.P. Edison-Swan lamps. The brilliant, soft light was highly appreciated by the visitors, contrasting, as it did, most favourably with the gas supplied at Chagford. An electric lighting company is being formed, and it is expected that ere long Chagford will have a permanent installation.

**City and Guilds of London Technological Institute.**  
—The report of this institute for 1890 shows the following results of the examinations as regards the electrical subjects :—

° Taught in classes receiving grants on the results of the examination.  
† "External Candidates" taught in other institutions, or prepared by private study.

It will be seen that a very large increase in the number of "Electric Lighting" candidates has taken place.

**The Electrical Trades Union.**—Mr. J. Burns, L.C.C., addressed a meeting at the Bricklayers' Hall, Southwark Bridge Road, last Saturday night, held with a view to inducing non-members to join the Electrical Trades Union. He said he regretted that a Union had not been formed before, because instead of prices and wages being increased, they had, in some cases, been reduced, and boy, girl, and women labour had been introduced. The electrical trade was still in its infancy, and the business must extend. Electric lifts, motors, trains, and other methods of transmitting power would soon be adopted, and Vestries and Town and County Councils would, ere long, undertake public lighting. With the inception of electric lighting, he hoped the men who were engaged in the electrical trade would do everything in their power to help men like himself, who were members of public bodies, and who were determined to see that in any scheme of the kind Trades Union clauses were agreed to. It was a splendid opportunity for them to do something for themselves. They could fix the rates of wages, the hours of work, and the conditions of labour under any standard they thought fair and right if they had the courage. They had a splendid future before them; but if they did not take advantage of the opportunity, they deserved to remain in the condition they now were. Mr. Burns also pointed out to his hearers the advantages of Trades Unionism, and a resolution in support of the Electrical Trades Union was then proposed by Mr. A. J. Walker, and carried unanimously.

**Siemens & Halske.**—The taking over of the electrical works at Vienna, belonging to the Berlin firm of Siemens & Halske, as well as the Buda-Pest electric railway, to which we alluded last week, is now an accomplished fact. A limited company is to be formed by the Anglo Bank, Mr. Siemens becoming a managing director of the new company.

**A Cable Wanted in Paraguay.**—The Hon. F. J. Pakenham, British Minister to the Argentine Republic and Paraguay, says, "A want very largely felt at Asuncion is regular telegraphic communication with Monte Video or Buenos Ayres, and so with the world in general. At present (August, 1890), as in 1886, the telegraph line stops on the coast of the Argentine province of Corrientes, the missing link between which and the line in Paraguay being furnished by a person of apparently somewhat lethargic habit, whose movements on the Parana in a canoe seem rather to depend on the rule of *avoidsupois*, as applied to the bundle of telegrams whereof he is bearer, than to the urgency or value of the messages themselves. Doubtless, however, an improvement will be apparent in this direction ere long."

**Simple Pole Finder.**—In the New York *Electrical Engineer*, Mr. Arthur J. Newell publishes, as the result of some considerable experimenting, an account of a pole tester which he thinks will be of interest to many people. The invention consists in saturating litmus paper with sulphate of soda and drying. When the paper is to be used it is wetted, and on the application of the wires to be tested a red spot on a blue paper represents the positive pole; if a red paper is employed, then a blue spot will show the negative pole. Mr. Newell is probably unaware that a paper for pole-finding was brought out and placed on the market two or three years ago by Dr. Wilke, which paper has several advantages over the litmus preparation, its colour being white, finely contrasting with the rich crimson stain produced by the negative wire.

**Overhead and Track Wiring for Electric Railways.**—The superintendent of the Albany Railway, Mr. W. H. Cull, says that too much attention cannot be paid to overhead construction and track-wiring. The insulation of the hangers should be capable of eliminating moisture, and glass or mica has given most satisfaction. Insulation cannot be too good. The trolley wires should be divided in sections, for the greater facility in locating any fault, and, if possible, each section should have a separate feeder wire; a circuit switch at the generating station would enable the attendant to pick out the faulty section while still retaining the rest of the circuit in working order. Track wiring and ground connections are the most important factors in the operation of an electric road. The return wire should be of ample section, connected to each rail twice. All joints to be well soldered and wiped. The Albany Railway has, in addition to these arrangements, copper ground plates at intervals of 1,000 feet, and at a sufficient depth to insure their being in permanent moisture. The resistance thereby is so low that no leakage interferes with telephone circuits, neither is a metallic return requisite from the electric road to the power station more than a mile away.

**Halifax and Bermudas Cable Company.**—The daily journals announce that the Halifax and Bermudas Company's cable has been duly tested, and a certificate granted by the Government, who paid the first quarterly instalment last week, in terms of their agreement with the company.

**Tenders Wanted.**—For providing and fixing electric bells to firemen's houses at Pontypridd. Particulars of the secretary, Mr. E. W. Rees, Pontypridd.

**The Coefficient of Self-Induction.**—We observe that the "Henry" has been introduced into a scientific paper printed by an American contemporary as the title by which the coefficient of self-induction is to be known. Probably it will not be long before it will be disseminated throughout the scientific world as the accepted term for that coefficient.

**Price of Incandescent Lamps.**—In the home of free trade, England, the unfortunate monopoly in the manufacture of incandescent lamps keeps up the price of lamps to an almost prohibitive figure. In the United States, on the other hand, notwithstanding the great increase in the value of platinum, 16 C.P. lamps are selling at 44 cents each. The platinum wires now cost nearly three times what they did formerly, but in spite of this extra expense, competition compels, and the use of machinery enables, the manufacturers to quote low and still retain a profit. Red-hot hairpins should become things of the past. Brilliancy, and economy in consumption of power, will be esteemed more and more as the essential qualities of an incandescent lamp.

**Telephone between Paris and London.**—The French section of the telephone line and cable which is to connect London with Paris has been completed. It consists of two overhead bronze wires, parallel, and crossed at intervals to diminish the effects of inductive disturbance.

**Memorandum for French Elmore Shareholders.**—You paid the Foreign and Colonial Company £116,875 in cash and £66,500 in shares for the privilege of your company's existence. A few months afterwards you receive a circular from your directors, congratulating you on the fact that the Foreign and Colonial Company has arranged to hand you back £50,000 of the money you had paid them in order to add to your available working capital; you to pay equivalent to over  $7\frac{1}{2}$  per cent. per annum interest, and to issue debentures which presumably give the holders for £50,000 a first charge on what you have paid the same organisation £116,875 for (cash only), as well as a charge on any property your own further expenditure may create.

**A Chair of Industrial Electricity at the Paris Conservatoire of Arts and Sciences.**—The Minister of Commerce has just created, at the Conservatoire of Arts and Sciences, a chair of industrial electricity. The Academy of Sciences will be invited to present a list of candidates for the new chair.

**Electrical Fittings.**—One of our young, and therefore energetic firms of electrical engineers, Messrs. Arthur B. Gill & Co., of 4, Bombay Street, Bermondsey, S.E., writes to draw our attention to the extensive and convenient showrooms lately acquired by them at 36, Parliament Street, Westminster, S.W., for the exhibition and sale of their electrical manufactures and fittings—of everything, in short, connected with the uses of electrical energy. It is intended to keep a large stock of goods at these showrooms ready for immediate delivery, and special attention is desired, firstly, to a varied and comprehensive selection of artistic electric light fittings; secondly, to a stock of Henley's electric light wire and cables in all the leading types and sizes.

**North-East Coast Engineers.**—We have received the list of meetings of the North-East Coast Institution of Engineers and Shipbuilders. A good programme is promised, more of interest to shipbuilders than electrical engineers. Mr. W. C. Mountain reads a paper on "Electrical Engineering" on March 9th.

**Institution of Electrical Engineers.**—Among those who have accepted the invitation of the President and Council to the annual dinner on the 20th inst. are the Postmaster-General, the Attorney-General, the Presidents of the Royal Society, the Chemical Society, and the Institution of Mechanical Engineers, and the Vice-Presidents of the Institution of Civil Engineers, Sir Arthur Blackwood, the Astronomer Royal, and Dr. Coleman Sellers, one of the members of the International Niagara Commission. We understand that in anticipation of the large numbers who are expected to respond to the invitation of the President and Mrs. Hopkinson on the evening of the 19th inst., on the occasion of the President's *soirée*, the Prince's Hall has been engaged, in addition to the Galleries of the Royal Institute of Painters in Water Colours.

**Personal.**—Messrs. J. D. F. Andrews & Co. have purchased the goodwill and assets of the firm of Messrs. White, Romanze & Co., of Kingsbury Road, Dalston, and 3 and 4, Great Winchester Street, E.C., who have been carrying on a considerable business in the manufacture of arc lamps, switches, &c., and also telephones, type-printing instruments, and electric bells, besides having many important electric light contracts.

**Long Distance Telephony in Italy.**—A fortnight ago a series of experiments was conducted at the chief telegraphic office in Rome with a new telephone line between that town and Albano, a distance of 20 miles, or 40 in all, the circuit being metallic throughout. The trials were successful.

**Mr. Lee Baptý Arrested.**—Mr. Lee Baptý, the late manager of the Edinburgh Exhibition, was arrested at Waverley Station, Edinburgh, on Saturday night, as he was about to take his departure to the south. The arrest was made under a warrant, to prevent Mr. Baptý leaving the country until he had paid or found security for his contribution of £500 to the guarantee fund of the exhibition. Security was promptly found and he was released. Since then he has written an indignant letter to the *Standard*.

**The Asbestos-Faced Valve.**—We omitted to say that this article, described in our last number, will be placed on the market by the Bell's Asbestos Company, Limited.

**Honours for the Compound-Winding Advocate.**—Mr. Graham Murray, who so ably conducted the respondents' case in the compound winding, has been appointed Sheriff of Perthshire.

**Railway Stores Wanted.**—The Cheshire Lines Committee require a supply of telegraph instruments, wire, and materials. Patterns can be seen, and specifications with forms of tender obtained, upon application to Mr. S. S. Barton, Cheshire Lines, Warrington.

**Anglo-American Telegraph Company, Limited.**—This company has opened an office for the reception and delivery of telegrams at No. 2, Northumberland Avenue, Charing Cross, thus placing the West End of London in direct telegraphic communication with New York, Canada, and all other places in the United States, West Indies, &c.

**A New Professor.**—Mr. J. Swinburne has just been dubbed "Professor" Swinburne by the *Elektrotechnische Zeitschrift*. This gentleman has evidently risen in the estimation of Mr. F. Uppenborn, though he may perhaps not care much for the "promotion." Mr. Swinburne's American "professorship" is a matter of longer standing.

**The Bradford Free Library.**—The museum and three top landings of the staircase of this library are now provided with the electric light. The result has been eminently satisfactory, both as regards quantity and quality of the light produced. The installation consists exclusively of 16-candle incandescent lamps, which are equally distributed over the room by means of pendant wires. The installation was completed on December 23rd, 1889, and has been working without the slightest hitch ever since that date. It has been decided to light by electricity the whole of the premises.

**Underground Telephony in Germany.**—The results obtained with the underground telephone circuits in Berlin have been so satisfactory that the Imperial Post Office authorities are now making experiments with long-distance underground wires. There are already in operation a telephone cable between Berlin and Küstrin, a distance of 57 miles; and a line from Berlin to Hamburg, 60 miles being overhead and 25 miles underground, whilst shortly the latter will be extended to 186 miles in length. The results with these long-distance wires are said to be very favourable.

**A 200,000-watt Arc Lamp.**—In a recent issue of *La Lumière Electrique*, M. de Fonvielle, in describing the electric lighting of the Gran Plaza de Toros in Paris, to which we refer on another page, states that the arena is partly lighted "by a Patin arc lamp taking 400 ampères at 500 volts, giving 8,000 C.P., and absorbing 50 H.P." A representative of a contemporary has, however, failed to find this large lamp, and states that only Cance arc lamps are used to light the arena. He demands the confirmation of these extraordinary figures.

**Porcelain Fittings for Electric Lighting.**—Messrs. Taylor, Tunnicliff & Co., who are extensively engaged in the manufacture of porcelain fittings for the electric lighting trade, have recently completed special machinery for overcoming a trade difficulty, which will doubtless lead to very satisfactory results, and supply a want severely felt by electricians engaged in fitting up these goods with the necessary metal work. We refer to the tapping with a very fine thread the small holes in porcelain switches, cut-outs, ceiling roses, &c., thereby enabling manufacturers to fit these articles up with metal work without the objectionable metal nuts, &c., at the back of such fittings, which have hitherto been a fruitful source of mishaps.

**Notice of Removal.**—Messrs. Davey, Paxman & Co. inform us that they are removing their London offices to larger and more convenient premises, at 78, Queen Victoria Street, E.C.

**Accumulator Traction in Paris.**—The action taken about a year ago by the French Electrical Accumulator Company in putting into service several accumulator cars on the Levallois-Madeleine tramway in Paris has now been followed by the company for the electrical working of metals. This company is now exploiting a tramway between the Palais de l'Industrie and the Place de la Concorde by means of a storage battery car fitted with Laurent-Cely accumulators. A noteworthy feature is that the car runs upon a Decauville tramway of the 2-foot gauge. The car is mounted upon two axles, and carries two Hillairet motors of 6 H.P. each. Each motor drives, by means of gearing, one of the axles, the reduction in the speed being in the ratio of 10 to 1. The battery consists of 64 cells containing 11 plates. These cells are placed in eight boxes, and the total weight of the car, without passengers, is 4½ tons. By means of a suitable switch the cells can be put in series or in parallel. On starting the car the current discharge is 90 ampères, and in ordinary running the consumption is 45 ampères.

**The Woking Electric Supply Company.**—This company has commenced operations, and applications have been received for nearly 700 lights. The Electric Trust erected the station and supplied the plant, and the whole of the electrical arrangements were designed and carried out by Mr. J. Appleton, of Guildford and London. The provisional order enables the company to charge 10d. per Board of Trade unit for electric current, but the price has been fixed at only 8d., being equivalent to about 8s. per 1,000 feet of gas. The company has made provision for using the light from half an hour before sunset until midnight, but as soon as it finds that there is a demand for light at a late hour, it will be prepared to extend their time of running.

**The Pacific Cable.**—In a former issue we mentioned that Sir John Pender was reported to have announced his intention of visiting Hong Kong, next year, *via* Canada, and of interviewing, *en route*, Mr. Sandford Fleming. The following is an extract from his letter :—“ . . . travelling by the Canadian Pacific line, when I hope to inspect that wonderful undertaking in which you have played such a prominent part, and at the same time discuss with you the best means of establishing closer telegraphic communication between Canada and the Australian Colonies, when the time is ripe for carrying out the work.”

“If the various governments interested are determined to have a line across the Pacific, and are prepared to incur the requisite expenditure for the purpose, I am quite ready, as I have always told you, to co-operate in carrying out the work on fair and reasonable terms. In this way the object might be obtained more easily and economically than if third parties were employed.” There is a charming frankness and *naïveté* about this last remark which will no doubt commend itself to the “third parties”; and we would ask how long is it since certain persons have become converted to the belief that no insuperable physical difficulties stand in the way of laying a cable across the Pacific Ocean? Mr. Fleming, in his reply, is reported to have said that the means taken to establish the new telegraphic communication are entirely secondary, provided the new lines be secured.

**The Lane-Fox Patents.**—Some of our readers will be interested in an advertisement appearing in the centre of this paper, with regard to the subject of which we are given to understand that the only claim which the Lane-Fox Electrical Company has so far decided to enforce has been based on Mr. Lane-Fox's leading patent, No. 3,988\*\* of 1878. But this moderation was largely misunderstood, and attributed to different motives; and as the company also finds a disposition amongst certain members of the trade to evade the matter at issue rather than to meet it fairly, the Lane-Fox Company has now determined to anticipate such attempts by enforcing the claims based upon letters patent No. 4,626 of 1878, for the use in connection with its system of shunt “electro-meters,” that is to say, of the class of instruments commonly known as voltmeters or potential electro-meters, with or without automatic attachments. We may also call attention to a slip of the pen in Mr. Lane-Fox's last letter to us, by which it is dated October 4th, by mistake for November 4th. This might lead some of our readers to look in vain for an article in the issue immediately preceding that date (October 4th).

**Lighting the Guildhall.**—On the occasion of the Lord Mayor's banquet at the Guildhall on the evening of the 10th inst., the hall was illuminated by about 500 incandescence lamps artistically attached to the gaseliers above the tables, and the excellent effect produced was greatly admired. The installation was carried out by the Brush Electrical Engineering Company at very short notice, and the result reflected great credit on all concerned.

**Efficiency of Combined Engines and Dynamos.**—The following letter from Messrs. Sautter, Harlé and Co. appeared in the last issue of a valued French contemporary :—In *L'Electricien* of November 1st are published the results obtained in recent trials, made in England, of a system composed of an Edison-Hopkinson dynamo, worked directly by a Willans engine. The satisfactory results obtained are not surprising. In France renderings quite as high are obtained. The following figures, which may perhaps be of interest to your readers, have been arrived at under the supervision of naval engineers in trials of the systems of motors and dynamos, working directly, constructed by us in 1890 for lighting the ironclad *Neptune*. They may serve for purposes of comparison. The dynamos of the *Neptune* supply a current of 75 volts and 200 ampères, or 20 electrical H.P. at 350 revolutions per minute. The consumption of steam at a pressure of 6 kg. per cm<sup>2</sup>, instead of being 11.3 kg., is less than 11 kg. per electrical horse-power hour measured at the terminals of the dynamo. A direct trial by the Prony brake, on the motor, showed a consumption of 8.9 kg. of steam per *effective* horse-power hour, instead of 9.8 kg. per *indicated* horse-power. The consumption is therefore less than in the case quoted, and the difference will seem all the more worthy of mention when we consider that the system gives only 20 horse-power instead of 72, that the pressure of steam is 6 kg. per cm<sup>2</sup> instead of 8, and that the dynamo makes 350 revolutions per minute instead of 430.

**Telephone Working.**—Mr. J. J. Carty, of the Metropolitan Telephone and Telegraph Company, writes to us under date, November 1st, as follows :—My attention has been called to an editorial note in your issue of October 17th, referring to my remarks at the Detroit Telephone Convention, in which it is stated that I seemed to be unaware that the system of bridging bells invented by me has been in use for many years in the British Post Office telephone service, and that it is described in the *Telephone*, by Preece and Maier. I would call your attention to the fact that, as shown by the official report of the convention proceedings and all published accounts of my remarks, I did not claim any novelty for the bridging system *per se*, being well aware that it has been in use for years both in Europe and in America. My invention, however, relates to a specially designed bridging magneto bell, by means of which the talking and signalling on a line containing 20 stations equipped with this bell are equally as good as with a line containing only two stations. These results are not attainable with the ordinary form of magneto bell. The details of the construction of my bell were not described by me at the Convention, as an application for patent rights was then pending in the U.S. Patent Office. So far from their being any description of a bridging system employing magneto bells in the *Telephone*, it is expressly stated in that work that the magneto bell has not been adopted by the British Post Office for telephone work, and there is no mention in the book of any method of connecting a number of stations with magneto bells by bridging the instruments across the circuit. In justice to myself, I must request you to publish this letter in your next issue, as if your editorial statement as to the absence of novelty in my invention is allowed to pass uncorrected, it might unfavourably affect my interests in the matter of the disposal of the European rights to use the bridging magneto.

**The Popp Compressed Air System.**—A German contemporary waxes wroth because the commune of Rixsdorf, near Berlin, has, on the advice of an Imperial architect, resolved to introduce the Popp compressed air system for lighting and power purposes. The same journal, in referring to a circular issued from Lucerne inviting subscriptions to a proposed Popp central station in that town, asks what authorities have spoken favourably of the system.

**Civilian Electricians in War Time.**—In Lient. Bradley A. Fiske's paper, published in another column, the author argues that as the force comprised by the standing regular army and navy is so small, it would only serve as a nucleus around which the fighting forces could be formed. Since the applications of electricity have extended to so many branches of military and naval arts, and have, in fact, become absolute necessities, the supply of competent officers and men, insufficient as it is in time of peace, would prove utterly inadequate in case of war. Lient. Bradley enumerates the many and varied uses of electricity in navigation, gunnery, torpedo work, &c., and proceeds to point out where, in his opinion, the civilian could be best employed. He suggests that on board electrical torpedo launches and electrical picket boats, at fish-torpedo stations, in submarine mining both for harbour and coast defence, in addition to signalling work by telegraph or telephone, the civilian has his proper sphere. But, he adds, the civilian could also be advantageously employed on ships of war for the reason above stated—the insufficiency of a trained and competent regular staff. The author proposes that at all important ports there should be a corps of electrical engineers, drilled to some extent, and attached to and embodied with the national guard. The higher ranks would be instructed in navigation, gunnery, surveying, &c., while the lower would be taught the handling of apparatus.

**The Spanish-Morocco Cables.**—We understand that the contract for connecting Spain with her settlements on the coast of Morocco by submarine cables has been given to Messrs. Pirelli and Company, of Milan. It will be remembered that the original decree was withdrawn, and a new one issued, upon which the present contract has been made. Some of the conditions are slightly altered, the maximum price per mile of cable being now fixed at £160, payable in ten years by yearly instalments. The contractor during this period has to maintain the cable at his own cost. The sections between Almeria—Alboran and Alboran—Melilla must be laid and working within three months from date of signing contract; the other sections within six months. The lengths specified for each section differ slightly from what were given in the former decree. No stipulation is made as to quantity of each there should be laid, the decision on this point being left in the hands of the commission appointed by the Spanish Government.

**The Telephone in France.**—Twenty-eight towns in the departments of France have acquired, through their municipalities, a telephone service. In eight other towns the telephone lines are in construction, and will be completed in two months' time. Plans are being got out and surveys made for supplying 13 more towns with telephone systems. Of interurban systems there are only two actually working; there are seven in construction, and ten under consideration. Seven towns are connected with Paris by the telephone, and there are four more in course of being joined to the capital. In Algeria, the only two towns possessing the telephone are Algiers and Oran.

**The Late Electric Light Accident in Paris.**—At the last sitting of the Paris Municipal Council that body was engaged in considering the explosion following a fire in the cellars of the Grand Café. From some explanations given by the Secretary-General of the Prefecture of Police, though the enquiry is not finished, it appeared that the responsibility for the accident was due to the electric light company which occupied the underground portion of the premises. This company, the night before the accident, replaced the man who had formerly been in charge by an inexperienced man. The conclusion which the Council arrived at was as follows: The Prefecture of Police and the Prefecture of the Seine rejecting altogether the responsibility of

surveillance, the Council voted the following order of the day, proposed by M. C. Laurent: "Considering to what dangers the installation of the electric light in Paris may give rise to, this body expresses a wish that Parliament, by a special law, will assimilate the electrical industry with those which are looked upon as dangerous and subjected to the incessant surveillance of the Prefecture of Police."

**Electric Launch in Milan.**—The Franco-Italian Industrial Electrical Company, of Milan, is demonstrating the capabilities of an electric launch in the docks of the Porta Ticinese. The launch is 24 feet long by 5 feet wide, and will carry 12 passengers. It contains a battery of accumulators, and an Immisch motor of 1½ H.P., the speed of the launch being 8½ miles an hour.

**The Electro-Deposition of Copper.**—We have not yet had any further data on this subject from Mr. W. Stepney Rawson.

**Quick Cable Service.**—The following is taken from the Montreal *Daily Witness* of October 30th:—"One of our local magnates sent a cablegram to London *via* the Commercial cable this morning at 10.27, and at 10.40 he had a reply, just 13 minutes. In this time the message was sent from Montreal to Canso, thence to Ireland, where it was reported to London. A transaction was effected on the London Stock Exchange, the reply written and came travelling back again, reaching the sender in 13 minutes. The gentleman could scarcely credit it, but on examination of his sent message and his reply thereto found the facts to be as above."

**The New Thomson Alternating Meter.**—Recognising the value of a simple and reliable device for measuring current, Prof. Elihu Thomson has in the past devoted not a little attention to the design of various meters, among which probably those of the oscillating type, in which a volatile liquid is employed as the moving force, as it were, are best known. Recently, however, says an American exchange, Prof. Thomson has devoted particular attention to the construction of a meter which shall be adapted to both continuous and alternating currents and at the same time indicate not only the consumption of current, but give it in the value of the pressure on the mains; in other words, a power or wattmeter. The manner in which Prof. Thomson has worked out this problem is highly ingenious and is apparently based on simple principles. The problem to be solved evidently was to construct a motor in which both the pressure and the current should be the factors determining the speed and a device embodying a retarding force which should vary in the direct ratio with the speed of the machine. The relative disposition of field and armature of the motor and their connection with the working circuits fulfils the former conditions, while the disposition of the copper disc retarded by the encircling magnets fulfils the second. With constancy of magnetism assured in the permanent magnets and friction reduced to a minimum, as it appears to be in this instrument, its accuracy ought to be very high. Not the least interesting point in connection with it is the quality it possesses, as exhibited by the curve, of affording practically uniform readings for both continuous and alternating currents. We hope to illustrate this apparatus in our next issue.

**New Study in Natural History.**—In a letter to the New York *Electrical Engineer*, "Professor" J. Swinburne says:—"We are sending the Westinghouse Company a 50 lighter (transformer) to test. In a few weeks the Westinghouse advertisement will read, 'It will pay you to throw away our converters and substitute the Hedgehog make.'" This animal is an amusing little cuss.

**The New Electric Railway.**—It is stated that the new City and South London Electric Railway, which was formally inaugurated by the Prince of Wales a few days ago, will be opened to the public on the 26th inst. Let us hope, however, that no premature start will be made. Better wait several weeks longer if any uncertainty exists, for any little hitch, which can readily be overlooked on an inauguration day, will not, if allowed to occur in actual working, meet with the same sympathetic feeling from the travelling public.

**Electric Lighting in Germany.**—According to statistics there were 21 central electric lighting stations in Germany in the year 1889. The horse-power employed is given as follows; Barmen, 600; Berlin, 10,000; Brunswick, 2,000; Bremen, 600; Breslau, 500; Cologne, 500; Darmstadt, 450; Dresden, 500; Eberstadt, 100; Elberfeld, 325; Ems, 100; Frankfort, 1,000; Gærlitz, 450; Halle, 550; Hamburg, 1,200; Königsberg, 300; Zubeck, 300; Magdeburg, 500; Mulhausen, 300; Olmütz, 300; Strasburg, 400; the total amounting to 20,975 H.P.

### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**International Okonite Company, Limited.**—The statutory return of this company, made up to the 23rd ult., was filed on the 30th ult. The nominal capital is £340,000, divided into 11,334 ordinary, 11,334 preference, and 11,332 vendors' shares of £10 each, the latter being considered fully paid up. Upon the ordinary and preference shares £7 per share has been called up, the calls paid amounting to £147,187 17s. 6d., and unpaid to £11,488 2s. 6d.

**S. Z. de Ferranti, Limited.**—An agreement of 30th June, filed 25th ult., provides for the purchase by the company of the business of S. Z. de Ferranti, carried on at Charterhouse Square, at Deptford, and at St. Benet Chambers, Fenchurch Street. The purchase consideration is £99,930, payable as to £19,930 in fully paid preference shares, and £80,000 in fully paid ordinary shares.

**Stamford Hill, Tottenham, and Edmonton Electric Light and Power Supply Company, Limited.**—The name of this company has been changed to the West Metropolitan Electric Light and Power Company, Limited, in accordance with a special resolution passed at a meeting of the members held on the 21st ult., and confirmed at a meeting held on the 5th inst.

**Woodhouse and Rawson United, Limited.**—The annual return of this company, made up to the 24th ult., was filed on the 6th inst. The nominal capital is £350,000, divided into 40,000 ordinary and 30,000 preference shares of £5 each, the whole of which are taken up; 8,564 ordinary and 9,936 preference shares are considered as fully paid up. Upon 31,436 ordinary shares £2 10s. per share has been called up, and upon 20,064 the full amount has been called. The calls paid (including £85 paid in advance, amount to £178,826 10s., and unpaid to £180. Three ordinary and 20 preference shares, upon which £11 10s. has been paid, have been forfeited.

**Crossley Telephone Company, Limited.**—The annual return of this company, made up to the 25th ult., was filed on the 5th inst. The nominal capital is £100,000, divided into 5,000 "A," 12,500 "B," and 2,500 "C" shares of £5 each. The shares taken up are 607 "A," 120 "B," and 350 "C," all being fully paid up.

**Taunton Electric Lighting Company, Limited.**—An agreement of 28th ult. (filed 6th inst.), cites that the Laing, Wharton, Down Construction Syndicate is now supplying to the company, certain plant and machinery for the company's new dépôt at Taunton and for other works connected with the company's lighting operations at Taunton, the total cost of the same being £1,230. It has been arranged that one-half the amount shall be paid in fully paid shares of the company, and accordingly, under this agreement, 123 fully paid shares of £5 each will be allotted to the syndicate.

**Laing, Wharton and Down Construction Syndicate, Limited.**—The annual return of this company, made up to the 1st August, was filed August 15th. The nominal capital is £40,000, in £100 shares. 399 shares are taken, 133 of which are considered as fully paid up. Upon 266 shares the full amount has been called and paid.

**Allan Everett & Sons, Limited** (metal manufacturers, electrical engineers, &c.).—The statutory return of this company, made up to the 16th ult., was filed on the 21st ult. The nominal capital is £300,000 divided into 20,000 ordinary and 10,000 preference shares of £10 each. The shares taken up are 12,000 ordinary and 10,000 preference; 4,000 of the former and 3,300 of the latter are credited as paid up to the extent of £32,000 and £33,000 respectively. Upon 8,000 ordinary shares £8 per share has been called, and upon 6,700 shares the full amount has been called. The calls paid amount to £131,000. Registered office, Adderley Street, Birmingham.

### CITY NOTES, REPORTS, MEETINGS, &c.

#### The Western and Brazilian Telegraph Company, Limited.

THE report of the directors presented at the twentieth ordinary general meeting of the company yesterday states that the total earnings amount to £89,846 13s. 9d., as against £86,555 17s. 10d., an increase of £3,290 15s. 11d. compared with the half-year to June 30th, 1889.

The working expenses amount to £40,509 13s. 3d., as against £39,104 15s. 5d., an increase of £1,404 17s. 10d. This increase is attributable to a larger sum having been written off the steamers on account of depreciation (£1,031), to the rise in the price of coals, to the opening of a new station and to the larger volume of traffic.

Including the amount brought forward from 1889 (£3,248 16s. 6d.) and the dividend received upon the shares held in the "Platino" Company to June 30th, the balance to the credit of the revenue account is £59,970 17s. from which has to be deducted £13,220 for debenture interest, leaving £46,750 17s., of which £7,500 has been placed to the renewal fund and £5,880 to the debenture redemption fund. This leaves £33,370 17s. The directors recommend the payment of a dividend of 6s. per share, free of income tax, on the ordinary shares for the half-year, being at the rate of £4 per cent. per annum, carrying forward £5,751 7s. At the corresponding period last year the dividend was at the same rate.

Since the last half-year's report 30 "Platino" shares have been exchanged for 18 shares of this company.

The dividend warrants will be posted on November 14th.

An agreement for the absorption of the Montevidean and Brazilian Telegraph Company, Limited, will be submitted for the approval of the meeting. The undertakings are so closely allied that it is most desirable they should be brought under common control, and it is now proposed to purchase the above company by an issue of 5,300 ordinary shares of £15 each in the Western and Brazilian Telegraph Company, Limited, ranking for dividend earned after January 1st next. The agreement at present subsisting provides for the payment to that company of a percentage of the gross receipts of the Western and Brazilian Telegraph Company, Limited. This payment, forming a portion of the amount paid to the London Platino-Brazilian Telegraph Company, Limited, is a charge coming between the A and B debenture issue of the Western and Brazilian Telegraph Company, Limited. Consequently upon the arrangement now proposed, the proportion of this charge, hitherto paid to the Montevidean Company, will disappear.

The directors have the pleasure to state that after long and difficult negotiation, the Government of Brazil have authorised the

company to lay alternative cables. The thanks of the company are due to the Government of the United States of Brazil for this decision. Steps will be now taken to lay the lines immediately necessary.

The Chairman, after referring to the figures given in the report, said he would turn to what he would call the political aspect of the period under review. Shareholders would remember that when they met twelve months ago they were in a parlous condition. The Brazilian Government had absolutely refused to permit them to lay the loop cables; in face of that prohibition it was quite impossible to proceed. In other respects, too, the position at Brazil was not satisfactory. That was stating it in as mild a way as he could put it. Immediately after the last meeting there was a change of government in Brazil, and instead of dealing with an Empire, they had to treat with a Republican Government. He was glad to say their experience in regard to the loops was more satisfactory than with the previous Government. They firstly endeavoured to do all they could to obtain the support of the British Government. Lord Salisbury met them in a very fair spirit, and enquired fully into the matter, the result was in the company's favour, and they obtained the moral support of our Government. He considered it had done them a great benefit. Their representative in Brazil had been exceedingly active, and conducted the negotiations to the satisfaction of the board. With a great empire like Brazil, neither the company nor any Government could bring pressure to bear, they could only convince, and fortunately the strength of the case and the weight of the evidence did convince. He was pleased to say that they had authorised the laying of the cable. They were not to suppose that this cable would bring in any extra revenue, that was not the object, it was to enable them to fulfil their concessional obligations more effectively, and at the same time to safeguard the lines against interruptions. Then there was the forfeiture clause in the agreement, which was rendered safe by this extra cable. The special question before them that day was the purchase of the Montevidean Telegraph Company. At the present time they had an agreement with the Platino Company and the Montevidean. The latter company had a second charge upon their receipts, and if the shareholders approved, it was decided to absorb the interests in accordance with the statement in the report. In conclusion, he proposed the adoption of the report and accounts.

Mr. Earle seconded, and it was carried unanimously.

The Solicitor then read the proposed agreement, which met with the approval of the meeting, and the proceedings terminated.

### The Metropolitan Electric Supply Company, Limited.

SIR JOHN PENDER presided at the third annual meeting of the company, on Friday, at Winchester House. He said: The report will have explained to you our reasons for calling you together to-day. Under the Electric Lighting Act it is provided that companies with statutory powers must present their yearly accounts made up to December 31st to the Board of Trade not later than March 25th in the year following. You will remember that our company was formed in the autumn of 1888, and we naturally made up our first year's accounts to September 30th, 1889, and our general meeting was held to confirm those accounts in December last. The Board of Trade having intimated that they expected us in future to comply with these statutory requirements above referred to, we have found it necessary to alter the period of our financial year, which will end in future on the last day of December. We shall, therefore, call you together again in the spring for the purpose of submitting to you our accounts, and our meetings will henceforth be held in the beginning instead of the end of the year. I am glad to meet you to-day, for I am anxious to place before you such information as will enable you to share with the directors the confidence which they feel with regard to the position and prospects of the company. I have always felt, as chairman of other companies, that the more we strengthen the confidence between the directors and the shareholders the more smoothly we proceed and the more satisfactory is the business conducted. When we last had the pleasure of meeting you, I stated that we were supplying current for 15,000 lights, to 58 customers. We are now supplying current for 40,000 lights, to 300 customers. I may state that this number is largely in excess of that supplied by any other company in the United Kingdom, and that it is equal to about one-third of the total number of lights supplied in London by public companies. I am informed by our manager that we hold contracts for a further 10,000 lights, and that there are many more applicants who are negotiating with us for the supply. Indeed, I may say that it has been our experience that the number of applications grows steadily with and in proportion to our number of customers. I have in my hands a table showing the monthly increase of our lighting during the present year, which will give you some idea of the steady and assured growth of our business. I can also read to you a few of the testimonials we have received expressing entire satisfaction at the supply. That is another important point. I daresay you have all heard a great many complaints about the electric supplies of other companies. We have had nothing but complimentary letters from our various customers, which gives us after all the best assurance of the rapidly increasing confidence in our supply. I think it as well that I should read the testimonials, because they are important. Mr. Augustus Harris, of Drury Lane Theatre, says:—"I have no

hesitation in affirming that the electric light supplied by your company, the Metropolitan, is and has been in every way satisfactory, both as to quality and regularity." Mr. George Edwardes, of the Gaiety Theatre, says:—"In reply to your inquiry, the light you have been supplying is extremely satisfactory. There is not the slightest fault to find with it, the current being regular and the light brilliant." Mr. Kennedy, of the Exeter Hall, says:—"I am pleased to inform you that the installation of the electric light at the Central Young Men's Christian Association has proved a complete success. We are very pleased both with the continuity and the quality of your supply, and I shall be at all times pleased to afford any persons bearing your card an opportunity of viewing the light." Mr. Compton, of the Garrick Theatre, says:—"I beg to state that the lighting of this theatre is in every way satisfactory, both as to purity and regularity." Messrs. Hampton and Sons state:—"We have much pleasure in stating that the lighting of our premises upon the low tension system is most satisfactory, the whole 640 lamps giving a good steady light. We heartily congratulate you upon its success." I am just reminded by one of the directors, who is a great personal friend of Mr. Hare, of another excellent testimonial. Mr. Hare's statement as an actor was:—"I feel when I leave the theatre at night quite a different man from what I used to be when we had the gas. I find, because I breathe a pure atmosphere, that I can do my work better and more effectively, and altogether I find, even from a sanitary point of view, that it is immensely beneficial to theatres." You see I have not given you private testimonials, but those of our theatres, where it is so important that the light should not only be steady, but brilliant, and I think these evidences of what we are doing are a very striking proof of what we may expect in the future. I am now going to show you, gentlemen, the state of our lights, and how they have grown. On March 1st we had 16,000 lights, on April 1st 19,000, on May 1st 21,000, on June 1st 22,000, on July 1st 23,000, on August 1st 30,000, on September 1st 33,000, on October 1st 36,000, and on November 1st 40,000. You will observe that we have passed through the summer with a very fair average, and before the end of the year I expect to see at least 10,000 lights added. A glance at the map which we have prepared will show you the magnitude of our operations. You will notice the supply stations at Whitehall, Sardinia Street, Rathbone Place, and Manchester Square, together with the vast system of underground mains that have been carried out. Upwards of 40 miles of mains have been already made, and we roughly estimate that to complete our system at least double this quantity will be required. The following statistics on the subject of our areas may be of interest as showing their magnitude and importance. The average acreage is 3,105, houses 45,451, and the rateable value £4,500,000. The report states that we have obtained powers over Paddington. This district adjoins our other areas, and therefore will form part of our general system. We have obtained an advantageous site on the canal bank, and are about to commence active work, supplying, in the first instance, from our Manchester Square station. This will enable us to supply light immediately. I may here observe that we have no intention of applying for further districts at the present time. We do not consider that we shall be justified, with our present issue of capital, in incurring further responsibility and liability. We are satisfied that our present areas are amply sufficient both in size and importance to take up all our energies, and we believe that it is equally conducive to the interests of shareholders and consumers that we should develop the resources we have already acquired. Our capital at the present moment is £500,000. When I was examined before the committee which was appointed to inquire into the general electric lighting of London, I stated that I would not be satisfied as chairman of this company until our capital became at least £2,000,000. I hold precisely the same opinion to-day, after two years' experience of the work before us. I will now describe to you, in as few words as possible, the present condition of our supply stations. Our Whitehall station has caused a certain amount of disappointment owing to the fact that the large block of buildings called Whitehall Court, which it was originally constructed to light, and which we were under contract to supply as and when required, is not being occupied quite so speedily as we might have expected. Owing to this delay, we have not been able to utilise the station to its full capacity. We were, therefore, unable to count upon this station as a source of profit during the construction of our other stations, as at one time we had hoped to do. I may state that the Whitehall Court buildings are now being let satisfactorily, and I therefore hope that before long the station will be fully taken up. I informed you at our last meeting that we had given an order to double its capacity. This contract has been carried out. The machinery is now in working order, and we are ready to cope with any demand of it that may arise. We have at this moment 19,500 lights running from this station, and I may state that we have here a plant equal to supplying 50,000 lights. I very much hope that as many shareholders as possible will take an opportunity of visiting this station, as it will enable them to realise the magnitude of our undertaking. Orders to view our works can be had at the secretary's office. From this station one of the largest installations in London—that is, Drury Lane Theatre—is being lit. The next station that I shall refer to is Rathbone Place. I have already informed you of the circumstances which led us to purchase and develop this small station, which has existed for some time on this site. The new machinery which was ordered some time ago is now fast approaching completion; indeed, it would have been finished before now had it not been for many serious difficulties which have now, I am glad to say, been successfully overcome. These diffi-

culties were of a mixed character. In the first place, I daresay you know that if a man has a house alongside any electric installation, his belief is that he ought to bleed the company to some extent, on the ground that he is inconvenienced by the vibration. We have had injunctions without number, but all those injunctions were overcome in Rathbone Place. So much confidence have we in the value of this station that three days ago we purchased by auction the long lease of the building in which this station is situated. I may state that the price paid was a most reasonable one; in fact, we are advised that it is a great bargain, and the property will yield a very satisfactory return on the outlay. I may state that Rathbone Place is a most central station, and likely to give every light required. The number of lights we are now supplying from Rathbone Place is 6,000. This number could have been very largely increased, had it not been thought advisable during the construction operations to abstain from overloading this station. Manchester Square is the next station to which we attach very great importance. It is situated in the midst of the wealthy parish of Marylebone, and promises to be one of the most lucrative stations in our districts. You may remember that at the last meeting I informed you we had made advantageous terms with the London Electric Supply Corporation, by which we took over from them the existing network of mains in the Marylebone district. We were thus enabled to supply from this station the whole of the then existing demand as soon as our machinery was ready to run. By this means, although the machinery has only been at work for a period of four months, we are now supplying 11,000 lights. It is impossible to exaggerate the difficulties which are incurred in excavating the streets of London, and in avoiding the numberless pipes already laid. I may state that the whole of these works are being executed by our own men, under the superintendence of our engineering staff, and I can safely say that this is far more economical than that of employing contractors. These works have necessarily brought us into frequent contact with the local authorities, and with the County Council, and I should like to take this opportunity of expressing publicly our appreciation of the kindness and courtesy shown to us by the officials of these bodies. Turning to our financial position, I would remind you that owing to the circumstances under which we have called you together, we have no audited statement to submit. We have, however, gone very carefully into the matter, and I have no doubt that it will be satisfactory for you to hear that even with the necessarily small amount of our revenue at the close of last year and at the commencement of this, we have every reason to believe that we have more than paid our way. We are very pleased to be able to make this statement, for the following reasons, which we are anxious that you should carefully bear in mind. Our working expenses in the past, and even at the present, are, with one exception, the same, to all intents and purposes, as they will be when we are supplying double, nay treble, the number of lights which we are at present doing. Of course, the one exception is the item of coal. Otherwise, we have, at present, an engineering staff almost sufficient to cope with the maximum output we shall hereafter be called upon to supply. Hence the increase of working expenses bears no proportion to our increase in trade, and the larger our number of lights, the greater our profit on each light. The reason which makes it necessary to employ what may, at first sight, seem an excessive engineering staff at our stations, is that it is necessary that we should have a staff in the future sufficiently experienced to accept the responsibility which a full demand will impose; and it must also be remembered that our stations require almost as much supervision and attention now as at any time. I trust that I have made this sufficiently clear to you, because it will enable you to grasp some of our initial difficulties and to appreciate the importance of the statement that we have already made, that we are making a small profit. With the present large growth of business over what it was six months ago, and with an assurance of a continuous and steady increase from the present time, we believe that we are perfectly justified in stating, as we do in the report, that we look forward to a satisfactory dividend being earned during the ensuing year. I have heard some people say that a dividend might have been expected during the present year. I think this is a little unreasonable, inasmuch as the company has only been founded for a little more than two years, and has only been in possession of its Parliamentary powers for little more than one year. During this time the works which I have endeavoured to describe to you have had to be executed, and already we are able to announce that, with an average output during the present year of, say, 25,000 lights, and with our working expenses, as I have already endeavoured to show you, almost as heavy as they will ever be, we have run at a small profit. It does not, therefore, take much power of calculation to show that we may confidently look forward to a substantial return in the near future. I beg to move the adoption of the report and accounts.

Sir Robert N. Fowler, Bart., M.P., seconded the motion.

A Shareholder asked whether he understood that 30,000 lights represented £30,000.

The Chairman: Not necessarily. We are now selling our electricity by meter, and, therefore, it may be more or may be less. We must have a year or two's experience of how the meter works out before we can give a definite answer to that question.

The Shareholder: I wanted to know what the 100,000 lights mean.

The Chairman: We cannot answer that question yet, but if you ask my private opinion you might take it at about 10s. (A Member of the Board: More than that.)

A Shareholder: We shall get a key to it if you tell us the present revenue of the company.

The Chairman said he estimated the income of the present quarter at £10,000.

A Shareholder enquired whether the company was going to supply motive power as well as the light.

The Chairman replied that light was their primary object, and the demand was such at the present time that they had no time to turn their attention to supplying the motive power.

The motion was then put, and carried unanimously.

Mr. Giles, M.P., then moved the re-election of Sir James Anderson, Mr. J. Spencer Balfour, M.P., and Sir George Elliot, Bart., M.P., as directors of the company.

Mr. Dibley seconded the motion, which was agreed.

After the re-election of the auditors, a vote of thanks was accorded to the chairman and board, which was duly acknowledged, and the proceedings terminated.

### West India and Panama Telegraph Company.

IN accordance with the report published in our columns last week, the meeting of this company was held at Winchester House, on Wednesday, under the presidency of Mr. C. W. Earle. In taking the report as read, he said the report was the most satisfactory one which had ever been presented to the shareholders. It was not a very brilliant one at the best, and as long as the condition of the field remained as it is now, there was little probability, in his opinion, of its ever being a very brilliant result. Traffic receipts were slightly larger than before. Working expenses, other than repair, were less than usual. Repairs to cables were in excess of previous years, but this had the compensating advantage of their putting less to the reserve fund. They were within measurable distance of the riddance of the incubus that laid upon them in the shape of arrears of dividends on the preference shares. At the present time they owed £1 8s. 6d. per share on the second preference only, the total coming to £6,653. When they compared that with the £56,000 owed in 1884, he considered good progress had been made. At the request of the colonists, they had duplicated their lines. Although new traffic would not arise, there would not be the loss incident on interruption. The difficulty at Demerara was practically settled, and they would shortly lay a cable between Trinidad and Georgetown, Demerara. The ship, *Grappler*, was already lying in the Thames waiting for the cable. After referring to his watching the interests of the company at the Telegraphic Congress, he said traffic receipts were good and he was really beginning to have hope of a better state of things. But they must not run away with false impressions because they were coming out of bad times. Their receipts per mile were not half the average of any other cable company. He would ask ordinary shareholders not to expect that they were going to run into dividends, for they would soon lose the Martinique subsidy, the Guadeloupe subsidy would also cease in a few years, therefore he would not foster any exaggerated notions about the value of the shares.

In answer to questions he would leave the problem of receiving ordinary dividends to shareholders themselves.

A vote of thanks to the chairman terminated the meeting.

**Kelvinside Electricity Company, Limited.**—This company was incorporated in 1889 to supply electricity for illuminating and other purposes in the district of Kelvinside, the principal residential suburb of Glasgow. At the request of the local authority, and in order to efficiently supply the district, the directors resolved to increase the capital from £10,000 to £50,000, and accordingly the capital has now, by special resolution of the company, been increased to the above-mentioned sum of £50,000, in £1 shares. The unsubscribed capital is now offered for subscription, payable 2s. 6d. on application, 2s. 6d. on allotment, and the balance, as required, in calls not exceeding 5s., at intervals of not less than three months. This is the only company which has powers to supply electricity under the Electric Lighting Acts in that district. According to estimates, the capital outlay for plant required for a full installation of 30,000 glow lamps will amount to £40,000.

**Swan United Electric Company.**—At the meeting of the shareholders, which is to be held on the 25th inst., the directors will recommend a dividend of 10 per cent. for the year ended September 30th.

**An Elmore Copper Company for America.**—A prospectus is announced to be shortly issued of an Elmore copper company for the United States.

**Commercial Cable Company.**—This company has opened a branch office at 4, Charing Cross, S.W.

### TRAFFIC RECEIPTS.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending November 7th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £8,979.

## INDUSTRIALISM.\*

By W. B. ESSON.

(Concluded from page 554.)

But how does this affect the workman himself? Well, generally he works shorter hours than ever he did, and the purchasing power of the wage he receives is higher than ever. Individually, or in combination with others, he is free to bargain with his employer for the price of his labour, and nobody interferes. Yet, that he is far from satisfied with his lot, is a matter of daily observation. That the employer is displeased with his profits is also made manifest. That both fail to adjust their differences amicably is a fact which continues to be emphasised by constantly recurring strikes and lock-outs. In June of this year, for example, there were 79 strikes recorded, in July there were 99, and in August the number rose to 105. Some of these were of considerable magnitude and importance. The dock labourers and seamen headed the list with 16. The cotton trades come next with 15; the building trades follow with 12 and the miners with 9, the remainder being divided among the miscellaneous trades. Since then strikes in the iron and shipbuilding trades have been rife. As I write a strike in the tin-plate trade has just terminated, battalions of troops are held in readiness at Chatham to quell disturbance should the Beckton gas stokers strike, news comes that for the first time in the history of our iron manufacture all the Scotch furnaces, with the exception of those at Carron and Wishaw, are out of blast, the furnacemen having struck work. It must be remembered that each strike or lock-out is a confession of failure on the part of employers' associations or men's unions to adjust their differences in a reasonable spirit. These combinations exist for the purpose of settling labour disputes peaceably. A strike or lock-out is the last resource of either, and when this has taken place employer and employed stand related to each other as do two nations who, after vainly attempting to come to terms in the council chamber or refusing to submit to arbitration, determine to meet in the battle-field. The industrial battle, though generally a bloodless one, is inevitably disastrous, which, ever side gains, and these violent methods of settling disputes can only be regarded as constituting a virulent disease to which the industrial organism in its present stage of development is exceedingly liable. Nor can disease seize on one part of the system without producing, to a greater or less extent, functional derangement throughout the whole. A strike amongst the blast furnacemen, for instance, while it reduces the output of iron, throws upon the market a quantity of coal, which, before the strike, was used in smelting. This will make prices fall, and if the strike were long continued, would probably lead to a reduction of the miners' wages. Again, if the demand for iron keeps up, the price will rise as stocks are exhausted, and the price of manufactures in which iron and steel are employed, will rise accordingly. Owing to the rise, the demand in the shipbuilding and other iron-using industries will fall off, and the wages of those engaged in them may be in turn reduced. Of course I don't say that all these things will inevitably occur. What I mean is that the strike creates forces tending to make them happen, and which, if applied for a sufficiently long period, would doubtless have the result indicated. I use this illustration to show that every branch of industry hangs as it were upon another. Men think they are fighting the capitalist, when they are really fighting the workmen in a different branch of trade as well, and endeavouring to obtain a rise of wages partially at their expense. Emphasising this very point, there comes, while I write, the news that a thousand men are locked out in the engineering works at Newport, owing to a dispute between the smiths and boiler-makers.† As a matter of fact, profits and wages are derived from the same fund, employer and employed alike endeavouring to make the shares they respectively receive as large as possible.

Then outside the region of skilled labour, to which the observations in preceding paragraphs are mostly applicable, is a host of unskilled workman whose condition in many cases is, to say the least, precarious. Towards the Docks and the East-End drift this flotsam and jetsam of labour, and the attempts, successful to some extent, to form the dockers at different ports into a compact combination capable of bargaining for its services *en masse*, will be fresh in your memories. In the organised branches of this labour, however, strike has followed strike for the past twelve months in rapid succession. The Southampton riots are an affair of a month ago, and to-day steamers are lying in the London Docks with grain cargoes which corn porters refuse to unload, notwithstanding the advice of their union leaders to the contrary. The right of men to strike is admitted. The principle of free labour is, that if a man is dissatisfied he is at liberty to leave work and make a better bargain for his labour elsewhere. But while admitting the right, it is quite another question whether this right is being exercised to advantage or disadvantage. It seems here that the men have got quite beyond the control of the Union officers. Intoxicated with success they seem to think that there are no extremes to which they may not go. They are like an army which, in the triumph of

victory, exhibits insubordination, becomes disorganised and falls an easy prey to an enemy on the watch for advantages.

That strikes are a blot on Industrialism is admitted by all, nor is evidence wanting to show that they are conducted frequently in that spirit of militancy which is inherited from more barbarous ages. Coercion and intimidation are frequently resorted to. Rioting is common, and the strikers when arguing with the recalcitrant "blackleg" are not averse to occasionally emphasising the chief points by the aid of sticks or crowbars. In fact, gentlemen, we have in the conduct of a modern strike the old aggression appearing, we have the persecution, the intolerance and the oppression bred in our bones made manifest. We have all the evil of the human nature of our time revealed, which only the discipline of centuries to come can thoroughly eradicate.

But outside organisation of any kind is a shiftless throng of humanity living in rookeries, degraded, ill-clad, and yore fed. It is almost impossible for us to conceive how these creatures exist. As you know, competition is blamed for much of the evil in the East-End, and a Sweating Commission investigated the conditions under which the poor live but a short time ago. After collecting information regarding their lives from all sources, the Commission issued a bulky report, which is practically bare of suggestion. It is, in short, an acknowledgment that for the precarious wages and the state of misery revealed, the legislature can offer no remedy. Irremediable though it may be, however, it is still a blot on the industrial system.

But trade disputes, inadequate wages and poverty, are not the only blots observable. Writing of Glasgow, fifty years ago, a writer remarked that every Saturday and for the most part of Sunday, ten or twenty thousand workmen were more or less intoxicated, every farthing which could be spared being too often converted into ardent spirits. "The same individuals, who, a year before, were reduced to pawn their last shreds of furniture to procure subsistence, recklessly threw away the surplus earnings of more prosperous times in the lowest debauchery. The warnings of religion, the dictates of prudence, the means of instruction, the lessons of adversity, are alike overwhelmed by the passion for momentary gratification."\* That was written in 1840, but it is fairly true to-day. Anyone who studies closely the habits of the labouring classes in our large towns, cannot fail to be struck with the truth of Mr. Alison's observations. Improvidence, extravagance, and intemperance, are the besetting sins of the British workman. "Very few of them lay by in anticipation of times when work is slack; and the general testimony is that higher wages commonly result only in more extravagant living or in drinking to greater excess." From personal experience of workmen, I should say that in the large towns of England there is spent on an average from 15 to 20 per cent. of the earnings on beer and tobacco. Providence plays but an unimportant part in their lives. They listen to the voice of instinct and follow the promptings of unregulated desire, but for the most part lack that power of self-denial which should enable them to sacrifice present enjoyment in order to obtain future benefit. I speak of them now as a class, but that there are many exceptions to this general rule goes without saying. Nevertheless, it will be observed that the labourers' grievances are largely of their own creation. Though they talk much of co-operation, they continue to pour the possible capital down their throats or blow it in the air.

Here then is the position of things. The units composing the industrial community are exceedingly imperfect, consequently the present industrial system works imperfectly, production being hampered by continual bickerings, not only between employer and employed, but between the various sections of the latter as well. The earnings of industry after paying rent and taxes are divided into two parts, one payable to the capitalist for the loan of his capital, interest, the remainder constituting a wages-and-profits fund, which is divided between the managers and the workmen. So far as can be made out, it is the contention of the workman that the latter fund is unfairly divided, and in one or two words we may examine the conditions which regulate the division. First, however, it is necessary that the amount payable as interest be confused in no way with the amount devisable as earnings of management and earnings of labour among the producers. Though the same individual may be capitalist and manager, as often happens, the sums payable as interest and as earnings of management are to be considered quite separately. The amount due to interest is represented by the sum which the employer would get for the use of his capital if it were lent to a business man who managed a concern of the same kind as his own and having similar risks, is determined, in fact, by the market price of capital. This, as everyone knows, depends upon the demand for the use of money and the risk attending the lending of it. A Corporation whose security is excellent, can borrow readily at from 3 to 3½ per cent. But where there are various risks involved, as in most trading concerns, the borrowers have to raise money on mortgage debentures at 4½ to 5 per cent. Let it be understood that the capitalist has not fixed the amount of interest. That has been fixed by the competition for the aid of capital and the conditions under which it is lent. If the demand for the use of money is great, interest is forced up; if it gets less, interest falls. I conceive that the workman's objections are not to the interest the employer as a capitalist receives, but to the profits or, more properly, "earnings of management" which he takes from the wages-and-profits fund. Indeed, the workman by placing his savings in the bank may himself become a

capitalist to the extent of his means and get paid for the use of his money.

The amount due to interest being deducted then, the wages-and-profits fund remains to be divided amongst the producers. You are no doubt familiar with the saying that the amount of wages received by any particular section of the community is regulated by the supply of, and demand for, their particular kind of labour. But that there are secondary forces coming into action which, in conjunction with supply and demand, are beginning to exercise an important influence on the rate of wages must be apparent to all who have watched recent labour movements. "In an industrial conflict," said Prof. Marshall recently, "each side cares for the opinion of the public at large, but especially for that of those whose sympathy they are most likely to get; in the South Wales strike, for instance, the railway companies were specially anxious about the good opinion of the shippers and the engine drivers about that of the colliers."\* Thus we see that in addition to the influence of supply and demand the influence of public opinion is being brought to bear on questions relating to the adjustment of wages or to the distribution, if I might better put it, of the nett industrial returns. Supply and demand are, however, the great regulators, and upon these mainly the adjustment of wages depends. The capitalist is outside this adjustment. It is effected by competition among the various sections of workers for different kinds of labour; and the higher wages offered to any particular branch when the labourers become scarce in it form the inducement for others to come in, thus increasing the supply, and tending to bring the wages down to their normal level. Managers and business men are not exempt from the universal competition. If business power is scarce a proportionally larger amount is paid for management out of the wages and profits fund, and *ceteris paribus* less remains for the time being for division amongst other workers; if business power is plentiful, proportionally less is paid, and the workers temporarily benefit. If the employer is capitalist and manager at the same time the relation still holds good. True, he may pocket an apparently large sum as earnings of management, but on the other hand his enterprise, energy, ability and fertility of resource have to be paid for.

It is a common saying that a large return means a great risk, and in the case of businesses making large profits, the employer's share may very often be regarded either as the reward of genius and foresight, or as the higher interest he obtains for his capital under the exceptional risk of losing it. Competition between manufacturers in an ordinary way, however, is constantly tending to reduce earnings of management, and in bad times an employer, who is manager and capitalist as well, has very often to endure all the trouble and worry of managing his business for nothing, gaining, in the end, merely a bare interest for his money, such as could be obtained without trouble by lending it to someone else. In a joint stock concern the business is conducted by a manager and board of directors, who both receive wages of management, the capital being furnished by the shareholders. The latter receive a return as interest, and if this rises above the market rate, there are forces applied at once to bring it down to the normal in the form of new companies starting in the same business and entering into competition. What I wish to point out most clearly is that there is for each kind of labour a normal wage value, determined by the proportion which the wages in different employments bear, in order that a supply of workers in each may be forthcoming to meet the demand. Also the competition amongst the different classes, or, in other words, supply and demand, constitute the chief forces which tend to maintain wages at this normal value.

The various combinations of employers and employed have attempted to modify the relation between the wages of different labourers, but whether such combinations can effect, under present arrangements, any considerable change of a permanent character, is open to doubt. It seems to me that "corners" in labour, like corners in raw materials, are very likely to defeat their own ends, and that combinations which seek to obtain more than their proper share from the wages-and-profits fund, are unlikely to meet with other than that temporary success which adjusts their wages again to their normal level. But the present condition of industry is transitory, and only suited to the times. It represents a stage in the growth of Industrialism, and as fast as human nature changes to make a better state of things possible, just so fast will a better state be developed. "It is quite possible," as Mr. Spencer says, "to hold that when instead of devouring their captured enemies, men made slaves of them, the change was a step in advance; and to hold that this slavery, though absolutely bad, was relatively good, was the best thing practicable for the time being. It is quite possible, also, to hold that when slavery gave place to a serfdom under which certain personal rights were recognised, the new arrangement, though in the abstract an unequitable one, was more equitable than the old, and constituted as great an amelioration as men's natures then permitted. It is quite possible to hold that when, instead of serfs there came freemen working for wages, but held as a class in extreme subordination, this modified relation of employers and employed, though bad, was as good a one as could then be established." And so it may be held that at the present time, though the form of industrial government entails serious evils, those evils, much less than the evils of the past times, are as small as the

average human nature allows—are not due to any special injustice of the employing class, and can be remedied only as fast as men in general advance."\* And there are, here and there, signs of a higher industrial organisation. Co-operation proposed long ago a system, under which the workers are themselves the capitalists, is making progress. Profit sharing, a system which, after paying fixed wages and fixed earnings of management, allows of another distribution, *pro rata*, from the wages-and-profits fund, is, in several instances, being adopted. Only slowly, however, are these changes occurring, and several schemes had to be reported by the Labour Association in August as having "been temporarily abandoned, owing to the antagonistic attitude of the several trades unions." A most hopeful feature of this report, however, was that the question as regards the "workers sharing in losses as well as profits, had received a very practical answer from the workers of Messrs. Thomson and Sons, of Huddersfield, whose business was based on industrial partnership lines. Last year it was found impossible to pay any interest on share capital, and the workers resolved to pay interest themselves out of their own wages."† That spirit which freely recognises the claims of all, the sentiment of justice, mutual trust and mutual forbearance, are amongst the factors which will in time produce the industrial reformation.

In the course of this address I have talked of the industrial organism, and the term is not as might be supposed a mere figure of speech. In its gradual development from a simple to a complex form, in its continued differentiation of functions, in its ever-growing mutual dependence of parts, and in its increasing co-operation of members Industrialism manifests all the changes which take place in the course of organic evolution from the lowest to the highest type. And in the nature of man—the social unit—must be sought the cause of this gradual advancement. As amongst lower animals the increase of numbers and the struggle for subsistence has been the means of developing those special features exhibited by different species, so among men, the redundancy of numbers and the striving of each to gratify his desires have been developing a skill, intelligence, and self-control, which will in time lift him from savagery to the highest civilisation. That the present state of society is but transient has been already pointed out. It is the product of past and present, and represents the progress of evolution up to date. It has to be perceived that society is an aggregate of men, that it must therefore manifest in its institutions all the defects possessed by the units of which it is made up. That it is faulty in many particulars is apparent, but that it is the best—nay, that it is the only state possible for the time being, must, at the same time, be admitted. Only as fast as men, the units, advance, and as human nature improves, can a better state of society, the aggregate, arise.

People are loth to believe that institutions can only evolve, are impossible of manufacture. It is sometimes amusing to read the various manifestos of State socialists, ready with their cut-and-dried schemes to regenerate Industrialism, and professing that were their plans adopted, the traits which have characterised humanity through countless ages would forthwith disappear. And yet, perhaps, the published utterances of socialist leaders constitute the best proof that they are unfitted for a better condition of things. Men who talk of confiscating property without the slightest regard for the claims of the owners, manifest by their language their unfitness for a condition of society which implies a fuller recognition of men's rights. But some are foolish enough to believe that the passing of this or that Act would regenerate humanity, and that the men who show themselves to be guided by the instincts of robbers, are those who are to be instrumental in bringing about an industrial millenium. They have history to teach them, but they will not be taught. In olden times, the government imposed endless restrictions on industry, but one by one they have been removed, because found in time to be a mistake and discovered to intensify the evil they pretended to remedy. That the removal of these restrictions has been of immense service to industry most thinking men will admit. Nevertheless, in our day, a school has arisen which demands State interference of such a character that the restrictions of former times pale by comparison.‡ One can scarcely take up a daily paper which does not contain some attack on a State department for the perfunctory performance of its duties, and yet, notwithstanding this daily accumulating evidence, it is implicitly believed that for all evils to disappear, society has merely to be transformed into a huge government office.

That Socialism—inasmuch as the term implies complete adaptation to the social state—is the ultimate goal of society has been implied, but that this can be furthered by governments which exist because of the imperfections of humanity, is doubtful. "Perpetually, governments have thwarted and deranged the growth, but have in no way furthered it; save by partially discharging their proper function and maintaining social order. It is not to the State," quoting Spencer, "that we owe the multitudinous useful inventions from the spade to the telephone; it was not the State which made possible extended navigation by a developed astronomy; it was not the State which made the discoveries in physics, chemistry and the rest which guide modern manufacturers; it was not the State which devised machinery for producing fabrics of every kind, for transferring men and things from place to place, and for ministering in a thousand ways to our comforts. The world-wide transactions con-

ducted in merchants' offices, the rush of traffic filling our streets, the retail distributing system which brings everything within easy reach and delivers the necessities of daily life at our doors, are not of governmental origin. All these are the results of the spontaneous activities of citizens separate or grouped; "are, in fact, the results due to competition and to each one endeavouring to satisfy his own individual desires. So much has competition done; but those who have to do with Government departments know well that they are the last places in which enterprise or zeal, or even activity, is to be looked for. It will not do. The first requirement of progress is freedom of action. That everyone shall be at liberty to satisfy his desires in his own way, provided the equal liberty of others is not infringed, is the all-essential condition, for only in the endeavour to obtain their satisfactions have the intelligence and culture of modern times been developed.

I have referred to the improvidence of the working classes, but the influence which bad legislation has had in forming their improvident habits is generally ignored. As a matter of fact, they have been disciplined in improvidence for centuries, the punishment which extravagance should bring having been averted by the operation of the Poor Laws. Men have been taught that if they lack the foresight or self-denial entailed by preparation for old age, it is the duty of the State to make requisite provision for them, a premium having been thus put upon idleness, improvidence, drunkenness and licentiousness by taxing the virtuous and independent in order that the vicious might lead easy lives and multiply faster. Our State organised charity is a scandal to civilisation, but State Socialism, mark you, is but State charity on a gigantic scale. "It is a fact apparent to every thoughtful man," says a clever writer, "that the larger portion of the misery which constitutes our social question arises from idleness, gluttony, waste, profligacy, betting and dissipation. Reliance on industry, self-respect and energy, does not enter into the socialistic propaganda. In some vague way the poor man who is a voluptuous prodigal under the present order of things is to become wise and virtuous when property is held in common. But this is loose thinking which deceives no one who can think intelligently. He that is filthy will be filthy still, and he that is unjust will remain unjust in the absence of a moral change within."† All legislative attempts to equalise mankind must be futile, and not only futile, but mischievous, as their immediate effect, apart from evils more remote, is to increase the number of undeserving at the expense of the deserving. The human species obeys the laws of life by which all species are governed, and one of the fundamental generalisations of biology is, that fertility is determined by environment; that the rate of multiplication is always adapted to the conditions of existence. For every species there is a normal rate of increase, and if from any cause the relation existing between the organism and the environment becomes modified, a corresponding change in fertility results. Other things remaining the same if the conditions of life are made easier for a species, its rate of propagation increases, and from this universal law there is no escape. If the State, by relieving the citizen of responsibilities, voluntarily but imprudently undertaken, makes the conditions of his life less severe, self-reliance is displaced, self-respect is diminished and self-restraint is discounted. Relieved to an extent of the necessity for individual exertion, the rate of multiplication will rise above the normal, and only fall to it again if from increase of numbers the struggle for existence be raised to its former severity. The mean result of this interference on the part of the State is permanent increase of numbers in a lower grade of life, and permanent diminution in a higher, the struggle for existence being at the same time diminished as regards the former, and increased as regards the latter temporarily or permanently, as the case may be. Economists are fond of telling us that the "Standard of Comfort" of the people must be raised if the growth of population is to be checked. In the nature of things this means increased self-denial and a fuller recognition of responsibilities. It means an ideal which can only be realised by individual effort, a something to be by-and-bye gained by sacrifice now. The standard of comfort can be raised only by increased individuation. There is no other way. However implanted the incentive to rise must act from within and only by each progressive movement entailing more and more individuation, is the energy available for genesis diminished. The gospel of State Socialism is mere rubbish. To employ Mr. Arnold White's pithy summary, it is a gospel which equalises "genius and stupidity, industry and indolence, waste and thrift." It constitutes a removal of the forces which have operated from the dawn of civilisation till now to adapt men to the social condition. It comprises an unfitting process under which every deserving member of society gets less than the share he merits, in order that every undeserving member may get more.

From these remarks, it must not be thought that I am justifying the present state of Industrialism; far from it. My object has been simply to show that it is the best the average human nature of the time will permit of. It is a fact which must be ever kept in mind that human nature cannot be revolutionised by Acts of Parliament, nor can the evils which result from the average defects of humanity be eradicated by State measures. It is equally important to remember that human nature changes slowly, though it is utterly fallacious to assume, as some do, that

it changes not at all. It is the function of the Government to protect the citizen from foreign foe and civil aggressor, to enforce justice, to remove hindrances, and permit society, with fullest freedom, to work out its own salvation. If the present were the end, economists might well close their books and admit, with Carlyle, that their science were somewhat dismal. But to those who realise that the present is but a stage in development, and that the process which has already lifted us from savagery to semi-civilisation must continue till the adaptation is complete; to those who believe that in time the traits of a bye-gone savagery will disappear, the future of humanity is full of hope. Nor are signs wanting that we are making progress. Notwithstanding the various labour battles being fought around us, I think there is, amongst the more enlightened, evidences of fuller co-operation between the various sections of industry. Both masters and men are becoming a little less selfish, and are getting to trust each other more fully. Aggressiveness on each side is diminishing, and there is distinct indication of growing sympathy between them. As a result, a great development of profit-sharing arrangements, industrial partnerships and other schemes in which active co-operation is requisite, may be looked for in the near future. In these the hopeful see the beginning of the end.

But by no legislative legerdemain is the final goal to be reached, and it is through the purgatory of competition that we must pass to an industrial heaven. Remember the social state was forced on man by redundancy of numbers. "From the beginning, pressure of population has been the proximate cause of progress. It produced the original diffusion of the race. It compelled men to abandon predatory habits, and take to agriculture. It led to the clearing of the earth's surface. It forced men into the social state, made social organisation inevitable, and has developed the social sentiments. It has stimulated to progressive improvements in production, and to increased skill and intelligence. It is daily thrusting us into closer contacts and more mutually-dependent relationships."\* And with each advance in intelligence, with each demand on the increased individuation rendered imperative by the struggle for existence, there goes the inevitable diminution of fertility. "After having caused, as it ultimately must, the due peopling of the globe and the raising of all its habitable parts to the highest culture; after having brought all processes for the satisfaction of human wants to perfection; after having at the same time developed the intellect into complete competency for its work, and the feelings into complete fitness for social life; after having done all this, the pressure of population, as it gradually finishes its work, must gradually bring itself to an end."†

And here, based on history and on science, is foreshadowed a Utopia, in the presence of which even dreamers may well stand wonderstruck. From Sir Thomas More to Edward Bellamy, from Fourier to Grant Allen, the thinkers who have been struck with the misery of mankind have each in turn manufactured a system in accordance with their ideas of what ought to be. And having manufactured a system, they manufactured the human units to suit it. But they altogether ignore the power of the forces which have secured the partial adaptation to work out the adjustment to the end. That the harmony is far from complete is apparent; that man has instincts unfitted for social life is undeniable; but it is none the less sure that the process of adaptation to environment is gradually eradicating those hurtful instincts, and bringing into being emotions corresponding to complete harmony between faculties and surroundings. Nor will work be regarded in any sense a burden when this time arrives. Only pleasure is experienced by the exercise of faculties perfectly adjusted to requirements, and when the adjustment is complete, the efforts requisite for existence will constitute but a pleasurable activity. A time must be contemplated when the overflow of capital from rich countries into uncultivated or ill-cultivated regions of the earth must cease, and when for new works of vast magnitude its aid will be no longer required. Due to this lessened demand, the rate of interest will gradually fall, and the inducements to save large sums for one's personal benefit will diminish. The desire to possess great wealth arises because of the power it gives rather than the happiness it secures; but the desire for power, born of aggression, must eventually disappear with the growth of altruistic feelings. If Mr. Ravenstein's figures\* are to be trusted, barely two centuries will elapse before the globe is peopled with the six thousand millions it can support, and the condition attained under which the final adjustment of man to his environment must be effected. When this latter is accomplished, complete harmony will reign, and so we arrive at a Socialism, complete and all satisfying, achieved by forces older than humanity itself, and worked out by that Evolution which clasps the Universe in its all-powerful embrace.

**Bromley and the Electric Light.**—The Bromley Local Board has decided to make application to the Board of Trade for a provisional order to construct works, and to produce, store, supply and sell electricity for light, motive power, and all public and private purposes within its area.

### THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.

(Continued from page 568.)

Suppose we are working with the magnetisation of our iron pushed to about 16,000 lines to the square centimetre (i.e., about 150 lbs. per square inch, traction), requiring a magnetising force of about  $H = 50$ ; then, referring to the table, we see that each joint across the iron offers as much reluctance as would an air gap 0.0005 of an inch in thickness, or adds as much reluctance as if an additional layer of iron about  $\frac{1}{80}$ th of an inch thick had been added. With small magnetising forces the effect of having a cut across the iron with a good surface on it is about the same as though you had introduced a layer of air  $\frac{1}{80}$ th of an inch thick, or as though you had added to the iron circuit about 1 inch of extra length. With large magnetising forces, however, this disappears, probably because of the attraction of the two surfaces across that cut. The stress in the magnetic circuit, with high magnetic forces running up to 15,000 or 20,000 lines to the square centimetre, will of itself put on a pressure of 130 to 230 lbs. to the square inch, and so these resistances are considerably reduced; they come down, in fact, to about  $\frac{1}{30}$ th of their initial value. When Ewing specially applied compressing forces, which were as large as 670 lbs. to the square inch, which would of themselves ordinarily, in a continuous piece of iron, have diminished the magnetisability, he found the diminution of the magnetisability of iron itself was nearly compensated for by the better conduction of the cut surface. The old surface, cut and compressed in that way, closes as it were magnetically up—does not act like a cut at all; but at the same time you lose just as much as you gain, because the iron itself becomes less magnetisable.

The above results of Ewing are further represented by the curves of magnetisation drawn in fig. 48. When the faces of a cut were carefully surfaced up to true planes, the disadvantageous effect of the cut was reduced considerably, and, under the application of a heavy external pressure, almost vanished.

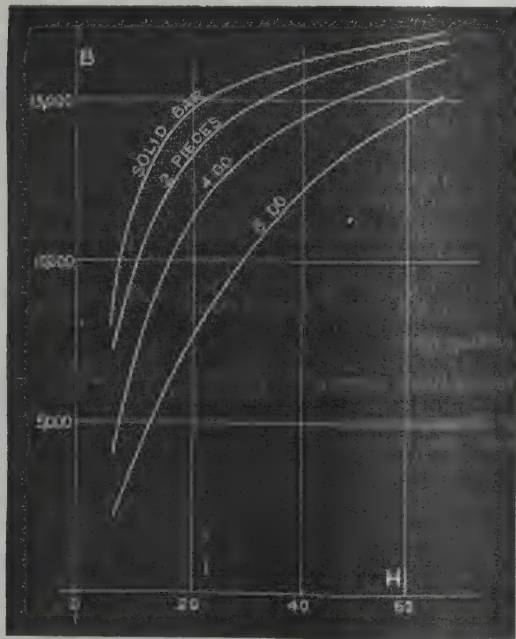

FIG. 48.—EWING'S CURVES FOR EFFECT OF JOINTS.

I have several times referred to experimental results obtained in past years, principally by German and French workers, buried in obscurity in the pages of foreign scientific journals. Too often, indeed, the scattered papers of the German physicists are rendered worthless or unintelligible by reason of the omission of some of the data of the experiments. They give no measurements perhaps of their currents, or they used an uncalibrated galvanometer, or they do not say how many windings they were using in their coils; or perhaps they give their results in some obsolete phraseology. They are extremely addicted to informing you about the "magnetic moments" of their magnets. Now the magnetic moment of an electro-magnet is the one thing that one never wants to know. Indeed, the magnetic moment of a magnet of any kind is a useless piece of information, except in the case of bar magnets of hard steel that are to be used in the determination of the horizontal component of the earth's magnetic force. What one does want to know about an electro-magnet is the number of magnetic lines flowing through its circuit, and this the older researches rarely afford the means of ascertaining. Nevertheless, there are some investigations worthy of study to which time will now only permit

\* Cantor Lecture. Delivered before the Society of Arts, January 27th, 1890.

me very briefly to allude. These are the researches of Dub on the effect of thickness of armatures, and those of Nicklès and of Du Moncel on the lengths of armatures. Also those of Nicklès on the effect of width between the two limbs of the horse-shoe electro-magnet.

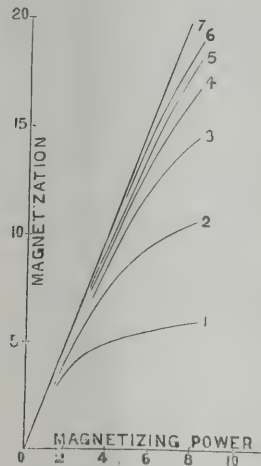

FIG. 49.—VON FEILITZSCH'S CURVES OF MAGNETISATION OF TUBES.

I can only now describe some experiments of Von Feilitzsch upon the vexed question of tubular cores, a matter touched by Sturgeon; Pfaff, Joule, Nicklès, and later by Du Moncel. To examine the question whether the inner part of the iron really helps to carry the magnetism, Von Feilitzsch prepared a set of thin iron tubes which could slide inside one another. They were all 11 centimetres long, and their peripheries varied from 6.12 centimetres to 9.7 centimetres. They could be pushed within a magnetising spiral to which either small or large currents could be applied, and their effect in deflecting a magnetic needle was noted, and balanced by means of a compensating steel magnet, from the position of which the forces were reckoned and the magnetic moments calculated out. As the tubes were of equal lengths, the magnetisation is approximately proportional to the magnetic moment. The outermost tube was first placed in the spiral, and a set of observations made; then the tube of next smaller size was slipped into it and another set of observations made; then a third tube was slipped in until the whole of the seven were in use. Owing to the presence of the outer tube in all the experiments, the reluctance of the air return paths was alike in every case. The curves given in Fig. 49 indicate the results. The lowest curve is that corresponding to the use of the first tube alone. Its form, bending over and becoming nearly horizontal, indicates that with large magnetising power it became nearly saturated. The second curve corresponds to the use of the first tube with the second within it. With greater section of iron saturation sets in at a later stage. Each successive tube adds to the capacity for carrying magnetic lines, the beginning of saturation being scarcely perceptible, even with the highest magnetising power, when all seven tubes were used. All the curves have the same initial slope. This indicates that with small magnetising forces, and when even the least quantity of iron was present, when the iron was far from saturation, the main resistance to magnetisation was that of the air paths, and it was the same whether the total section of iron in use was large or small.

I must leave till my next lecture the rules relating to the determination of the windings of copper wire on the cores.

#### APPENDIX TO LECTURE II.

##### CALCULATION OF EXCITATION, LEAKAGE, &C.

###### Symbols used.

- $N$  = whole number of magnetic lines (C.G.S., definition of magnetic lines, being 1 line per sq. centim. to represent intensity of a magnetic field, such that there is 1 dyne on unit magnetic pole) that pass through the magnetic circuit. Also called the *magnetic flux*.
- $B$  = the number of magnetic lines per square centimetre, in the iron; also called the *induction*, or the internal magnetisation.
- $B_{\text{iron}}$  = the number of magnetic lines per square inch in the iron.
- $H$  = the magnetic force or intensity of the magnetic field, in terms of the number of magnetic lines to the square centimetre that there would be in air.
- $H_{\text{air}}$  = the magnetic force, in terms of the number of magnetic lines that there would be to the square inch, in air.
- $\mu$  = the *permeability* of the iron, &c.; that is its magnetic conductivity or multiplying power for magnetic lines.
- $A$  = area of cross section, in square centimetres.
- $A''$  = area of cross section, in square inches.
- $l$  = length, in centimetres.
- $l''$  = length, in inches.
- $s$  = number of spirals or turns in the magnetising coil.

$i$  = electric current, expressed in amperes.  
 $v$  = coefficient of allowance for leakage; being the ratio of the whole magnetic flux to that part of it which is usefully applied. (It is always greater than unity.)

#### Relations of Units.

1 inch = 2.54 centimetres;  
 1 centimetre = 0.3937 inch.  
 1 square inch = 6.45 square centimetres;  
 1 square centimetre = 0.1550 square inch.  
 1 cubic inch = 16.39 cubic centimetres;  
 1 cubic centimetre = 0.0610 cubic inch.

To calculate the value of  $B$  or of  $B_{\mu}$  from the Traction.

If  $P$  denote the pull, and  $A$  the area over which it is exerted, the following formula (derived from Maxwell's law, see p. 899) may be used:—

$$B = 4,965 \sqrt{\frac{P \text{ kilos.}}{A \text{ sq. cm.}}};$$

$$B = 1,316.6 \sqrt{\frac{P \text{ lbs.}}{A \text{ sq. in.}}}; \text{ or}$$

$$B_{\mu} = 8,494 \sqrt{\frac{P \text{ lbs.}}{A \text{ sq. in.}}}.$$

To calculate the requisite cross section of Iron for a given Traction.

Reference to page 896 will show that it is not expedient to attempt to employ tractive forces exceeding 150 lbs. per square inch in magnets whose cores are of soft wrought iron, or exceeding 28 lbs. per square inch in cast iron. Dividing the given load that is to be sustained by the electro-magnet by one or other of these numbers, gives the corresponding requisite sectional area of wrought or cast iron respectively.

To calculate the Permeability from  $B$  or from  $B_{\mu}$ .

This can only be satisfactorily done by referring to a numerical table (such as Table II. or IV.), or to graphic curves, such as fig. 18, in which are set down the result of measurements made on actual samples of iron of the quality that is to be used. The values of  $\mu$  for the two specimens of iron to which Table II. refers may be approximately calculated as follows:—

$$\text{For annealed wrought iron, } \mu = \frac{17,000 - B}{3.5};$$

$$\text{For grey cast iron, } \mu = \frac{7,000 - B}{3.2}.$$

These formulæ must not be used for the wrought iron for tractions that are less than 28 lbs. per square inch, nor for cast iron for tractions less than  $2\frac{1}{4}$  lbs. per square inch.

To calculate the Total Magnetic Flux which a core of given sectional area can conveniently carry.

It has been shown that it is not expedient to push the magnetisation of wrought iron beyond 100,000 lines to the square inch, nor that of cast iron beyond 42,000. These are the highest values that ought to be assumed in designing electro-magnets. The total magnetic flux is calculated by multiplying the figure thus assumed by the number of square inches of sectional area.

To calculate the Magnetising Power requisite to force a given number of Magnetic Lines through a definite Magnetic Reluctance.

Multiply the number which represents the magnetic reluctance by the total number of magnetic lines that are to be forced through it. The product will be the amount of magneto-motive force. If the magnetic reluctance has been expressed on the basis of centimetre measurements, the magneto-motive force, calculated as above, will need to be divided by 1.2566 (i.e., by  $\frac{4\pi}{10}$ ) to give the number of ampère turns of requisite magnetising power. If, however, the magnetic reluctance has been expressed in the units explained below, based upon inch measures, the magnetising power, calculated by the rule given above, will already be expressed directly in ampère turns.

TO CALCULATE THE MAGNETIC RELUCTANCE OF AN IRON CORE.

(a.) If dimensions are given in centimetres.—Magnetic reluctance being directly proportional to length, and inversely proportional to sectional area and to permeability, the following is the formula:—

$$\text{Magnetic reluctance} = \frac{l}{A\mu};$$

but the value of  $\mu$  cannot be inserted until one knows how great  $B$  is going to be; when reference to Table II. gives  $\mu$ .

(b.) If dimensions are given in inches.—In this case we can apply a numerical co-efficient, which takes into account the change of units (2.54), and also, at the same time, includes the operation of dividing the magneto-motive force by  $\frac{4}{10}$ ths of  $\pi$  (= 1.2566) to reduce it to ampère turns. So the rule becomes

$$\text{Magnetic reluctance} = \frac{l''}{A''\mu} \times 0.3132.$$

*Example.*—Find the magnetic reluctance from end to end of a bar of wrought iron 10 inches long, with a cross section of 4 square inches, on the supposition that the magnetic flux through it will amount to 440,000.

To calculate the Total Magnetic Reluctance of a Magnetic Circuit.

This is done by calculating the magnetic reluctances of the separate parts, and adding them together. Account must, however, be taken of leakage; for when the flux divides, part going through an armature, part through a leakage path, the law of shunts comes in, and the nett reluctance of the joint paths is the reciprocal of the sum of their reciprocals. In the simplest case the magnetic circuit consists of 3 parts (1) armature, (2) air in the two gaps, (3) core of the magnet. These three reluctances may be separately written, as in the Table in next column.

If the iron used in armature and core is of the same quality, and magnetised up to the same degree of saturation,  $\mu_1$  and  $\mu_3$  will be alike. For the air-gaps  $\mu = 1$ , and therefore is not written in.

If there were no leakage, the total reluctance would simply be the sum of these three terms. But when there is leakage, the total reluctance is reduced.

	For centimetre measure.	For inch measure.
1. Armature ...	$\frac{l_1}{A_1 \mu_1}$	$\frac{l''_1}{A''_1 \mu_1} \times 0.3132$
2. The Gaps ...	$2 \frac{l_2}{A_2}$	$2 \frac{l''_2}{A''_2} \times 0.3132$
3. Magnet Core..	$\frac{l_3}{A_3 \mu_3}$	$\frac{l''_3}{A''_3 \mu_3} \times 0.3132$

To calculate the ampère-turns of Magnetising Power requisite to force the desired Magnetic Flux through the reluctances of the Magnetic Circuit.

(a.) If dimensions are given in centimetres the rule is:—

Ampère-turns = the magnetic flux, multiplied by the magnetic reluctance of the circuit, divided by  $\frac{4}{10}$ ths of  $\pi$  (= 1.2566).

Or, in detail, the three separate amounts of ampère-turns required for three principal magnetic reluctances are explained as follows:—

$$\text{Ampère-turns required to drive } N \text{ lines } \left\{ \begin{array}{l} \text{through iron of armature ...} \end{array} \right\} = N \times \frac{l_1}{A_1 \mu_1} \div \frac{4\pi}{10},$$

$$\text{Ampère-turns required to drive } N \text{ lines } \left\{ \begin{array}{l} \text{through the two gaps ...} \end{array} \right\} = N \times \frac{2l_2}{A_2} \div \frac{4\pi}{10},$$

$$\text{Ampère-turns required to drive } vN \text{ lines } \left\{ \begin{array}{l} \text{through the iron of magnet core} \end{array} \right\} = vN \times \frac{l_3}{A_3 \mu_3} \div \frac{4\pi}{10},$$

And, adding up:—

$$\text{Total ampère-turns required} = \frac{10}{4\pi} N \left\{ \frac{l_1}{A_1 \mu_1} + \frac{2l_2}{A_2} + \frac{vl_3}{A_3 \mu_3} \right\},$$

(b.) If dimensions are given in inches, the rule is:—Ampère-turns = magnetic flux multiplied by the magnetic reluctance of the circuit. Or, in detail:—

$$\text{Ampère-turns required to drive } N \text{ lines } \left\{ \begin{array}{l} \text{through iron of armature ...} \end{array} \right\} = N \times \frac{l''_1}{A''_1 \mu_1} \times 0.3132,$$

$$\text{Ampère-turns required to drive } N \text{ lines } \left\{ \begin{array}{l} \text{through two gaps ...} \end{array} \right\} = N \times \frac{2l''_2}{A''_2} \times 0.3132,$$

$$\text{Ampère-turns required to drive } vN \text{ lines } \left\{ \begin{array}{l} \text{through iron core of magnet ...} \end{array} \right\} = vN \times \frac{l''_3}{A''_3 \mu_3} \times 0.3132;$$

And, adding up:—

$$\text{Total ampère turns required} = 0.3132 N \left\{ \frac{l''_1}{A''_1 \mu_1} + \frac{2l''_2}{A''_2} + \frac{vl''_3}{A''_3 \mu_3} \right\}.$$

It will be noted that here  $v$ , the coefficient of allowance for leakage, has been introduced. This has to be calculated as shown later. In the meantime it may be pointed out that, in designing electro-magnets for any case where  $v$  is approximately known beforehand, the calculation may be simplified by taking the sectional area of the magnet core greater than that of the armature in the same proportion. For example, if it were known that the waste lines that leak were going to be equal in number to those that are usefully employed in the armature (here  $v = 2$ ), the iron of the cross might be made of double the section of that of the armature. In this case  $\mu_3$  will approximately equal  $\mu_1$ .

To calculate the Coefficient of Allowance for Leakage,  $v$ .

$v$  = total magnetic flux generated in magnet core + useful magnetic flux through armature. The respective useful and waste magnetic fluxes are proportional to the permeances along their respective paths. Permeance, or magnetic conductance, is the reciprocal of the reluctance, or magnetic resistance. Call useful permeance through armature and gaps  $u$ ; and the waste permeance in the stray field  $w$ ; then

$$v = \frac{u + w}{u}$$

*w* may be estimated by the Table VIII. given on p. 567 (ELEC. REV., November 7th), or other leakage rules, but should be divided by 2 as the average difference of magnetic potential over the leakage surface is only about half that at the end of the poles.

#### RULES FOR ESTIMATING MAGNETIC LEAKAGE.

(I. to III. Adapted from Prof. Forbes's rules.)

*Prop. I.* Permeance between two parallel areas facing one another.—Let areas be  $A_1''$  and  $A_2''$  square inches, and distance apart  $d''$  inches, then:—

$$\text{Permeance} = 3.193 \times \frac{1}{2} (A_1'' + A_2'') \div d''.$$

*Prop. II.* Permeance between two equal adjacent rectangular areas lying in one plane.—Assuming lines of flow to be semicircles, and that distances  $d_1''$  and  $d_2''$  between their nearest and furthest edges respectively are given, also  $a''$  their width along the parallel edge:—

$$\text{Permeance} = 2.274 \times a'' \times \log_{10} \frac{d_2''}{d_1''}.$$

*Prop. III.* Permeance between two equal parallel rectangular areas lying in one plane at some distance apart.—Assume lines of leakage to be quadrants joined by straight lines.

$$\text{Permeance} = 2.274 \times a'' \times \log_{10} \left\{ 1 + \frac{\pi (d_2'' - d_1'')}{d_1''} \right\}$$

*Prop. IV.* Permeance between two equal areas at right angles to one another.

Permeance (if air angle is  $90^\circ$ ) = double the respective value calculated by II. or III.

Permeance (if air angle is  $270^\circ$ ) =  $1\frac{1}{2}$  times the respective value calculated by II.

If measures are given in centimetres these rules become the following:—

$$\text{I. } \frac{1}{2} (A_1 + A_2) \div d;$$

$$\text{II. } \frac{a}{\pi} \log_e \frac{d_2}{d_1};$$

$$\text{III. } \frac{a}{\pi} \log_e \left( 1 + \frac{\pi (d_2 - d_1)}{d_1} \right).$$

*Prop. V.* Permeance between two parallel cylinders of indefinite length.

The formula for the reluctance is given on p. 566 (ELEC. REV., November 7th): the permeance is the reciprocal of it. Calculations are simplified by reference to Table VIII.

(To be continued.)

### NEW PATENTS—1890.

16752. "Improvements in electrical switches." T. R. ANDREWS and T. PREECE. Dated October 21.

16792. "An improved arrangement of regulating device for electric arc lamps." A. DE PUYAT. Dated October 21.

16809. "Improvements in electric blank heating and feeding apparatus for forging machines." G. D. BURTON. Dated October 22. (Complete.)

16811. "The improvement of switchboards for the regulation and control of electrical currents." P. G. POCHIN. Dated October 22.

16835. "An improved electrical conductor for fitting in mine shafts and underground haulage roads for electrical signalling purposes." W. CAIRNS and A. F. MABON. Dated October 22.

16837. "Improvements in the manufacture, construction, and building up of secondary battery elements, electrodes or plates." J. E. DOUGLASS. Dated October 22.

16889. "Improvements in electromotors." R. KENNEDY. Dated October 23. (Complete.)

17018. "Improved joints or connectors for uniting wires or cables, temporarily or otherwise, for electrical or other purposes." W. BISHOP. Dated October 24.

17062. "Improved electric switch." J. P. BAYLY. (Communicated by C. Herrick, United States.) Dated October 25.

17063. "An improved electric lampholder and switch combined." J. P. BAYLY. (Communicated by C. Herrick, United States.) Dated October 25.

17108. "Improvements in dynamo-electric machines." G. PITT. (Communicated by R. Thury, Switzerland.) Dated October 25.

### ABSTRACTS

#### OF PUBLISHED SPECIFICATIONS 1889.

13168. "Improvements in means for supporting electric lamps and in conductors therefor." A. McCANDLISH. Dated August 21. 6d. To a permanent or temporary magnet there is attached an elastic medium, such as springs made of metal or India-rubber,

for arresting the vibration; to this elastic medium is fixed or suspended the "electric" lamp. 3 claims.

13510. "Lamp shades or reflectors for electric lamps." W. B. LAWRENCE. Dated August 27. 8d. The inventor takes a glass or other bulb, and beneath the apex or neck removes a lateral section thereof. He then surrounds the lamp with the remainder, thus forming a shade and reflector, and it is attached in the following manner:—The globe fits into a sleeve, which contains light wires. The sleeve in turn fits into a socket, on a bracket to which the light wires are applied, and it is held in position and attached by means of shoulder pins, fitting into a groove in the interior of the socket. 4 claims.

15958. "A method of and appliances for preventing excessive heating or undue expansion of electric mains or service conductors through excess of electricity, and for utilising such excess." F. W. ENGELBACH and E. B. BRIGHT. Dated October 10. 8d. A metallic slide bar, attached to the rod of the governor of the engine driving the dynamo-electric machine, is so arranged that it is lifted or lowered by the rising or falling of the governor. The slide bar is electrically connected to one pole of the dynamo-electric machine and makes contact successively with a series of metallic springs insulated from one another. If the apparatus is used simply to neutralise any excess of electricity in the electric conductors the springs are electrically connected to the other pole of the dynamo machine, but the size of the conductor from each spring is such that each spring acts as a shunt between the two poles of the dynamo-electric machine; thus gradually increasing the proportion of electricity diverted from the electric mains or service conductors as the governor rises. 5 claims.

16537. "Improvements relating to insulators for electric wires and to supports therefor." D. RYLANDS. Dated October 19. 8d. Instead of passing the wire around or on one side of the insulator as heretofore, the inventor arranges the insulator lengthwise in the direction of the wire to be insulated, and passes the said wire through a hole formed in the said insulator. 4 claims.

16978. "Improved arrangement of conductors for electric series traction." J. M. M. MUNRO. Dated October 28. 8d. Relates to the arrangement of conductors for carrying the electricity to the motors of vehicles driven by electricity, the object of which is to provide a system of conductors for series traction which will allow of having greater length of continuous conductors than has hitherto been in practical use. In this system the whole circuit is laid off in a number of sections, which may be equal to the greatest number of cars or trains intended to be run upon it at one time. 6 claims.

17115. "Improvements in electro-magnetic telegraph apparatus." F. X. BACHMANN. Dated October 30. 6d. The inventor provides a core connected to or made in one piece with the two pole pieces. The core is wound with a fine wire. The pole pieces rest upon a metal bar lying parallel with the axis of the core. The armature is pivotted to move in a plane parallel with the axis of the core, and at a point therein equidistant between the two pole-pieces. 3 claims.

17276. "An improved socket and adapter for incandescent electric lamps and other electrical purposes." G. DONOVAN and W. DONOVAN. Dated October 31. 8d. Consists in the construction of an adapter or socket of a form similar to the cap of the ordinary incandescent lamp, which is carried out by forming a cylindrical body having a projecting shoulder of smaller diameter of boxwood, porcelain, or any other suitable insulating material. Upon the said projecting shoulder a small piece of tube of brass or other material is fitted of such a size as to fit into the ordinary lamp holder, pins being arranged on the outside of the said tube, in order to engage as a bayonet joint in the lamp holder in the usual manner. Upon the opposite side of the cylindrical body to that on which the brass tube is fitted, a circular recess or groove is provided either of V or other suitable shape, and from such recess two tubes of brass or other suitable conducting material are led through the body of the socket or adapter, and extend to the same distance as the brass socket tube. Upon the ends of these contact-making tubes suitable contact plates of copper or other equivalent material are arranged. The space within the brass socket tube around the said contact-making tubes is filled with plaster of Paris or other suitable material, so thoroughly insulating the conductors from one another and from the surrounding fittings. 4 claims.

17317. "Improvements in electric measuring and regulating apparatus for use with alternate currents." W. T. GOOLDEN and SYDNEY EVERSHED. Dated November 1. 8d. The object of the invention is to render electro-magnetic measuring instruments, regulating apparatus, and integrating meters, with or without iron or other kindred material as the magnetic medium, suitable for the accurate measurement] and regulation of alternate currents. 6 claims.

17387. "Improvements in electric meters." J. OULTON and J. EDMONDSON. Dated November 2. 8d. Relates mainly to electric meters in which the current to be measured is made to retard or accelerate the vibrations of a pendulum or chronometric balance, the amount of such retardation or acceleration being the measure of the current consumed. 4 claims.

17763. "Improvements in or applicable to electrical switchboards and switches." F. L. RAWSON and W. WHITE. Dated November 7. 8d. The inventors form in an electrical distributing switchboard the connections to the two poles of the main circuit by means of two main bars of metal, which may be castings

arranged so that the connections are all on the surface of the board, the two mains of the dynamo being connected to these two bars at one end of each by means of suitable cable connectors. One of the main bars is made with projections on one side, which projections are bevelled off to allow the brushes as they are turned round to rise to the top of the bar, and so make a good contact for one end of the switch brush. The other contacts of the switch brushes, which may also be castings, are bevelled off where the brushes rise on to them, and are provided with projections to receive the terminal screws under which the ends of the fuses are clamped, the other ends of the fuses being clamped under terminal screws on to suitable plates, at the other end of which plates cable connectors for the external circuits are clamped down with a nut. All the contact plates on the surface of the board are the same height, and are all flat on the top, so that they can be all planted on the board, and filed or planed over at one operation, thus making the production exceedingly cheap and simple. 4 claims.

18343. "Improved safety cut-out apparatus for a network of multiple electrical conductors." SIEMENS BROS. & Co. (Communicated from abroad by the firm of Siemens and Halske, of Berlin.) Dated November 16. 8d. Claim:—In a network of multiple electrical conductors, the use of safety cut-out apparatus connected with all the conductors, and so constructed and arranged that when the current in one of the conductors becomes too strong, it effects automatically the interruption of all the conductors, such apparatus consisting either of an inflammable mass in which the safety fuses of all the conductors are imbedded, or of an electro-magnet included in the circuit of each conductor, the armature of which controls a cut-out switch for all the conductors, or of any equivalent device for carrying out the above-named object, substantially as described.

## CORRESPONDENCE.

### The British Insulated Wire Company, Limited

I notice in the current issue of your valuable paper, which has just come to hand, a short reference to the "Norwich" cables made in this country by the British Insulated Wire Company, Limited, in which you remark, "There is apparently no attempt to make any test which the merest tyro in a submarine cable factory would know to be necessary." You are good enough to qualify your critique by the term "apparently," and I am glad to be able to inform you that this defect is apparent only and not real.

Of course a new and untested material before coming into practical use requires to be experimented upon exhaustively, but where a given class of cable has been in practical use for some years, doing its duty successfully under various conditions, many of which are most trying, I think you will agree with me that the value of laboratory tests are somewhat discounted as a means of proving the capabilities of manufactures under a given process.

At the same time, as an independent opinion though useful is but that of an individual, and therefore likely to be slightly faddish, it is most satisfactory to have such judgment corroborated by all possible tests, trials, and coincidence of opinion generally, and this, be it noted, is the case on the matter referred to.

The company have been good enough to hand me for perusal several reports by distinguished scientists and well-known practical men, and I find that the figures quoted are those, within a very small percentage, obtained in the tests made by me. On careful consideration of my letter to the British Insulated Wire Company, Limited, you will see that it is only a "memo." prior to furnishing a report which is now completed, and contains all the possible data and results of a series of tests on the "Norwich" telephone and electric light cable. Also I referred to some experiments on "Hygrometric absorption" in my memo., so that the cable has been "submitted to the action of damp, and its insulation has remained unimpaired." Regarding your interpretation of my remark as to maintenance of high insulation at a high temperature, reference might be made to some statements by Mr. David Brooks, in January, 1886, as follows:—

"All of the recognised insulating materials are affected by temperature. The insulating property of

gutta-percha is 100 times higher at + 100° F. than at the freezing point." "Textile coverings like cotton, flax, hemp, jute and manilla show entirely different results. These materials in a natural state may be classed as conductors."

The company are in possession of complete and reliable data of a set of tests made in different ways and at different times, and no doubt they will be prepared to furnish you with these at an early date for your complete satisfaction.

Charles H. Yeaman.

Electrical Testing Room, City of  
Liverpool, November 8th, 1890.

Being a subscriber to your valuable journal, and a pretty constant reader, I saw the notice you honoured the British Insulated Wire Company with in your issue of the 7th inst., and have nothing to complain of in your remarks except, perhaps, the concluding sentence, viz., "the practice (so common) of attracting the unsuspecting public by reports which are not worth the paper they are written on, cannot be too severely condemned."

Had it not been that the company must be advertised to comply with the terms of the underwriting letter, the "unsuspecting public" would never have been asked to buy a share, as every underwriting contract being by personal friends was a *bonâ fide* purchase and not a speculation.

I had intended, and still intend, sending you fullest details of tests of this make of cable, and hope to do so within the next few days.

R. E. Crompton, Esq., is not acting in the dark, as he was good enough to put some of these cables into service in the early part of this year, and has nothing but praise for them.

My object in troubling you with this letter is to show you that no imposition on the public was designed, or a precedent for a very different policy could readily have been found.

J. B. Atherton.

November 11th, 1890.

### Life of Glow Lamps on the Series System.

In the discussion on Mr. Bernstein's Paper on the "Series System," read in the Institution of Electrical Engineers in 1886, Mr. Mordey expressed the opinion that lamps on a circuit of constant current must of necessity be shorter lived than lamps on a parallel circuit, the reason being that the resistance of lamps rises in course of time. If placed in parallel, they will then take less current, give less light, but have a considerable preservative power.

This view appears very plausible, and it will therefore be of interest to many readers to hear that a Bernstein lamp, which was placed in a circuit of constant current of 10 ampères in Niagara-in-London, has been in use more than three years every night except Sundays, and has already lasted more than 10,000 hours. During the present year it has been run 12 hours daily.

The system on which this lamp has been run is known as the Wood's system of arc lighting, and is owned by the Fort Wayne Electric Company, of Indiana.

Frank Lott,  
Electrical Engineer in charge,  
"Niagara-in-London."

November 7th, 1890.

[A. E. MUIRHEAD.—The telephone receiver you mention is apparently similar to that of Silvanus Thompson, the Stanhope, and others, and also to the one known as the "English Mechanic" receiver. If this is so, we believe it is no infringement of the Bell patent.—EDS. ELEC. REV.]

OUR DEFENCES.

THE subject of our defences is one which, possibly, it may be argued, does not strictly come within our province. It is not for a technical journal, professedly an electrical organ, to encroach upon what may be regarded as the domain of military or naval administration. Nor is it in any such spirit we approach the question, but rather as a representative of a factor—and an important factor—of that force which must form an element in the consideration of the subject.

Regarded from that narrow and circumscribed standpoint which looks at everything which is said and done, as the outcome of some selfish and personal interest, it will possibly be said that the remarks we have to offer are prompted in the interest of that branch of manufacture, and in the extension of that application of science which we represent. We will ask our readers, and our critics, to believe that we are capable of being animated, as we think we have not unfrequently shown, by other and more noble desires. The subject to which we desire to direct attention is doubtless one which may be more forcibly brought under the notice of the general public by our influential daily contemporaries, and we very heartily and very earnestly seek their co-operation.

It is now some year or more since we, in referring to the Naval manœuvres which had then come to their close for that year, called attention to the need of providing for the defence of many of our chief seats of mercantile naval commerce. The proceedings of the attacking force then illustrated how deplorably all our mercantile ports were open to attack, and we suggested that it would be well for the Government and the nation to take into consideration what would be the position of our commerce and our coast defences were we brought face to face with a real, instead of an artificial, enemy. We then suggested the desirability of establishing, at various points, dépôts of such material as might be stored, against the moment of its requirement. What steps have been taken towards

this, or towards any other means of defence, we fear has been exceedingly small; so small, that were England placed upon its defence to-morrow, her only chance would be that sheer bulldog tenacity—that determination never to be beaten which has characterised our forefathers in all our engagements, which would have, if possible, to pull us through. How far this would be successful with the scientific advances made by other nations is an open and a somewhat doubtful question. British pluck and British determination will go a long way where the weapons are equal, but is our provision on an equality with our neighbours. What steps are we taking for the defence of our commercial ports? As we previously pointed out, supposing it should become necessary to lay down a series of marine mines for this purpose, what provision in men and material is being made towards it? Is it not a fact that, so far as the country is concerned, there exists but one recognised source, viz., the Royal Engineer corps, for furnishing the former? Is it possible they could meet such demands, and at the same time comply with the requirements of that duty for which they were primarily created? Why, then, if civilian aid is to be called upon, are we not establishing it? We have no lack of volunteer enterprise for other branches of military or naval defence; but here we are dealing with something novel—something which requires, and must have, the support and recognition of the Government; which must, in fact, be initiated by that authority. Are we so supine as to suppose there will be time to organise all this when we get notice of its need? To be prepared is not to court war—rather the reverse. Neither England nor any other country can afford to stand idly by waiting till the time comes for action. All must be prepared, so that should that time, unhappily, ever come, action may be prompt and decisive, as we may rest assured it will be by others, if not by ourselves.

Our attention has been more than ever forcibly directed to the subject by a paper read before the New York Electrical Society last month, and which we pub-

lished in full in our previous number. This paper was from Lieutenant Fiske, of the United States Navy, and is entitled "The Civilian Electrician in Modern War." Lieutenant Fiske's name will probably be for ever associated with the tactics of American naval warfare and coast defence, for to him certainly will belong the inception and the credit of applying electrical science to those objects. The paper is one which might well be considered by our authorities and by the public at large interested in home defences. It is necessary we should be alive to the fact that electricity, as stated by Lieutenant Fiske, "has come into use as one of the great factors in warfare, both on sea and shore, not as an adjunct merely, as for lighting ships and forts, but as a vital element in the handling of weapons in actual battle, and in the construction of new instruments which accomplish things heretofore impossible." The modern war ship, if to be used as a concentrated mass of energy, to overwhelm and crush her adversary, must be capable of being handled, as Mr. Fiske states, from one central point, by one individual, so placed that he can see and command all around him. The handling of such a vessel, the direction of her guns, the moment of their discharge—all this, together with a multitude of other minor matter, all come within the provision of electrical agency. The illumination, the healthfulness of the vessel, are aided by its means, and by its means she may surround herself by a cordon of explosives against which her opponent dare not dash herself. On board ship the fighting officer must be in the midst of the smoke of the battle, but on land this need not be so. Stationed apart from the smoke, the noise, and confusion of the attack he may, at a distance sufficient for his purpose, observing all that passes, guide the defence by the aid of that power which also enables the gunner to concentrate his battery, and to discharge it at the point, and at the moment when it shall deal its most efficient blow.

Still, multitudinous as are the applications of electricity to forts and to ships, in torpedo or submarine mining, it will be found of no less importance; and, as we have previously urged, no more ready, no more speedy means of preparing for defence exists than is to be here found. But how can it be used, how can it be installed without men capable to handle such work. It is idle to look to the War Office resources as they at present stand. Either the War Department should establish a corps, sufficiently large to deal promptly with the entire coast defence, or the Government should institute local volunteer corps, officered and manned, subject of course to the responsible local military authority, by local residents. Every facility should be afforded such corps for practice. Depôts of material should be established, and everything necessary for actual defence, as far as possible, provided for. The Mersey, the Clyde, the Tyne, the Thames, and other important and strategical points would not be slow were it announced that the Government were prepared to deal with this subject in a broad and liberal manner, in responding to such a call. In no other way do we see it possible to approach this most important question.

We heartily commend Lieut. Fiske's paper to the perusal of our naval and military authorities. From it they will learn to what extent others are preparing for the dire emergency of war—a war which, when it does come, will be one in which science, and especially electrical science, will play the most important part. When war comes, no matter what our preparation may be, it will still find plenty wanting. Let our preparations be ever so great, let us feel that we are even prepared, and there will yet be far more to do than can be done at the time. How, then, if we are found as we are at present? We heartily trust that our contemporaries may, as we suggest, take the question up and bring to bear upon it their influence, and that the result may be that movement we are so desirous of seeing—a movement on the part of the authorities to provide the necessary means for the defence of our coasts, and a responsive movement on the part of those who possess the ability and the time to volunteer their services for the work.

---

Count Mattei's  
Remedies.

WITH commendable zeal Mr. Alfred W. Stokes, public analyst to Paddington, Bethnal Green, and St. Luke's, has undertaken an investigation into the genuineness of the "Electricities" remedies of Count Mattei. Mr. Stokes states, as the result of his investigations, that as regards the liquids "To delicate test-paper they were perfectly neutral. Vegetable extracts are usually either alkaline or acid; even if neutral when fresh, they speedily change. They had the following characters:—Colour, odour, taste, polarity, metals, and alkaloids, none; specific gravity (distilled water = 1) 1·0006 *elettricità bianca*, 1·0002 *elettricità verde*, 1·0002 *elettricità rossa*; solid matter in 100 parts, 0·01 *elettricità bianca*, 0·01 *elettricità verde*, 0·01 *elettricità rossa*. The microscope showed an absence of any floating particles or sediments such as are usually present in vegetable extracts. There is but one substance which possesses all the above qualities, that is water. None of these fluids differ at all from water in any of their properties." So far the analysis seems to have been conducted in a reasonable manner, but when we come to the electrical investigation we find as gross an ignorance of elementary electrical laws displayed as can well be imagined. Mr. Stokes writes:—"To find if they possessed any special electrical properties, they were placed singly in thin glass tubes; these tubes were suspended by silk filaments. Under such circumstances an electrical body would point one end to the north and the other end to the south. Not one of these came to rest in such a position; neither were any of them attracted by a magnet, as an electrical body would be. Hence, they certainly are not electrical." Comment is needless. Mr. Stokes should be at once secured by Mr. C. B. Harness.

---

Something out of  
Nothing.

"NOTICE is given of the closing of the transfer books of Elmore's Foreign and Colonial Patent Copper Depositing Company for the purpose of paying a dividend." So say the newspapers. This dividend must, of course, be out of the floating of sub-companies. What too strong can be said of this whole business of floating company

after company without having once proved the intrinsic value of the Elmore process? Only company promotion and dividends therefrom support the fiction, but none the less evil will be the day when all the facts connected with the process and its present handling are known, and they cease to tempt either the ignorant investor or him who hunts for premiums.

The Loss of the  
*Serpent*.

THE excuses, or reasons, given for the loss of H.M.S. *Serpent*, such as the effect on the compasses produced by the vicinity of large quantities of iron ore on land, the "humbugging" of the compasses owing to the magnetism of the hull being affected by the buffeting of the waves, and the ship's course being thrown out by a strong current, savour of too much protest on the part of those in authority. Thousands of merchant steamers are continually passing Finisterre, and unless a merchant captain had some better excuse to give than either of the above for the loss of his ship, his certificate would be in considerable jeopardy.

Another Subway  
Explosion.

ON Wednesday afternoon, last week, another alarming occurrence took place in connection with electric lighting in Newcastle, at the corner of Pilgrim Street, New Bridge Street and Northumberland Street. A few days ago, it will be remembered, the cover of an electric light junction box in the pavement blew off in that neighbourhood. On Wednesday afternoon, a puff of smoke was observed to issue from the same box-cover. Nothing further happened to this box, but the covers of two other boxes in the locality almost immediately blew off. Fortunately, at the time of the occurrence, comparatively few persons were about, and no one was injured. The utmost alarm, however, was felt by the residents in the locality owing, as stated, to a similar accident having occurred so short a time ago. The opinion expressed by the workmen is that the explosion had been caused through an escape of gas. Writing to us on this topic Mr. Arthur E. Gilbert makes the following comment:—"Surely my system of ventilation, which you illustrated some months ago, would obviate these serious explosions. No ventilation appears to be provided for, or even considered essential, but for safety I think you will say it is essential."

Some Experiments  
in Electrolysis.

IN a recent issue of *The Chemical News*, Mr. P. L. Aslanoglon describes some rather empirical experiments which he has conducted on the electrolysis of various substances. He passed the current from six Fuller's mercury bichromate elements through various solutions and obtained the following results:—Water containing calcium, magnesium, barium, strontium, or zinc hydrogen carbonate yielded, when the current was passed, a deposit of the normal carbonate of the metal at the negative electrode, and at the same time both oxygen and hydrogen gases were evolved. There was the same evolution of gases when the current was passed through a solution of ferrous carbonate, but the carbonate remained unchanged: there was no deposit. A solution of silver chloride in aqueous sodium thiosulphate, yielded under similar treatment a deposit of metallic silver: hydrogen was evolved, but no oxygen. In this case an odour of sulphuretted hydrogen was observed. When lead sulphate dissolved in ammonium tartrate

was subjected to the same treatment, a black substance was deposited at the negative pole: it gave off an ammoniacal odour. The positive pole and the liquid became yellow, and there was an evolution of oxygen and hydrogen gases. It is a pity Mr. Aslanoglon's work has not been quantitative. We need hardly point out how much more valuable such researches are, and it is to be hoped that the experiments will be repeated with solutions of known strength, and that in each case the resulting substances will be carefully analysed.

Electricity.

THE new journal has appeared, and we notice an error in the second sentence. "Fifteen years ago," says the editor, "a paper exclusively devoted to electrical matters would have had no *raison d'être*," and yet the ELECTRICAL REVIEW has been steadily making its way since the year 1872. The candid admission, too, that it is not intended to supersede any of the existing papers is welcome news, and once again we wish our penny contemporary a flourishing future.

Electricity.  
Daily.

THE *Elektricitäts-Zeitung*, of Berlin, a bi-weekly journal of fifteen issues, is now announced to appear three times a week. The editor is Arthur Wilke, and the hope is expressed that in the near future the paper may appear every day on the breakfast table of those people interested in electro-technics, in common with their other daily periodicals.

Fire at Grosvenor  
Gallery Station.

ON Saturday last the Grosvenor Gallery Central Station, belonging to the London Electric Supply Corporation, was destroyed by fire. The place was left in charge of a linesman, who, while endeavouring to switch off a converter, failed to firmly fix the plug between the two terminals, which caused an arc to form. The details of the mishap, which in less than an hour's time left the station completely gutted, are given in another column, but doubtless the fear of getting a shock from a current of 5,000 volts pressure, even if such a thing were impossible, was the cause of the man's loss of nerve. The instruments and converters were destroyed, business for the present being entirely suspended, and, will it be credited, the loss is not covered by insurance. Coming to the cause attributed in the foregoing remarks, there appears to have been some laxity in a method of management which leaves an inexperienced man in such a responsible position, for inexperience and responsibility are shown by the results. Grave censure is without doubt due somewhere, but one could not for a moment cast blame upon a man who is actually admitted to be new to the work. We are afraid customers who may have been entirely dependent on the supply of current for light may not take a too favourable view of the accident. It must not be thought, however, that we fail to appreciate the many difficulties and troublous times through which the company has passed, and this crowning disaster, coming as it has just when the Deptford Station seemed to promise to keep up the complete supply for the company's system, is doubly disheartening, and we sincerely sympathise with Mr. Ferranti and his supporters, and express the hope that they may soon tide over their ill-luck.

## GENERAL INSTRUCTIONS FOR OVERHEAD LINE CONSTRUCTION FOR ELECTRIC RAILWAYS.

THE large amount of overhead railway work now in course of construction, and the large number of roads which will undoubtedly be constructed in the future, makes it desirable to have some clearly defined rules for the construction of overhead work, as well as that relating to the ground conductor. Our readers (*New York Electrical Engineer*) will therefore be interested in the admirable general instructions relating to this part of railway work, which have been issued by the Westinghouse Electric and Manufacturing Company, and which, if carried out faithfully, cannot fail to result in a substantial and lasting conductor system, with the least possible annoyance to the public.

**Franchises, Permits, &c.**—The owners of the railway must secure all necessary franchises and permits from public authorities, or private individuals, for properly carrying on the work of construction, including permission to set poles in the most advantageous positions, and to run guys where necessary. They shall also do all necessary removal or trimming of trees, and shall be responsible for all necessary removal of existing wires or poles or other impediments.

**Contractors.**—The contractors shall comply strictly with the local laws governing their work, and are responsible for all unlawful damage done by their employes in the progress of their work. They are required to do all the carting and storing of material, to furnish all horses, waggons, men and material for carrying on work.

**Completion of Work.**—Each branch of the work must be pushed rapidly to completion as taken up, all re-sodding, paving, &c., promptly done, and all debris and material removed. All breakdowns, or deteriorations of the work, which shall occur before the final completion and acceptance of the whole, shall be repaired and made good by the contractors at their own expense.

**Inspection and Acceptance of Work.**—The Electric Company may appoint an inspector, who shall have authority to decide and direct how every branch of the work shall be done, and what material shall be used. He may at any time order such changes and removals as he may see fit. If the inspector orders any work done or materials used which are not properly included in, or covered by, the contract, he shall give a written order to the contractors, specifying, as nearly as possible, the amount of labour and material involved. The inspector will give a written acceptance to the contractors when he considers their work properly completed.

### TRACK AND GROUND CONNECTIONS.

On all roads where the size and material of the continuous ground wire are not particularly specified, No. 0 B. and S. galvanised iron wire shall be used. All joints in it shall be soldered. It shall be stretched taut, and secured to cross-ties or stringers with galvanized staples. It must be so deep in the ground that it cannot be reached by wheels, &c. It must be run close to one rail, and connected to each rail bond it passes by a wrapped soldered joint. Every 150 feet a branch of No. 0 B. and S. wire shall be soldered to the continuous ground wire and to a rail bond on the other side of the track. Where there is a double track, there must be a cross wire every 150 feet, which is soldered to bonds on ground wire on all four lines of rail, and is the only cross connection required. It must be of No. 0 B. and S. (See fig. 1.)

Between the ends of all consecutive rails, of whatever form, a rail bond, the Electric Company's standard pattern, shall be used. This bond is shown in fig. 1. The holes in brass or copper block must be bored to fit rivet and wire, not punched. The end of wire must be put through block, and upset so that it cannot pull out, and the whole bond must be covered with half-and-half solder. The rivet must be Norway iron,  $\frac{1}{8}$  inch

in diameter, and of just sufficient length to pass through flange or web of rail and be riveted.

The best place for rivet holes in different kinds of rails depends to a great extent on paving and other conditions. The rivet must always pass through the rail, and be upset into a counter-sinking at the end of hole. No part of the bond must be exposed or placed in such a manner that it can be touched by wheels or that the movements of the rail will tend to break the wire. The admissible positions for rail bond rivets in girder, T and tram rails are shown (fig. 2). No rail bond may be less than 10 inches in length, and the bonds must be slack when in place, but as short as the conditions will permit. Where short pieces or castings, such as switches, frogs, or curve castings, occur in track, the pieces must be connected up in the same manner as consecutive rails, and each bond soldered to the continuous ground wire.

In steam railway crossings, each piece of rail must be connected to the continuous ground wire. Where a draw bridge is crossed the rails on either side should be connected by a No. 0 B. and S. copper wire, weighted to the bottom of water, with such connection as is necessary for rails on draw.

Cables or wire leading from rails to dynamos must be soldered to continuous ground wires and bonds on all lines of rails, and must be connected to the positive terminal of dynamos. When ground feeders are run, they must be insulated in the same way as line feeders, but must, if possible, not be run on the same line of poles, and in no case must they be run on the same insulated pole tops.

### POLES.

**Wooden Poles.**—Must be 30 feet long, and, for use on straight lines must not be less than 7 or more than 8 inches in diameter at top when finished, and they must not be less than 10 inches in diameter 5 feet from the butt. They must be of sound chestnut, cedar or Georgia pine, may be sawed or natural round, but in both cases must be dressed smooth and coned at top, cones having two coats of paint.

**Poles for Corners.**—At curves, and for the ends of line, or which in any way bear part of the pull of the trolley or feed wires, must be not less than 8 inches in diameter at top and not less than 12 inches at a point 5 feet from the butt. All poles must be straight and uniform and free from shakes, checks or large knots.

**Iron or Steel Poles.**—Of whatever form shall be of a strength and stiffness at least equal to the wooden poles specified. A pole made of three sections of extra heavy pipe, top section 3-inch pipe 5 feet long; middle section 4-inch pipe 6 feet long, and bottom 5-inch pipe 16 feet long (these lengths do not include the lap in joints), is sufficient for light work. All joints must be made perfectly rigid and as strong as the adjoining pipe, with proper provisions against telescoping.

All iron poles must have a thoroughly insulated iron top, to which wires are secured. This should be mounted in a hard-wood plug in pole top, boiled in paraffin. The top must protect the plug entirely from water; it must have a deep petticoat extending at least 1 inch below pole top, and standing at least 1 inch clear of it on all sides. This top must be fitted with fixtures for securing span wires and insulators for feed wires, &c.

**For Curves.**—Angles of feed wire, and ends of line, &c., extra strong poles must be used. There is nothing in the work of building a line so essential to its durability and good working as is the perfect rigidity of corner poles. The top section of curve poles should in no case be less than 5-inch extra heavy pipe, and, of course, special insulated tops must be provided for them. Corner poles must be fitted with strong eyebolts below the wooden plug for fastening guys.

**Pole Setting.**—All poles on straight line work shall be set 6 feet in the ground. Large stones shall be tamped hard against butt of pole on side away from rails. Where practicable, pole should bear at surface of ground against curb stone, or have the space between it

and curb stone filled by another stone or stones. Where there is no curb stone, a timber not less than 4 x 8 inches and 3 feet long shall be laid against the rail side of pole, 6 inches below the surface of the ground. A large stone, at least 2 feet long and 1 foot

diameter, and filled with concrete, which should be given ample time to set before any strain is put on it. Poles of wood or iron for straight line work should have about 3 per cent. of rake away from street. (Fig. 3.) Wherever possible, the line of the tops of poles

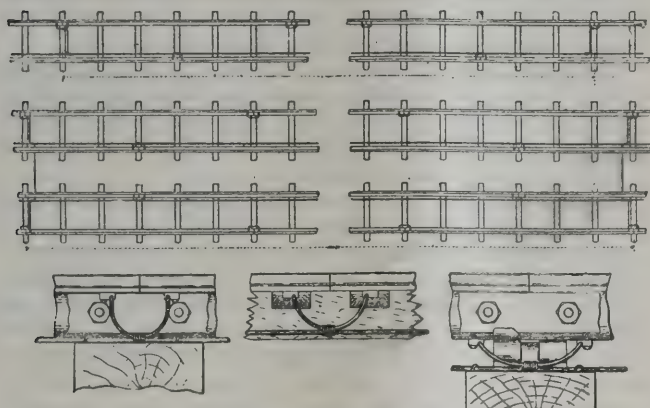

FIG. 1.—METHOD OF CONNECTING GROUND WIRE, SINGLE AND DOUBLE TRACK.

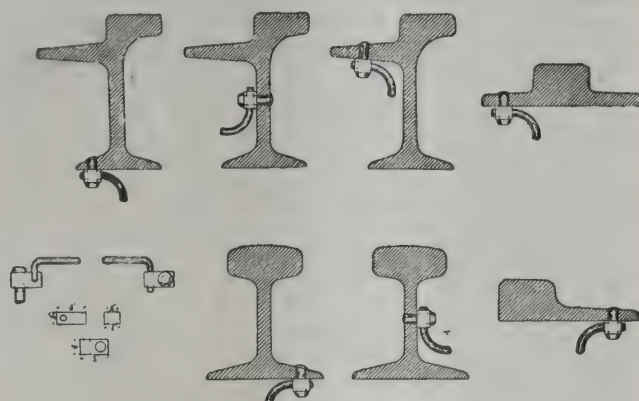

FIG. 2.—METHOD OF CONNECTING GROUND WIRE TO RAIL.

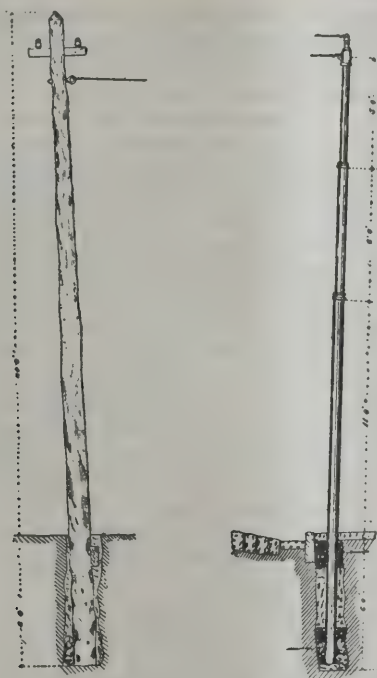

FIG. 3.—METHOD OF PLANTING WOOD POLE AND IRON POLE.

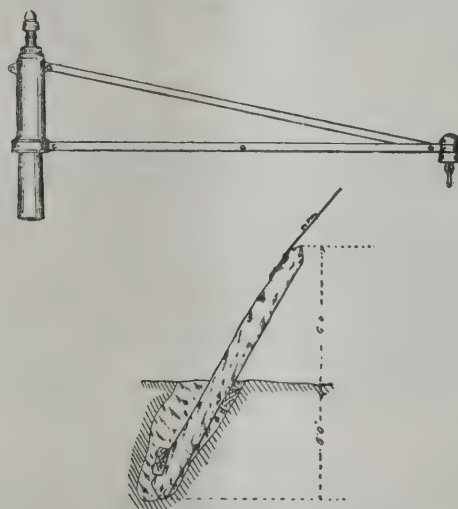

FIG. 4.—GUY STUB AND OUTRIGGER.

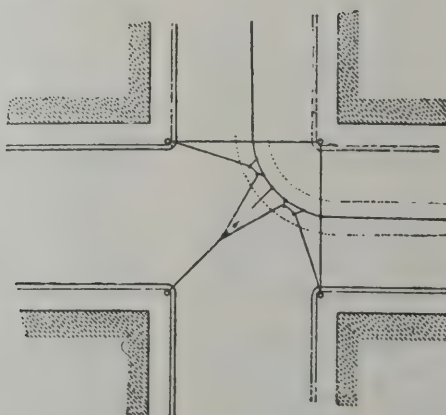

FIG. 5.—METHOD OF CONSTRUCTING OVERHEAD CURVE.

wide, should be used in place of timber when practicable. All poles shall be tamped solidly. (Fig. 3.)

In setting iron poles, good cement concrete must be used. The quality of the concrete should in all cases be good at the top and bottom of holes, and large stones may be used at these points to advantage. The hole in which an iron pole is set should be at least 20 inches in

should be at a uniform height from rails, and the ground around poles should be graded to give the pole the proper depth of setting.

Poles which support part of the strain of curves or bends of trolley or feed wires must, in all cases where it is possible, be thoroughly head guyed. When this can be properly done, no extra precautions need be

taken in setting, and poles should be set nearly vertical. The same applies to poles which support ends of lines.

Guy stubs must be anchored 5 feet in ground, and their tops must be 6 feet above ground; the stubs must be at least 8 inches in diameter, and must rake well towards pole top or point directly towards it. Guys must make no metallic contact with insulated pole tops or with any other wires which lead from the pole. Guys must be made of twisted (doubled) No. 6 galvanized wire or something equally strong and durable. (Fig. 4.) When guys cannot be used on the poles above-mentioned, they must be set 7 feet deep in a hole 30 inches in diameter, and built in solid with stone and concrete. Poles shall not be more than 125 feet apart, except where a greater distance is unavoidable.

In all cases where the character of the soil or the nature of the strains make the ordinary method of setting poles inadequate, precautions must be taken to make poles sufficiently firm, and whenever poles yield under the strain put upon them, the Electric Company's inspector may have them reset at the contractor's expense. This may also be done when poles are displaced by undue strains imposed by contractors in building line, &c.

When the poles are not set by contractors who put up the wires, the latter must assume responsibility for the rigidity of curve and terminal poles, and their work can in no case be made acceptable unless these poles are thoroughly strong and firm or properly guyed.

#### FIXTURES.

All insulator pins and pin brackets shall be of the best oak or locust. Pin brackets shall be secured to pole with one 5-inch and one 7-inch lag screw.

*Cross Arms.*—Shall be of the best pine,  $3\frac{3}{4} \times 4\frac{1}{2}$  inches, painted with two coats of Indian red. They must be secured in perfectly fitted gains with two 7-inch lag screws. Insulators must be extra heavy, such as are made for the largest sizes of wire. Where sharp turns are made with heavy wires, two or four cross arms must be used, and, where necessary, iron pins and large paraffined wooden insulators may be used.

#### WIRE CONSTRUCTION.

*Span Wires.*—Are to be of stranded wire,  $\frac{5}{16}$ th inch in diameter, made of seven wires without a core. They must be secured to eye-bolts, which pass through pole, and have a nut on the opposite side. These bolts to be of  $\frac{1}{2}$ -inch galvanized iron. With iron pole a suitable eye must be provided for span wire. The height of eye-bolts from the rail must be uniform on streets of equal width, and must be such as to hold the trolley wire at a height of 19 feet from the ground. A span wire must be allowed to sag about 3 per cent. of its length. When first put up, span wires must be left with one temporary connection, and must be carefully pulled up to uniform angle after trolley wire is run. They must in no case be connected so that slack cannot be readily taken in.

Span wires proper are only to be used where the line is perfectly straight. Where there is any lateral strain on trolley wire, double pull-off brackets must be used, with wires of the same material as span wires, leading to opposite sides of street.

*Trolley Wire.*—Must be put up in as long lengths as can conveniently be handled. The ends must be secured to a long V made of double  $\frac{5}{16}$ th stranded wire, and led from securely guyed poles. It must be connected to this V by an insulator of suitable strength. Trolley wire must be drawn to a moderate tension only, allowing about 18 inches of sag in 125 feet. In hot weather it should be drawn slightly tighter. It must be run off large reels, on which it is carefully wound; it must not be bent, kinked, or scratched. The practice of temporarily securing long lengths of trolley wire, and allowing by guess work for each curve is not approved, as it is sure to cause inequalities of tension in line or improper position of curves. Curves should either be completed as they are reached by the trolley wire, or

should be built successively after the wire is up, an ample amount of slack being provided and carried ahead as the curves are completed, the line being permanently drawn to the proper tension, and bridled as each is reached.

The hanging line insulators which support the trolley wire shall be clamped on (not soldered) after the line is accurately in place, and all curves completed.

Joints in trolley wire shall be made in suitable brass tubes, with tapered sides; they must be soldered by pouring, must be wiped smooth, and must bear a strain equal to the strength of the wire itself. Joints shall not occur in or near curves.

*Construction of Curves.*—The positions of poles near curves should be carefully selected, and the poles must be permanently guyed, or otherwise properly strengthened, before work of running trolley wire begins. At the beginning and end of each curve the line must be bridled to the corner pole, and one on the opposite side of the street. The fixtures for these bridles serve as the first and last pull-off brackets. They must be carefully swetted to the wire. Not more than five pull-off brackets should be used between these bridle fixtures on a 90 per cent. curve, except where the curve is very long.

*Pull-off Brackets.*—The pull-off brackets shall be at equal intervals and soldered to the wire. They must be so placed that the trolley is exactly in line with the wire as it passes them. To accomplish this, the bracket must be more or less inside of line vertically over the centre of the track, the height of the wire, and the radius of the curve determining the position.

Pull-off wires shall be of the same material specified for span wires. They may be secured either directly to eye-bolt on pole or to a stout galvanized iron ring at a suitable distance from pole. On double curves, &c., insulators shall be used only on wires which run to poles. Where short wires are used to connect pull-off brackets (for instance, those which lead to the brackets on the inner curve) no insulators shall be used.

The weight of curves must be supported by double pull-off brackets, with wires leading to opposite side of street. Fig. 5 shows a sample curve. On all curve construction the greatest neatness and strength will be insisted on; the minimum possible number of wires and insulators must be used; the angling of wires must be advantageous; every wire must be made to serve as many purposes as possible.

Switches, crossings, circuit breakers, lightning arresters, &c., &c., shall be used when and in the manner specially directed.

*All Material and Fixtures.*—For line work shall be of the form supplied or specified by the Electric Company. All joints and connections in insulated wires shall be covered with three layers of the best weather-proof tape. All ungalvanized iron work and wooden insulators shall be thoroughly and neatly painted with P. and B. paint. Joints in feed wire must be of a neat, strong and approved form, thoroughly soldered. No telegraph joints will be allowed in wires larger than No. 0 B. & S.

*Feed Wires.*—These must be put up to gauge specified, and must be 97 per cent. of the conductivity of pure copper. They must be put up without kinks or injury to the insulation, and in lengths of not less than 500 feet. Feed wires must be led into the power station through suitable rubber or porcelain insulators. Every connection to the trolley wire must be made through one of the span wires, which must be fitted with an insulator at each end, and connected to the feed wire by an insulated jumper of No. 6 B. and S. wire, soldered to both. Connection to the trolley wire must be made by an insulated hanger, similar in appearance to the regular insulators. These span feed wires must be of the same material as regular span wires, but covered with the best weather-proof insulation. Where feed wires have to be led under water, the best armoured cables must be used, and suitable terminal fixtures.

*Guard Wires.*—Wherever there is great danger of crosses with telephone, telegraph or other wires, through their falling on the trolley wire, guard wires must be

used. They must be of No. 8 B. and S. galvanized iron wire, and must be hung to span wire of the same material as the ordinary span wires. Guard wire must be 18 inches or more above the trolley wire. They must be insulated from the span wires, and the span wires must be insulated from the pole tops. Porcelain insulators may be used, but must have no sharp edges.

On single track work, guard wires must be 4 feet apart, with the trolley wire midway between them. On double track work, three wires will be used, one 2 feet outside of each trolley wire and one in the centre. Guard wires should not be used except where the need for them is very positive, and where their construction can be made simple and effective. A complication of guard wires will always be a source of trouble.

*Outriggers.*—When the trolley wire is hung to outriggers instead of span wires, the insulators must be so constructed that they will bear the lateral strain from the wire where the line is not straight. The outrigger arm must be insulated from the pole when the latter is of iron. (See fig. 4.)

### THE ALTERNATING CURRENT TRANSFORMER SYSTEM IN SOUTH AMERICA.

[FROM A CORRESPONDENT.]

UNDER this title I have some months ago sent you a report on the extension of the above systems in the towns of La Plata and in Brazil. To this report I am now in a position to add some further particulars.

The *Companhia Luz Electrica*, in San Paulo, which, as I informed you, has undertaken the lighting of San Paula and Casa Branca, and has there erected central stations on the alternating current transformer system, has, in the meantime, extended its sphere of activity and its capital. It has undertaken the supply of water, enlarged its capital to five million francs, and has been re-constituted under the title "Companhia Aqua e Luz do Estado de San Paulo."

Above all, the new company has undertaken the extension of the central station at San Paulo, and is erecting an alternating current machine of the type  $A_3$  (for 50,000 watts), with the requisite motor.

The company has further concluded an agreement with the municipality of Ouritzba (the capital of the province Parana), and is bound to get the public lighting there in action by June, 1891, at latest.

At the distance of about 4 kilometres from the town there is water power, which has been taken into consideration as supplying the needful force for the installation to be erected. But at present, owing to torrents of rain, the annual flow of water in the river cannot be ascertained, nor the amount of water-power which will be available. Hence, in the first place, two alternating current machines of the type  $A_3$ , for 30,000 watts each, are being erected with two Steinmüller tube boilers and two steam engines by Tangyes, Limited, so that the electrical works will be driven by steam power during the first period. The central station will be erected close to the railway terminus, so that a supply of fuel may be obtained cheaply.

If on further investigation it is found that the project of using water-power can be carried out, a definite conclusion will be come to as to whether the works will be conducted further with steam-power, or remodelled to suit hydraulic power. After the decision of this question, the extension of the works will be taken in hand, so that the demand for private electric lighting in Ouritzba can be duly met.

The computation of the price of the electric light will be carried out according to agreement with the Municipality, after working for a year on the scale of 4,000 candles. The calculation for private lighting will be made after the works have been definitely completed.

### THE ELECTRIC LIGHTING OF BRUSSELS.

THE question of the electric light remains open at Brussels, says the *Independence*. The technical departments of the communal administration are studying the different propositions made to the city authorities, and the College and Council will shortly be called upon to give their opinion upon the various tenders. This decision will be grave and difficult. Among the specialists themselves the different systems are keenly discussed, the advantages of each being contested; and it must be recognised that the problem, of which it is easy to claim an immediate solution at a meeting, is singularly complicated. As to Brussels, the situation is rendered still more difficult by the private stations erected at different points, and each of them monopolising the lighting of an area naturally chosen under the most favourable conditions.

In a new study on this subject, M. Ch. Haubtmann declares himself in favour of a single station outside the agglomeration. He is certain that electricity, in addition to its qualities of hygiene and safety, is before everything the lighting *de luxe par excellence*, and if to-day its upward rise is somewhat hindered on account of its relatively high price, the day on which it adds cheapness to its numerous other advantages over gas it will take possession, as gas formerly did, of the most modest dwellings. This cheapness, it may be said, is in the hands alone of the engineer electricians charged with establishing central stations of electricity, and it is by having acquired that idea, that several large installations have been made abroad under economical conditions which are truly remarkable. To induce machinery to output to its maximum extent appears to be the domain of the engineers; but what the electrician must specially seek is to establish a system capable of successfully rivalling that which is already installed. We believe that, for the time at least, we must not reckon on obtaining a better yield from the dynamos than that which we have to-day, but we should exclusively limit ourselves to keeping down to their lowest extent the expenses of installing and the working of the stations, as well as the loss arising from the energy absorbed by the conductors, &c.

This programme, on account of the tolerance which municipal authorities grant to the companies tendering for the lighting, is occasionally easy to carry out. Thus, in America, besides the facilities which are given to these companies of erecting their stations in the centre itself of the sector which they are to supply, that is to say, most often in the centre of the town, no difficulty is raised as to their establishment of aerial conductors. It can easily be imagined that, under these conditions, if coal be cheap enough, the electric light can advantageously compete with gas. But if, on the contrary, as in England, and in London particularly, central stations in the interior of the city are not tolerated, nor aerial cables, the problem becomes singularly complicated, and presents great difficulties.

As to Paris, at first, electrical stations were allowed to be established in the centres of the quarters, but a report of M. Lépine, secretary to the Prefecture of Police, recommends their transfer beyond the walls of the *enciente*. An important city seeks to get rid of the vibration caused by the steam engine at night, which incommodes the neighbourhood of the central stations; without reckoning this, despite all the smoke consumers with which the furnaces are provided, they allow sufficient carbon oxide to escape to reveal to the least inexperienced person the presence of a central electricity station. In short, the problem of electric lighting in large cities may be thus formulated under most general conditions:—to have a station outside the city, and underground cables conducting the electricity to the sector, at a net price capable of competing with gas. This is not impossible now, for the establishment of the station in a place isolated from buildings, in proximity to the means of transport, will procure a real saving in working, and may be, in building over that installed in the centre of the city itself. In this case,

the type of boiler which appeared the most economical could be employed without having to take police ordinances into consideration; the furnaces could be placed in such a manner as to suppress troubles regarding fuel; and, in most cases, there would be cheap water, &c. Regarding steam engines, being no longer bound by the position, the types giving the best results could be adopted, and several reserve engines could also be kept. In a word, a number of advantages would be enjoyed which it is impossible to get in the centre of towns and cities; among others, water and fuel at lower net prices, and apparatus giving a maximum of yield.

An outside station will doubtless cost, in establishment expenses, as much as an urban station, because, in the first place, a larger one will be built, and more apparatus will be placed therein, than if it were in the city. On both sides there will be the same building expenses, but there will be more economical production in the case of the station outside the section. There is then a first advantage resulting from conditions imposed by cities; let us say at once that it is compensated by an inconvenience much more important, more especially as regards the value of the system of the company's working. We refer to the loss arising from the transport of energy, which is obliged to be carried on account of the distance of the place of production from the place of consumption, and the expenses of the first establishment of the conductors. The labours of Cabanellas, and some experiments of M. Marcel Deprez, have taught us how to get rid of the major part of this inconvenience by employing high tensions, so that, all allowance being made, an electrical station situated far from the city will be found in an excellent position to compete with gas and the existing urban stations, while admitting that these latter are still tolerated.

We have already had an opportunity of pointing out, when the lectures were given at the beginning of the year before the Belgian Engineers' and Industrials' Society, the great difference existing between continuous currents and alternating currents as regards safety. There remain to be examined to what exigencies should a central station be able to respond before furnishing light and energy. For that, it is sufficient to pass in review what the subscribers to an electricity company have a right to expect from it:—1. To be able at any hour of the day or night to light the required number of lamps, or take the energy which is necessary. 2. To enjoy a light at least as regular as gas; that is to say, without variation in luminous intensity. 3. Not to be at the mercy of a bad installation and canalisation, in understanding by that never being deprived of light, on account of accidents to apparatus, earth contacts, &c. 4. To have no chance of accidents or electric shocks, dangers from fire, &c. 5. To realise as much as possible a saving on the former system of lighting. These five subscribers' conditions are reduced to two for the concessionary company:—1. To possess a central works producing economically and a system of distribution absorbing scarcely anything. 2. To have a reserve system capable of meeting all eventualities, consisting either of accumulators or spare dynamos, according to circumstances.

For a central station, this security consists simply in furnishing, at any moment of the day, the quantity of energy required by the section which it supplies. From this point of view, a station should be able to pass easily from a maximum output to rest and *vice versa*, and that very rapidly, instantaneously even, if that be possible. For this there are two solutions: To employ batteries of accumulators ensuring the service without the aid of the dynamos for a certain time, or to have dynamos constantly ready to work. In adopting the system with secondary batteries, if the installation is large and situated at a distance from the section, the employment of high potentials becomes necessary; then, in place of having accumulators in the central works themselves, they can be spread over different parts of the line, so as not to be obliged to adopt too large batteries in tension. These accumulators will bring about the disappearance of one of the greatest

inconveniences of lighting workings which operate during a short period of the day only, thus giving a bad utilisation of the dynamo.

We will not here enter into the technical details of the installation. We will only mention in conclusion a point which is much contested—the question of the strength of the units of production, on which many engineers seem divided. Should the producing stock be divided as much as possible? Or, on the contrary, should we lay ourselves open to make large dynamos? Each of the two schemes having its good features, we think it wise to adopt a medium course. The small units have the advantage, in case of injury, of rendering useless only a small portion of the total producing power, but they require more room, necessitate greater watchfulness, and cost more for working expenses than larger ones. The larger units, if they remain for a short time out of working, cause a loss, by the interest of the capital which they represent, of the profit which is realised on them by overlooking, yield, &c.; but we believe we are able to say that in dynamos, which are but little susceptible to derangement, powers may be attained which prudence would blame if steam engines were in question. It remains to be known whether these dynamos will always work at full load, for it is evident that an apparatus producing below its nominal power works under very bad conditions of yield.

The system of working must, then, be established under such conditions that the dynamos may always work with their maximum of production. For this it suffices to divide the apparatus supplying the total energy into two groups—a group of small units, having a total power, spread over five or six apparatus, equal to the nominal power of one of the dynamos of the other group, composed wholly of large units. It will be immediately seen that with this system of working a large dynamo only works as much as is necessary to produce a similar result to that for which it has been established, and that in proportion as the work demanded increases, one or several of the small dynamos are introduced up to their total energy, a value for which they are withdrawn by again introducing a large unit. This process gives a maximum of yield from the apparatus, and necessitates but few supplementary establishment expenses.

## THE EVOLUTION OF THE MICROPHONE.

By A. M. TANNER.

THE object of the present paper is to demonstrate that the microphone did not spring into existence Minerva like, but was the production of a slow growth continuing through several decades; it has several prototypes as will be shown further on. In former articles, which appeared in the ELECTRICAL REVIEW, I drew attention to the fact that certain types of Trevelyan instruments, possessing carbon rockers and bearers, will, under certain conditions, serve as microphones, the most essential condition of course being that the rocking electrode should be made sufficiently light to be affected by ordinary sound waves. The instruments reviewed in the present article do not require a change of form or diminution of weight, but will at once serve as microphones or telephones, having variable contact current tension regulators. In the outset, in order to remove any doubt that may exist as to who first discovered the principle of varying the resistance in a galvanic circuit by electrodes of metal or other material resting in loose contact, one upon the other, and serving to change the tension of the current flowing across said electrodes, not by a mechanically applied pressure, but automatically by a mere change of position or difference of contact between the electrodes, it is necessary to refer to the *Comptes Rendus* of the French Academy of Sciences for 1878, page 131, where Count Du Moncel states that it was not until the year 1856 that he discovered the change of electrical resistance produced by

imperfect contact electrodes. This, of course, determines the date of Du Moncel's discovery, and in view of what follows, it is necessary to award the credit of prior discovery to Prof. Albert Mousson (just deceased at the age of 86 years), of Zurich. In the *Nouveaux Memoires de la Société Helvétique des Sciences Naturelles* for 1855, Vol. XIV., appears a lengthy paper of Prof. Mousson on the changes of the galvanic resistance of metals. Among other experiments, mention is made of the variable resistance between springs rubbing upon discs, just as in the electro-magnetic circuit breakers of Du Moncel, when he discovered that a light or strong contact between the contact spring and collector disc will produce a variable resistance.

In fig. 8 of the plate accompanying Mousson's article, he illustrates an experiment with two crossed

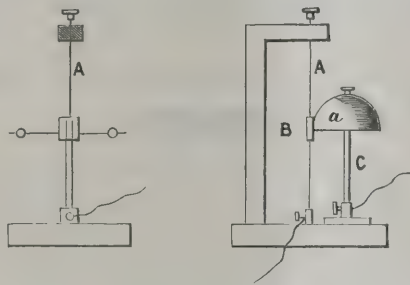

wires, and he adds that in a loose contact *without pressure*, as when two solid wires are placed one upon the other, the resistance is variable because of the changes of position, or changes of temperature at the contact points. The change of position of the loose contact electrodes is produced by the action of the current itself.

In the *Compte-Rendu* of the 45th session of the Société Suisse des Sciences Naturelles-Lausanne, 1861, is a communication from Prof. Mousson "on the movements that present themselves in a galvanic circuit at the points where the conductors touch each other very lightly." Mousson here describes the experiments of De la Rive in 1845, Rollman and Page in 1850, and Gore and Forbes in 1858, and says that they operated with rolling and rocking bodies.\* Mousson in describing his own experiments, says that for a "rocker" he selects a bar analogous to that employed in the Trevelyan experiment only *very much lighter*, and resting upon two knife edges brought close together, set in motion, while the current traverses the point of contact a sound is produced which results from the rocking of the bar on the two knife edges (bearers) and which continues as long as the current passes. Mousson adds that the movement of the "rocker" does not commence by itself, but must be started by an external cause, although sometimes an *imperceptible trembling of a table serves to set it in motion*. In order to better study the conditions of the movements produced by parts of a galvanic circuit in loose contact, Mousson employed an instrument by means of which the pressure of the contact could be varied. The "restoring force which in the rocking bar is its weight" is here replaced by the "torsional elasticity of a metal wire secured at its lower end and stretched by means of a screw at its upper end. A small plate fixed at the middle of the length of the wire carries two platinum knife edges, which run parallel to the wire, and are brought close together and bear upon a clock bell (small gong). The current passes to the gong through the wire and contact points, and the tension of the spring and the pressure are easily regulated in order to produce continuous vibrations, which acquire considerable force if they are in accordance with one of the sounds of the gong." Mousson here describes the results which follow when the pressure between the contact points is varied. He says that when the pressure is at zero the mechanical and galvanic contact is interrupted, no current passes, and the needle of the galvanometer does not move. When a slight pressure is applied a mechanical con-

tact takes place, but the galvanometer needle still remains at rest, because the galvanic contact is not yet established. This curious fact can no doubt be attributed to the *presence of a layer of condensed air*, which exists on the surface of all solid bodies, and which by resisting a slight pressure prevents metallic contact. When a greater pressure is applied it causes a mechanical and galvanic contact, but *it is always inconstant*. The needle oscillates constantly with greater or less force and is never in a state of repose. At the same time a slight hissing is heard like the long-continued sound of the consonant s. The current passes, but it constantly modifies the contact and the resistance presented by the same. Mousson attributes the change of resistance to calorific effects at the contact points, and says that the "variations of contact are produced without interruption of the current."

An illustration of Prof. Mousson's instrument as above described, is found in his work "Die Physik auf Grundlaye der Erfahrung," Zurich, 1874, vol. 3, page 412, fig. 942. The article relating to "movements produced by parts in light contact," describes the instrument as follows, viz., "The torsional elasticity of a strong wire, A, as shown in fig. 942, serves to hold contacts together. The wire is provided at the middle with an arm, B, clamped to the wire, and provided with two knife edges of platinum, which latter are held against a harmonic bell, C, conforming to the vibrations of the wire. When the current enters the bell at *a*, and passes out through the bell shank, light vibrations are caused by the agitation of the lever, which are reinforced by the bell, and are heard as a clear tone of considerable loudness.

I think it is almost needless to add that Prof. Mousson's instrument, as above described and illustrated, becomes a veritable microphone when "spoken to," and will transmit speech when used in connection with a telephone receiver. To show how carefully he studied the phenomena that are supposed to take place at variable contact electrodes, it is only necessary to say that Mr. Berliner, and others, have attributed the action of the microphone to the action of a "layer of condensed gas between the electrodes." Mousson, it will be seen, makes mention of this phenomenon. Then, again, transmitting-telephones have been constructed where the electrodes are held in contact by a torsion spring, very much as in the Mousson instrument.

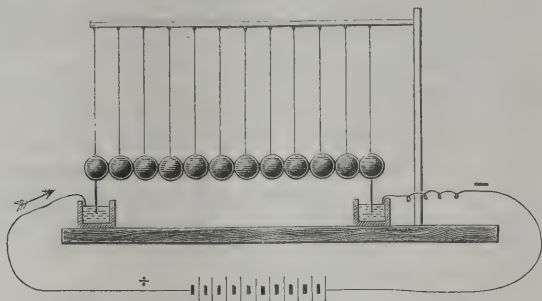

I now call attention to other references which disclose instruments that have a close bearing upon certain special types of microphones. It is undoubtedly well-known to those conversant with the history of the microphone, as disclosed by text-books, that the microphone of Boudet de Paris has a series of carbon balls placed in a glass tube, and which operate by impact, as "in the billiard ball experiment."

The French journal *Cosmos*, for 1858, vol. xiii., p. 148, has an article by Van Breda and Lorgeman intended to prove Ampère's law of repulsion. They state that "in carrying out their experiment they employed 12 iron balls, of some 8 to 9 millimetres in diameter, suspended as the billiard balls in the experiment on the impact of bodies, the centres of the ball being in line with each other. The two end balls have points which dip into mercury cups that are in communication with the poles of a battery of 12 Grove elements. When the current is made to traverse the balls the two end balls are repelled

\* These experiments and others were described in my previous articles.

from the others about one millimetre, and sparks are observed between each pair of balls."

Wiedemann, in his work "Die Lehre der Electricität," in referring to this last described experiment, which may be illustrated by the accompanying sketch,

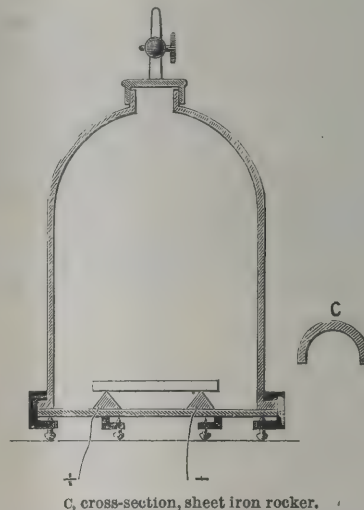

says that the passage of the current through the balls is attended by variations in its flow, according to the degree of contact of the balls and the calorific effects between the same. Wiedemann also states that the formation of sparks and the voltaic arc, together with the expansion of the electrodes by the calorific action of the current, can give rise to a vibratory movement of the electrodes between which such actions take place. If two carbon points are fastened to two elastic wires which by their pressure hold the electrodes together horizontally, then when the electric circuit is closed, a "clattering" noise like a series of small explosions is heard, and the passage of sparks and the formation of the electric arc between the electrodes is heard. The vibrations produced in this manner are imparted to the wires, and can be viewed, and felt by the fingers.

Mr. Berliner and others, in order to disprove the theory that the microphonic action is produced by a film of rarefied or heated air between the electrodes, placed the latter in a vacuum chamber. It is not necessary for me to describe the result of these experiments; but in this connection I call attention to the experiments of Reitlinger, described in the *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften*, Vienna, A.D. 1862, page 453. The article is entitled "Tones and some Phenomena of Motion Produced in the Closed Circuit of a Galvanic Current." After reviewing the experiments of Paalzow, Forbes, Gore, and others,\* and stating that the electrode of an electrical Trevelyan instrument will rock under water, he describes certain experiments performed in a vacuum chamber with a sheet iron semi-cylindrical rocker resting upon knife-edge bearers. The experiment can be illustrated by the following sketch.

In this experiment it was not necessary to start the

rocking motion by an impulse, the electric current passing across the contact points, produced the rocking motion. Reitlinger, like others before him, attributed the rocking motion to electro-dynamic repulsion, and

C, cross-section, sheet iron rocker.

to disprove the "heated air" theory, he performed the operation in a vacuum. The close analogy to microphone contacts in a vacuum is apparent.

In Poggendorff's *Annalen der Chemie und Physik*, vol. 124, A.D. 1865, Buff describes his experiments on the production of sound by electricity. After referring to prior experiments of Poggendorff, who placed a sheet metal tube, slit lengthwise, around an electro-magnet, and produced tones in the metal cylinder when the edges of the slit were in incomplete contact, and an interrupted current was passed through the electro-magnet. Buff describes his own experiments, which I have illustrated by the sketches below.

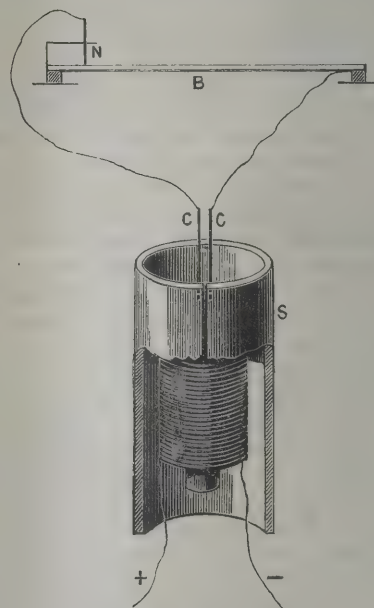

FIG. 1.

N, needle; B, brass plate; C, C, copper wire; S, sheet metal tube slit lengthwise.

In sketch fig. 1. the slit sheet metal cylinder of Poggendorff is used as a transmitter, in which currents are induced by an interior electro-magnet, through which intermittent currents are passed. The receiving instrument is a brass plate, upon which rests a needle electrode that will set the plate in vibration. It is stated that the cause of this vibration is due to "the incomplete contact and consequent increase of resistance at the contact points between the needle and the plate." It is also stated that "when the point of incomplete contact is made of a piece of fine platinum wire, or fine sewing needle, whose *slightly oxidised* point rests upon the plate, then with a current of suitable strength, the point is heated to incandescence, and then when the

\* Reviewed in my former articles.—A. M. T.

current is not too rapidly interrupted a perceptible variation of the incandescence phenomena at the contact points is observed. It is apparent that similar variations, although not visible to the eye, are present when the contact points are not heated so much. If this theory is accepted then the sound produced is due to heat effects at the contact points." Referring to Buff sketch fig. 2, the description which warrants the

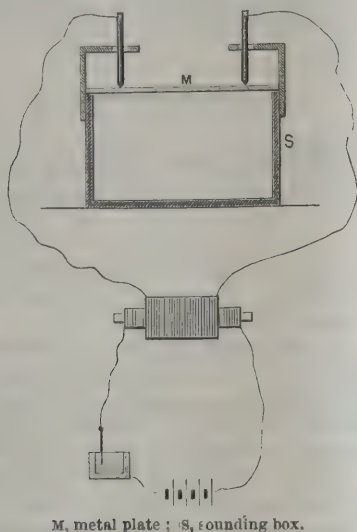

FIG. 2.

same states that a metal plate rests upon a sounding box, and that two needle electrodes bear loosely upon said plate and are connected with the secondary circuit of an induction coil. The primary circuit of this coil contains a circuit breaker which may be either a rotary "make and break," or a mercury cup in which a wire is immersed that is drawn out to break the circuit. In this connection and as having a very pertinent bearing upon the question, as to whether the arrangement with a mercury circuit breaker will not produce a practically continuous induced current, I cite the "Archives de l'Electricite," vol. 5, A.D. 1845, p. 222, in which De La Rive in his article on the production of musical sounds by intermittent currents, says: "A mercury rheotome produces more sustained sounds and slighter shocks, since by the same the interruption of the current is more gradual and not sudden as with a toothed wheel, this being due to the fact that the slight amount of mercury which always adheres to and goes out with the needle when the latter is drawn out of the mercury." In this connection I also cite "Etude sur la Téléphonie," by Dr. Rothen, Berne, 1884, page 93, where Prof. Hughes is quoted as saying that in the reversibility of the microphone (as receiver) the vibration of the diaphragm is in consequence of the variations of the temperature at the point of contact, and that the expansion and recession of the material (contact) produces blows against the diaphragm, and hence causes the same to vibrate. Those who are familiar with the French microphone of Pollard and Garnier, will readily perceive that the "microphone receiver" of Buff closely resembles the same, since both have sliding rod shaped electrodes resting loosely upon a diaphragm. Before closing my review of references which, in my opinion, deprive the *instrumentalities* used in the modern microphone almost, if not entirely, of all novelty, I wish to call attention to a newly published fact that I have discovered concerning the Reis telephone. In the *Annales Telegraphiques*, Vol. VII., A.D. 1864, page 592, it is stated that "the telephone of Reis would be an admirable instrument if it realised in a perfect manner the hopes of the theory. Without prejudging the future, it is well to recognise that it is not yet perfect. When the gamut is produced at the transmitter it takes a well trained ear in order to recognise the sounds in the midst of the vibrations (tremblements) to which it is subjected. Besides this, the model instru-

ment of which we speak is exposed to several causes of error, since the membrane will, at certain moments, not vibrate with the same amplitude, thus occasioning at times want of contact. If the sound emitted rests *within* neighbouring limits *the contact is prolonged*. This inconvenience is avoided by substituting for the voice of the operator a tuning fork furnished with a vibrator (système trembleur), then the note is more precise, although always very weak.

It is not my intention to detract from the merit of the discovery that the loose contact electrodes of Mousson, Rollman, and others, can be set into vibration by the human voice, and thus used for the transmission of speech, the object of the present article being mainly to show that almost all the theories advanced concerning the operation of microphonic contacts were known many years ago, and, as at present, there were men at that time adherents of the "repulsion," "heated air," "arc," and "condensed air" theories. As I stated at the commencement of my present article, the microphone did not require the discovery of the principle that light electrodes placed in loose contact will, by a change of position, or the diminution and increase of the contact surfaces, serve to effect a change in the tension of a current flowing across said contacts. This phenomena was carefully studied by Prof. Mousson, and it only remained for Prof. Hughes to select a known form of variable contact rheostat, just as Bell and Gray used a liquid rheostat in their original experiments. A mercury rheostat, it may be added, was also used in Prof. Mousson's experiments, and he considered the same the equivalent of solid metal bodies placed in loose contact one upon the other.

## ELECTRIC LIGHTING IN MINES AND DAMP SITUATIONS.

WITH the object of overcoming the difficulties which are met with in preserving the insulation at switches, cut-outs, or lamps in the tunnels and workings of mines, Mr. R. Oliver G. Drummond, electrical engineer to The De Beer's Consolidated Mines, Limited, of Kimberley, South Africa, has designed the following fittings:—

The switches\* (fig. 1) and fuses are mounted on spe-

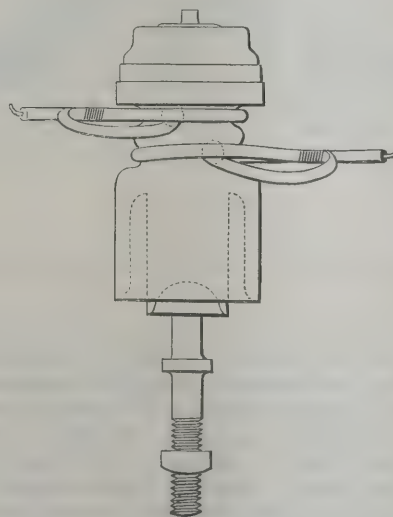

FIG. 1.

cially designed bases, insulated from the bolt that secures them to the timber or roof, and fitted with a cover to keep off the dust, &c., and to protect the workmen from shocks. The wires are drawn in from the

\* The arrangement of the switch seems liable to allow dripping moisture to percolate between the switch turn and the opening in the cover through which it passes.—EDS. ELEC. REV.

lower side of the base, and consequently the dripping water cannot run up the lead into the switch or the fuse. With these fittings there cannot be any appreciable leakage, except where there is a large amount of moisture in the air and consequent condensation on the sides of the insulated bases.

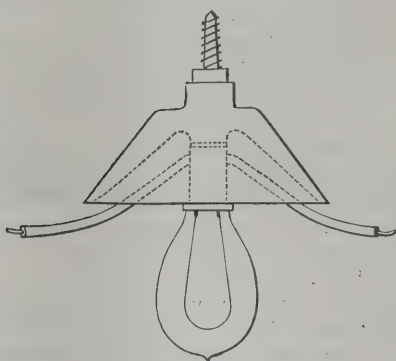

FIG. 2.

The lamps are suspended from a holder (fig. 2) fitted inside a porcelain insulator, which is of such a shape that it becomes a reflector to the lamp, throwing the light downwards, and the heat of the lamp rising into this insulator keeps it warm and dry, no matter how full of moisture the air is. Any water dripping on to it from the roof runs off the outside of it, so that the lamps and holders are thoroughly insulated; and faults from bad insulation are impossible. The bracket lamp is designed of a shape suitable for fixing to the sides of the tunnel, and is fitted in an insulator with the same results as the hanging lamp. The reflector in this case is of such a shape that the light is thrown upwards, downwards, and sideways.

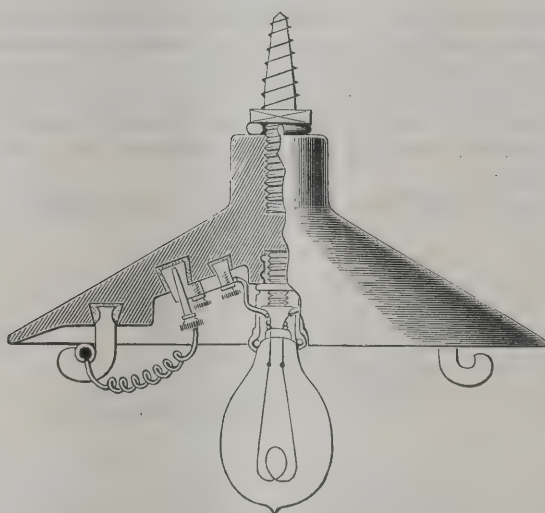

FIG. 3.

When it is necessary to hang lamps in very wet places, the combination fitting (fig. 3) is recommended, as the switch and cut-outs are arranged inside the reflector or porcelain insulator, and as will be seen the heat of the lamp is utilised to keep the insulation of these fittings good. The two hooks are used to suspend the conductors, and as the joint for the branches to the lamps are taken from here, the insulation of these joints is kept good by the warm air rising from the lamp. This fitting has many advantages in rock tunnels, or places where it is necessary to suspend the wires from the roof by insulators, and where there is no timber to attach the wires, lamps, cut-outs, or switches to, and consequently holes have to be bored in the rock, and wooden plugs driven in them. In these tunnels it is generally expensive to bore holes in the roof, as the rock is very hard, and the re-

quired position of the holes is the most difficult for boring, so that the less there are the better. For these reasons the combination fitting was arranged to carry as much as possible. It takes the place of a bracket for two insulators, a support of one switch, two cut-outs, and a lamp-holder, thus one hole suffices for five. The fitting is, moreover, very efficient, as the heat of the lamp is utilised to keep all the necessary parts in connection with the lamp dry, and also the joints and branches from the main wire. The fittings, we may mention, are manufactured by The Electrical Engineering Corporation.

### SOUTH AUSTRALIAN POSTAL AND TELEGRAPH CONFERENCE.

THE following are the principal resolutions, with reference to telegraph matters, carried at the conference held in Adelaide during May, 1890:—

1. That the following terms for reduction of cable rates, as proposed by the Eastern Extension Telegraph Company, be accepted, namely:—"Firstly, the tariff will be reduced to 4s. for ordinary messages, 3s. 6d. for Government messages, and 1s. 10d. for press messages during one year of trial. If at the end of the first year no very serious loss is involved, the experiment will be continued for two years more, and such extension must be at the option of the company. If the loss should be nearly recovered at the end of the three years, the arrangement will be extended for the remainder of the subsidy. The whole proposal is conditional upon South Australia accepting 5d.—the transit rate." (Queensland dissented.)

"2. That in the event of South Australia reducing the telegraph rates on the trans-continental line, in accordance with any resolution agreed to by this conference, the several colonies represented at this conference, including South Australia, agree on the basis of population to guarantee to South Australia a revenue from the line equivalent to that received at present." (Queensland dissented.)

"3. That any colony or country not joining in the contribution to subsidy and guarantee, shall pay proportionately higher rates."

"4. That it be a recommendation to the various Governments represented at this conference. 1. That between any two contiguous colonies 1s. shall be the initial charge for twelve words, and 1½d. for each additional word; names and addresses to be paid for. 2. Between any three colonies 1s. 6d. to be the minimum charge for twelve words, and 2d. for each additional word. 3. Between Queensland and Western Australia 2s. to be the minimum charge for twelve words, and 3d. for every extra word. 4. Tasmania to be a minimum rate of 6d. for twelve words for each colony, plus the cable rates. Twelve words to be considered the minimum rate. Addresses and signatures to be paid for, and code addresses to be prohibited. 5. That the reduced rates come into operation on January 1st, 1891."

"5. That it is considered desirable to adopt a system of urgent telegrams, at double rates, locally and inter-colonially."

"6. That the Uniform Intercolonial Telegraph Regulations, as drawn by heads of departments, be adopted."

"7. That in the opinion of this conference it is very desirable that the heads of the Post and Telegraph Departments of the Australian colonies should frequently meet—annually, if possible—to consider and report to their respective Governments on all questions affecting the postal and telegraphic services generally."

"8. That the President forward to His Excellency the Governor of South Australia a copy of the resolutions agreed to by the conference regarding the reduction of postal and cable rates to the United Kingdom, requesting that his Excellency will forward it to the

British Government by cable, with the expression of the earnest desire of this conference that, as England is equally interested with the colonies in securing and maintaining cheap telegraphic communication, the proposal of the conference that Great Britain should contribute towards the subsidies and guarantees required may be accepted by the Imperial Government."

"9. That the President inform the Agent-General of South Australia of the acceptance by the conference of the amended offer of the Eastern Extension Cable Company, and request him to confer with the Agents-General of the several colonies represented at this conference in order that they may jointly urge upon the Imperial Government their acceptance of the proposal that England should contribute one-half of the subsidies and guarantees required in order to secure the reduced rates agreed to for telegraphic communication between England and the colonies of Australasia."

The colonies represented at the conference were New South Wales, Victoria, South Australia, Queensland, and Tasmania.

### SOME NOTES ON GUTTA-PERCHA.

THE *Annales Télégraphiques* in its September-October issue, contains an interesting communication on the gutta-percha tree. We reproduce some portion of this article.

The word *gutta* (*guetah* or *gueutta*) in the Malayan language means, in a general sense, gum or birdlime, something sticky. The word *percha* or *perfia* means a rag or a strip of cloth, and describes accurately enough the appearance of those gums which, previous to their treatment in hot water, are not unlike rags pressed, and in a partly pasty condition. The idea that *percha* or *perfia* signified *Sumatra* is an error participated in, till lately, by all travellers.

The existence of gutta-percha was made known to the civilised world in 1842 by Montgomerie, the claims of the explorer Tradescant to priority of discovery not being established. The first specimens were brought to London from Singapore in 1843 by José d'Almeida, and the remarkable properties of these gums were speedily made known by Hancock. To Wheatstone must be given the credit of seeking to employ gutta-percha in the insulation of telegraph conductors, but Walker in 1849 in the Channel cable first attempted a practical application.

Since that date many experiments have been made with the view of discovering a substitute for gutta-percha, which is daily becoming more difficult to find, and more costly; in submarine telegraphy the best quality can only be employed, and all attempts up to the present have failed to replace it. The gum of the African *Bassia Parkii* and of the Guiana *Mimusops Balata* have only given negative results; as to the *Payena Leerii* it is used, and to a considerable extent, for the adulteration, in the forests, of the better gums.

The only gums which are suitable for use as insulating material in submarine cables are obtained from the trees of the species *Isonandra*. These plants, which are treated by many botanists as belonging to the species *Palaguium* or *Dichopsis* in the desire to establish a finer distinction, have their natural and exclusive habitat in the Malay archipelago. The extirpation of this species in Malaysian forests proceeds with rapid strides; the natives in cutting down every tree at all productive, and pursuing the same course with the second growth, that is to say, preventing the plants from attaining their full development, have during the last 40 years completely destroyed any possibility of reproduction and multiplication.

The gums, such as were employed in early days for industrial purposes, are now only found occasionally; those which have replaced them will follow the same fate before another 15 years have elapsed. Exportations from Malaysian ports are rapidly diminishing. The inadequate plantations created in the Dutch East

Indies are principally composed, not of the better classes, but of those producing the most abundant sap, that is to say, of inferior varieties. Submarine telegraphy is on the point of finding itself deprived of the species indispensable to it in its operations and extensions.

In chronological order the plant first made known as being the source of a gutta-percha was the *Isonandra Gutta* of Hooker. This tree, the only one whose coagulated sap (sent to Europe at the same time as were the specimens of the plant) has met with practical success, has remained but imperfectly described. It is treated as a species extinct, since 1857, in the island of Singapore, and as existing only in Malaysian forests. As a matter of fact, it has become exceedingly rare, but it is yet to be met with; its fully grown representatives were still to be found in 1887 on the Chasseriau Estate situated in the ancient forest of Boukett Timah (hill of tin) in the centre of Singapore, where the tree was discovered by the botanist Thomas Lobb in 1847. When the plant was again met with in Singapore in 1887, all collecting had there ceased for at least 30 years.

This *Isonandra*, known as the *Isonandra Gutta* of Hooker, the *Dichopsis Gutta* of Bentham and Hooker, and the *Palaguium Gutta* of Baillon, arrives at maturity at the age of 30 years. Its trunk has then a height of from 40 to 44 feet to the lowermost branches, it is cylindrical in shape, and has a circumference of about 3 feet at a height of from 3 to 6 feet from the ground. It flowers every two years after the age of 30. The shape and size of the leaves of the *Isonandra* vary so much, according to the age of the tree and the situation of the leaf, that some confusion has been created in the case of many specimens which have been wrongly assigned to different varieties.

In the Malaysian forests there are only five trees which can be confounded with the *Isonandra Gutta*, partly owing to a kindred foliage, but to a greater degree from the similarity of the saps. No confusion is possible with the other *Isonandra*, which are themselves separated by the *Payena Leerii* (gutta seundek). The guttas seundek, as known in commerce, are nothing but complex mixtures.

The author of the article, M. Sérullas, differs in some measure from the conclusions arrived at by M. Seligman-Lui, who it will be remembered visited the percha producing districts of the Eastern Coast of Sumatra, in 1881, on behalf of the French Government. The *Payena Leerii* is quoted by M. Seligman as possessing most valuable properties, whereas M. Sérullas distinctly qualifies it as an inferior variety. The practical value of the Dutch plantations at Buitzenborg (Java) also forms a point of difference; M. Seligman not only attaches great importance to the probable results of this experimental cultivation, but actually describes the operations as being very successful, and the method most efficient.

### THE ARGENTINE-EUROPEAN CABLES.

THE Buenos Ayres press has been of late engaged in a controversy as to the merits and defects of the concession granted to Messrs. Bieckert & Co. for a direct cable between the River Plate and Europe.

It was rumoured, not long since, that the present Government of the Argentine Republic had decided to annul the concession, but more recently it is announced that this statement was incorrect, inasmuch as the concession has been ratified by President Pelligrini and General Racas.

The journals unfavourable to the concession point out that the nation, whose finances are in anything but a flourishing condition, lays upon itself the burden of having to pay a guarantee of 5 per cent., for 20 years, on a capital of 11,000,000 gold dollars, and they draw the attention of their readers to the fact that another association of capitalists had made an unsuccessful attempt to obtain the guarantee of 5 per cent., for 10 years only, and on a capital of only 9,000,000 gold dollars. For

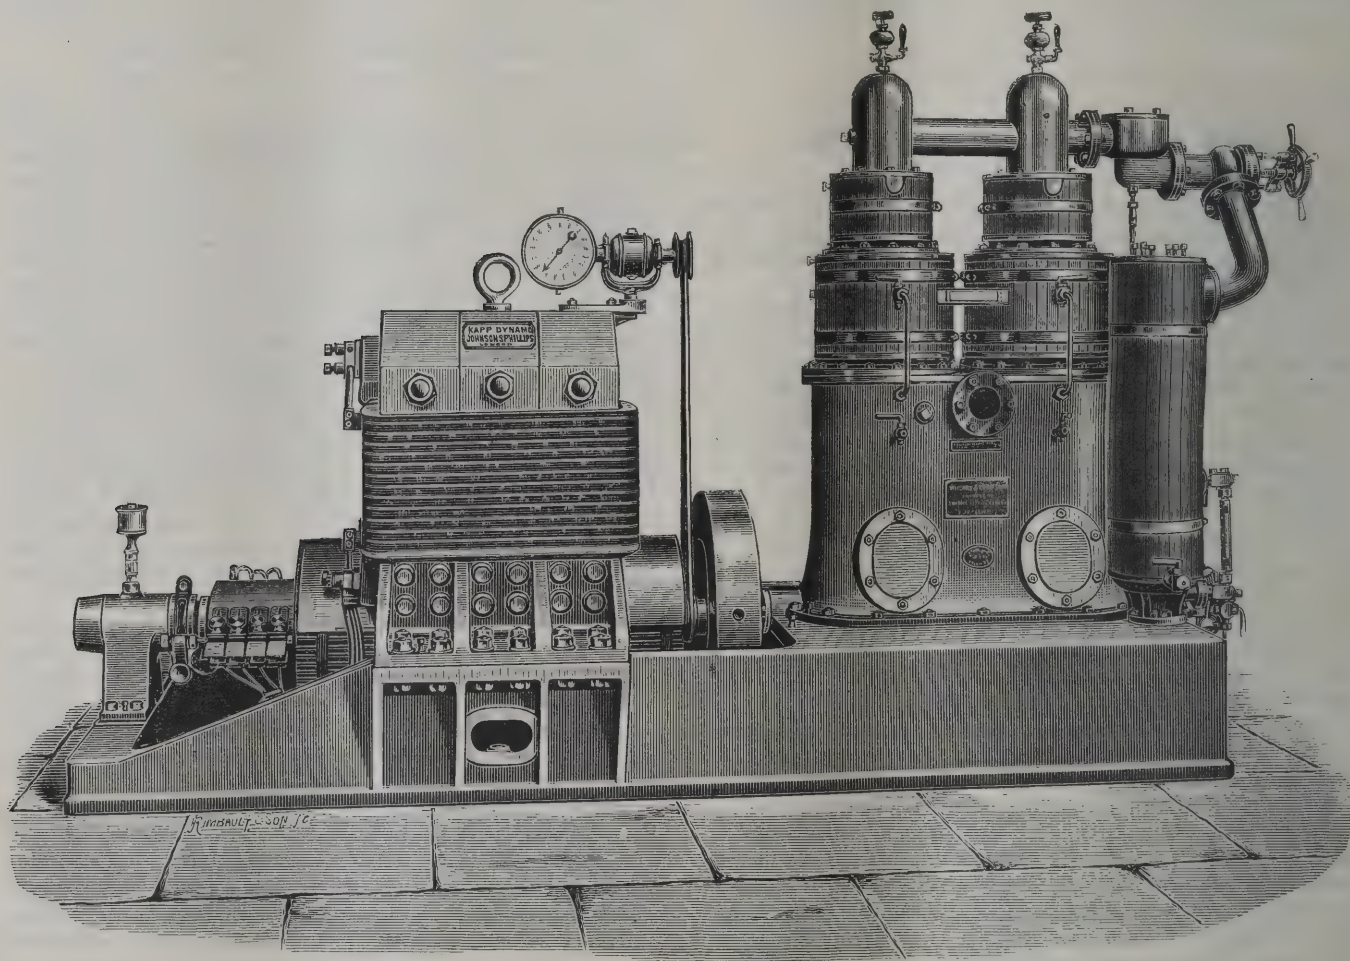

this reason, and also on account of the rumours and suspicious current as to the part played in the transactions by certain high functionaries, it would have been more seemly, say these journals, had the Government entered into a careful investigation of the circumstances under which the concession was originally granted.

Attention is also called, as a motive for deprecating any assistance on the part of the Government towards the laying of new cables, to the very ample telegraphic communication existing between the River Plate and Europe, more than sufficient, indeed, for the requirements of the country. On the east coast of South America, in addition to the cables of the Western and Brazilian Company, which it is expected will be shortly duplicated, two land lines connect Monte Video with Pernambuco. This point is joined to Europe by the Brazilian Submarine Company's cables, and another cable route *via* the West Indies and the United States,

paid by the Brazilian Submarine Company during the last few years are quoted as follow : 1881 to 1882, 7 per cent. ; 1882 to 1886, 6 per cent. ; 1886 to 1888, 7 per cent. ; and 1888 to 1889, 7½ per cent.

### ELECTRICITY AND MINING.

IN the course of his inaugural address—on coal mining—delivered before the Manchester Geological Society last week, Mr. J. S. Burrows, F.G.S., referred to the subject of the lighting of mines. He had but little to say regarding the electric lighting of mines beyond the use of primary and secondary battery lamps, neither of which he at present considered to be a success. The President's address was followed by a speech made by Mr. Merivale, who could "conceive of a time when

WILLANS-KAPP STEAM DYNAMO.

is about to be established. On the West Coast of the Continent, communication with the United States *via* Galveston is obtained through the Transandine land lines, the West Coast of America Company's and the Central and South American Company's cables. The latter company is now actually engaged in laying duplicate cables between Valparaiso and Lima, so as to accelerate the transmission of through telegrams.

The journals favouring the action of the Government in granting the concession insist upon the value to the Argentine Republic of an independent and direct communication with Europe at a low tariff. Such a scheme would possess the additional advantage of avoiding the territories now connected by the existing system. At the present tariffs, it is intimated that there is an annual exchange of over a million words between the Argentine Republic and Europe, and it is calculated that the low tariffs to be charged on the new cable will materially increase this quantity. To lend the scheme a more captivating appearance, the dividends

electricity would be carried throughout the workings of a colliery, both to give light and supply power." Before electricity could be applied to this extent, many difficulties would have to be overcome, such as sparking at the brushes. He referred to the few instances of the application of electricity to mining operations in this country, and believed that this agent would in time "revolutionise both their defective means of lighting and their old-fashioned plan of getting coal by hand labour." Sparking at the brushes was, however, his bugbear; but this difficulty, as is well known, has already been overcome in many machines on the market, whether running at full or less than full load.

The dual subject raised by the two speakers is one which is gradually being brought into greater prominence among mining engineers and mine owners in this country. Portable electric lamps of the primary and secondary battery types will probably come into use in time, but owing to their high price and inconvenience of recharging, it is fair to assume that they

will not be extensively employed. It appears more probable that the electric lighting of mines will be conducted on similar principles to those adopted in private installation work, that is to say, the generating plant will be suitably installed and the lamps placed along the roadways, whilst portable lamps will be used where the leads have not to be carried. In this connection it is interesting to note that the Fife Coal Company have announced their intention of introducing the electric light in their pits at Leven, the lamps to be placed 15 yards apart along the roads.

The application of electricity for pumping and hauling purposes at St. John's Colliery, Normanton, in the Forest of Dean for pumping, at Llanerch Colliery for pumping and hauling, and at Llanlithgow for pumping purposes, has shown by actual working results that electricity is more economical than compressed air or steam plant. Electric coal cutters were "demonstrated" some three or four years ago, but, beyond this, nothing seems to have been heard of these machines. We are informed, however, that an English firm has supplied electric coal cutters for nearly four years, and that the plant is running successfully. At present, details regarding these machines are for obvious reasons withheld, but practical working data will in the course of a few months be forthcoming, when the subject will be brought before the notice of the engineering world.

TRIALS OF A WILLANS-KAPP STEAM  
DYNAMO.

WE give the result of the economy trial of a Willans-Kapp steam dynamo which Messrs. Johnson and Phillips have built for the Birmingham General Post Office.

[COPY.]

CONSUMPTION TRIAL.—No. 982.

Engine. No. 982. For Birmingham P. O. Barometer 30.3 falling. Dy. No. 83. Date August 8th, 1890. Present, Mr. Low.

Indicated H.P. = 79.7. Electrical H.P. = 67.4. Commercial efficiency = 84.6 per cent. Total water per hour, including escape from jet cocks, 1,807 lbs. 27 lbs. of steam per E.H.P. hour.

New Electric Construction Works at Wolverhampton.—The new electrical construction works at Bushbury, on the north side of Wolverhampton, will be ready for occupation before Christmas, and will give employment to some 1,500 hands. The company has sufficient contracts on hand to keep the works in active operation for some time to come.

NOTES ON CENTRAL STATION ELECTRIC  
LIGHTING.\*

By CHARLES H. YEAMAN, Assoc. Inst. E.E., Stud. Inst. C.E.,  
City Electrical Engineer, Liverpool.

At various times the industrial applications of electricity have occupied the attention of this Society; and of these, the most taking has without doubt been the calorific or thermal effects of the current practically used in the arc and incandescent lamps. In March, 1885, a paper was read on "Electric Lighting from Central Stations," drawing attention to the American and English stations then supplying current, and blaming the Electric Lighting Act of 1882 for the tardy development of the heavy electrical industries, and more especially that of the public supply of electricity.

Since the date of that paper, the Amendment Act of 1888 has been passed, and the first fruits of its lightening of the burdens borne by the craft of electrical engineers are to be seen far and wide. The difficulties which had previously beset the use of electricity in this country had taken the shapes of mad speculation and legislative restriction. The lessening of these difficulties has removed most of the impediments to the extension of electrical works. That this is the case, is proved by the number of central stations projected and in use all over the kingdom, in connection with schemes which have sprung into being since the passing of the 1888 Act. The present position of the industry, technically, is one of friendly antagonism between the devotees of some half-dozen systems, any one of which would probably, in competent and experienced hands, prove successful, and each has certain advantages and disadvantages compared with its rivals.

The problem of a commercial supply of electrical energy throughout an extended area directed attention to the question of the pressure or voltage to be employed. The lamps at present on the market do not allow of any very great choice in this respect, the lowest pressure for a 16 C.P. incandescent lamp being about 50 volts, and the highest a little more than double that value.

There are special types of lamps to be had of somewhat lower and higher voltages, but, generally, they do not give satisfaction; and, as standard pressures for the lamp circuits are generally adopted, and as the price of the lamp is its chief drawback, any great multiplication of standards is to be deprecated. The Brush Company prefer 60 volts, Sir William Thomson advocates 80, The Metropolitan and London Electric Supply Companies and Messrs. Crompton usually specify 100, and here in Liverpool 110 volts is maintained on the canalisation. The Westinghouse Company, of America, have adopted 50 volts for their lamp circuits, and it is understood that the Sardinia Street Station of the Metropolitan Company, in London, run on this system, has also taken the American practice as its basis.

For isolated plants, where the dynamo was only, at the most, a few dozen yards from the lamps, a simple parallel low tension supply satisfied all requirements, and was both economical and sufficiently elastic in working to make any elaborate regulating arrangements unnecessary. As the distance to which the current had to be transmitted was increased, it was found that either the network of mains required to be large, unwieldy and costly; or that the loss in pressure was excessive, and that lamps of different voltages were required to compensate for the variations in voltage as the distance from the supply increased. On the simple tree system of working, it was impossible to keep within anything like the limits of the variation permissible by the Board of Trade Rules, and the system of feeders and feeding points, as proposed by Edison, was used where possible. On a low-tension network properly laid out, aided by feeders, it is commercially possible to work within a radius of a quarter of a mile from the station, and carry out all the regulations under law as to the maximum pressure and the allowable variation.

As at this point it might be expected something should be said regarding Liverpool electric lighting, the writer would only soothe the fears of those who dread shocks, by assuring them that there is, in the system at work in this city, no possibility of personal danger, and that the danger of fire has been very efficiently guarded against. As Messrs. Holmes & Vaudrey, the engineers of the company, are members of this society, it is not desirable to trench upon anything they might wish to say in the future about their own work, and as one can always gain information about the Liverpool work by personal enquiry, it is proposed to look further afield for stations to be discussed.

One of the first difficulties that the supply companies had to grapple with, was the small encouragement given them to lay underground mains, and they were compelled, if they intended to supply at all, to go overhead, so much were they opposed on attempting to break up the public streets. Of course it was quite out of the question to run heavy circuits of copper strap or large cable aerially, and some method had to be thought of, by which to supply customers at great distances, and with a fairly large quantity of the commodity called "Electricity," which, be it noted *en passant*, requires to be defined, if one is to use it generally. Electricity to the public means energy, to the technologist it denotes current, a very different thing. The thing the public want, and which they are quite willing to pay for, and handsomely

\* Paper read before the Liverpool Engineering Society, January 29th, 1890.

too, is electrical energy; this is not simply current, but the value found by multiplying the numeric of the current by that of the pressure in case of a current flow in one direction or uni-ward, but which is, with alternating or periodic currents, equal to  $\sqrt{f \cdot e^2} \times \sqrt{f \cdot c^2 \cos k^0}$ , the square root of the mean square of the electromotive force, multiplied by the square root of the mean square of the current, multiplied by the cosine of the angle of lag between the impressed E.M.F. and the resulting current.

Since the aerial cables must be kept of moderate size, and it is well known that the carrying capacity of a cable is limited to a certain number of ampères, or a certain current, quite independent of the pressure under which that current flows, and the energy—that which is desired to be transmitted—is proportional to the product of the two factors, an attempt was made lately, and successfully, to increase the voltage under which the current flows, thus decreasing its volume with a given output of energy, and enabling a smaller size of cable or weight of copper to carry a supply of electrical energy a given distance with a given loss, than would be required with the pressure used up till that time. Regarding the loss in transmission, it must be remembered that the loss is a loss of head or pressure, and that it is analogous to that in a pipe, where the friction reduces the available head so many feet per hundred yards per rate of flow. The point where the analogy fails is the fact that friction has not a numeric as if it were a physical quantity like mass or specific heat. The question of high tension electric supply is very much like the problem solved by Mr. Ellington, in his power distribution scheme by high pressure water. Since by doubling the pressure we quarter the area of the conductor, or what is the same thing, reduce its weight per unit length to one-fourth, it will be seen that with a given loss per cent., the weight of copper required to transmit a given quantity of energy, a given length is inversely as the square of the volts employed. That this is so may be easily seen, if it be kept in mind that the loss in distribution is proportional to the current density in the conductor. Let  $c$  represent the current and  $e$  the voltage at which that current is to be distributed, then  $c \times e$  represents the total energy; and, if  $R$  be the resistance of the copper core, the loss will be  $c^2 R$  watts; therefore, the percentage loss will be

$$\frac{c^2 R}{c \times e} \times 100$$

If  $c \times e$  watts be distributed at double the first pressure, or  $2e$ ; the current will be reduced to  $\frac{c}{2}$ ; and, if the loss is to remain at its previous value,  $c^2 R$  must now be  $(\frac{c}{2})^2 4R$ , and the percentage loss becomes

$$\frac{(\frac{c}{2})^2 4R}{c \times e} \times 100; \text{ i.e.,}$$

the weight of copper required has been reduced to one-fourth, with the same loss. Therefore, with overhead conductors, two things are gained by using high tension. (1.) A lighter conductor to transmit a given quantity of energy; and, (2.) A smaller per cent. loss with given density of current.

As has already been pointed out, high pressure cannot exist across the terminals of a lamp, and therefore some appliance, called a transformer, secondary generator, or converter, must be inserted to deliver the energy of the high tension electric supply to the lamp at the voltage for which it is intended. The general theoretical law of these transformers may be thus expressed:—

let  $e$  = Primary H.T. E.M.F. in volts.  
 $c$  = " " " Current in ampères.  
 $E$  = Secondary L.T., E.M.F. in volts.  
 $C$  = " " " Current in ampères.

then  $e \cdot c = E \cdot C$ , or the energy of the two sides of the apparatus should numerically equate. This it never does, but the efficiency or energy got out i.e.,  $\left(\frac{E \times C}{e \times c}\right) \times 100$ , may at full load be 95.

In Mr. Vaudrey's paper, read before this Society in 1887, the question of electrical energy and its factors is fully dealt with.

The relative values of the two factors, the product of which, multiplied by time, gives the work done, may be varied as desired, and herein lies the beauty of all transforming systems. The primary circuit may be common to several transformers, and yet the secondary circuits may give any voltage, and any current desired; in fact, they may even work at a greater power than the primary circuit possesses.

The power of an electric circuit is expressed in watts, and the watts = energy expressed mechanically, or  $c \times e$ . The work =  $c \times e \times \text{time}$ .

The principal disadvantages of transforming systems are—

(1.) Low percentage duty.

$$\text{Per cent. duty} = \frac{c \times E \times \text{time}}{e \times c \times \text{time}} \times 100$$

(2.) Low percentage efficiency at low power, i.e., when not up to full load.

$$\text{Per cent. efficiency} = \frac{\text{watts got out}}{\text{watts put in}} \times 100$$

$$\text{or} = \frac{c \times E}{e \times c} \times 100$$

(3.) The high tension is dangerous to life. There can be no gainsaying the fact that personal safety is jeopardised by excessive

pressure. There is the greater tendency to leakage to earth, and its attendant difficulties and dangers which are clearly foreshadowed in the Board of Trade regulations.

(4.) There is the dependance of a sub-district or area of lighting on a single piece of apparatus, and the insertion of another chance of failure between the dynamo and the lamps.

The transformers may be of various kinds.

- A. Continuous current transformers.
- B. Alternating current transformers.
1. Storage or battery transformers.
2. Non-storage or magnetic transformers.

These latter may again be divided into—

- a Moving or dynamotors.
- b Fixed or molecular.

All of the 1 class are at present A. All of the B class are at present b, those of a type have not found much favour, and are used principally in conjunction with those of class 1: they are therefore continuous.

The alternating current molecular transformer has by far the most extended application at the present time, and if the balance sheets of the stations under that system will bear perusal, it bids fair to hold its own with all the other systems combined.

To obtain the advantage of high pressure, transformers may be coupled in two ways like other electrical apparatus:—

- C. In series, like arc lamps, constant current system;
- D. In parallel, like glow lamps, constant potential system.

Alternating molecular transformers are usually coupled. D system and battery or chemical transformers in the C system. This is based upon reasons of simplicity rather than anything else, as it is a simple matter to obtain a constant current continuous, but hardly possible alternating, and because the effect of induction does not militate against a single wire carrying a continuous current, but a single wire through which an alternating current was flowing, would render telegraphy and telephony almost impossible for some distance around.

The cost of the generators in the two transformer systems is about the same, and any possible difference in this item will have but a very small effect on the total cost, of which it becomes a very small factor. The low pressure of the ordinary parallel system, the perfect protection from excessive current obtained by the safety devices in use, and the continuous character of its current, render it practically inert so far as its effect upon existing property is concerned. That the alternating system, with its strong inductive influence, will occasionally cause trouble to existing telegraph and especially telephone lines, seems inevitable.

The chief advantage with the battery transformer system is, that it is possible to spread the work of the engines over as long a period, within the 24 hours, as may be found convenient, so as at all times to work the engines at full power. When, on the other hand, the supply is taken direct from the machines, the engines must, at each moment, develop whatever power may be then under demand. It is well known that, with modern compound or triple-expansion engines, such as could be most advantageously used for central station work, the coal consumption rises very rapidly per indicated horse-power, as the output is diminished. This becomes a most serious consideration, when the maximum demand bears an undue relation to the mean. In many cases the maximum demand is five or six times the mean daily average, and lasts only half an hour or so.

Methods adopted in central station lighting:—

1. Series system with battery transformers. Example: Chelsea.
2. Series-parallel system. Example: Hastings.
3. Three wire system. Example: St. James's and Pall Mall, London.
4. Parallel system with batteries. Example: Kensington Court.
5. Alternating transformer system. Examples: West Brompton—Lowrie Hall system. Glasgow—Ferranti system. Bournemouth—Morley system.

#### 1.—SERIES SYSTEM WITH BATTERY TRANSFORMERS.

Example: Chelsea.

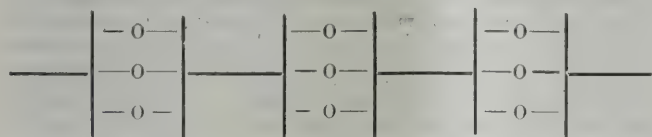

Following the order of the list of stations, Chelsea, with its stations for generating and distributing on the "King" system, first demands attention. The whole of the regulating and supply mechanism is automatic, the changing of the various battery stations in series alone being dependent on human energy and foresight, the system is extremely simple to work, but very complicated in erection, and it is doubtful if such a mass of interlocked automatic appliances is desirable, or if its life will be what is fondly hoped for. The system is an elaboration of the Beeman, Taylor and King station, which was laid down in Colchester in 1884, and of which a full account is contained in Mr. Fleming's paper of March, 1885, so that the description need not be repeated. The present plant, generating and distributing, and method of working, has been made public in a very complete and valuable paper, read by Major-General Webber, before the Newcastle-on-Tyne meeting of the British Association, in September of last year, and as nothing in the space available here could do justice to the subject, the writer begs to refer those interested to that paper.

#### 2.—SERIES-PARALLEL SYSTEM.

Example: Hastings.

The use of transformers in a high tension circuit is to allow of flexibility and remove any restrictions to supply that otherwise

would be imposed on the consumer. Hastings is an example of a high tension system without transformers, which has been working most successfully since 1881, and is now supplying over 1,000 incandescent lamps of 8 C.P. and 30 volts, the lamps being grouped in parallels of 16. This station, prior to the introduction of transformers, constituted the most successful instance of long distance distribution, not merely in this country, but anywhere. Brighton started also as a series-parallel supply, but has lately been altered to Lowrie Hall alternators. The principal feature which strikes one at Hastings is the extreme simplicity of the generating plant. The motive power consists of two 40 H.P. Robey engines and boilers, the engines being belted on to a counter-shaft rather below the level of the dynamo platform, and from which the five "Brush" constant current dynamos are driven by endless belts. These machines give 2,000 volts and 10 ampères. One is reserved as a standby, one is used for the arc lamps on the parade, the 30 arcs of 2,000 C.P. loading the machine fairly well up. The glow lamps are used in hotels and private residences, and these machines are run on the same number of separate circuits. The current flowing is proportional to that required by each lamp, multiplied by the number of lamps in parallel, and the pressure is equal to that required by one lamp, multiplied by the number of groups in series.

C = Current for one lamp.

E = E.M.F. " " "

N = Number of lamps in parallel.

M = " " groups in series.

F = E.M.

C = C.N.

C = Total E.M.F.

E = Total current.

The principal objection to a constant current supply is the fact that individual lamps of a group are dependent on their neighbours of the group, and no economy results unless the group of 16 lamps are turned off.

There are in Hastings underground circuits aggregating 20 miles of single wire,  $\frac{7}{16}$  strand, double G.P. and braided, drawn into 4-inch cast-iron pipes, with test boxes every 100 yards. The terminal pressure of the dynamo is regulated by a Brush carbon regulator, which maintains the current constant at 10 ampères, and in the supply circuit is placed an Ayrtton and Perry ammeter. The general method is to make a fixed charge per annum, which is settled by agreement.

The machines at Hastings are simple arc lighters, and give a current of 10 ampères suitable for arc lamps; they are used for incandescent lighting by grouping a number of incandescent lamps in parallel, so that they absorb the 10 ampères, and these groups are then treated as single arcs might be by being placed in series, i.e., one after the other.

### 3. THREE-WIRE SYSTEM. PARALLEL SERIES.

Example : St. James and Pall Mall, London.

The three-wire system is one attempting to do away with the inter-dependence of the individual lamps, and does not involve transformers, while it retains to a great extent the advantages of high pressure. In this system the number of lamps in series is reduced to two, and the groups in parallel are increased. Edison in America, and Hopkinson in England, have improved and perfected the system, allowing each lamp lighted to be quite uninfluenced by the number of lamps alight elsewhere on the circuit. The practice is now to run two dynamos of equal output—and voltage in series—and between the positive (+) of one and the negative (-) of the other, to string the incandescents in series of two. By this means the pressure is double that of the simple parallel system, and the weight of copper required is only one-fourth that of a two-wire network. As, however, the lamps are two in series, turning out one lamp would also extinguish its fellow. To avoid this a neutral wire or equaliser is run from the junction of the two dynamos to the middle connection of the groups of lamps, thus rendering each lamp independent.

The finest example of this method of working is the new station of the Pall Mall and St. James's Company in Mason Yard, Duke Street, St. James, London. The boiler room and dynamo room have been dug out underneath the yard, and a three story fire-proof building of white brick is carried on iron girders and pillars in the centre. The station is laid out for a total capacity of 20,000 16-C.P. lamps. Six Davey-Paxman boilers supply steam to 10 Willans central valve engines, capable of developing 210 H.P. at 350 revolutions, and two smaller ones capable of developing 80 H.P. The engines are mounted on combination bed-plates, upon the other halves of which the field magnets and bearings of the dynamos are supported, the armatures being coupled direct to the engine shafts. The field magnets of the dynamos are vertical, with poles downwards, and supported by brass brackets from the bed-plates. Regulation is effected by inserting resistance into the magnet circuits, which are shunts on the main. The generating sets are arranged in two rows of six each, one on either side of a central gangway towards which all the commutators of the dynamos are directed. The connections from the dynamos pass through suitable regulating and safety appliances before reaching the switchboard from whence the three-wire feeding network is supplied.

The underground system is an air insulated culvert, and the largest main consists of eight strips of copper 2 inches wide by 0.1 inch thick, forming the (+) and (-) leads, while the neutral wire is formed of four strips the same size. The strips are supported by porcelain insulators, and spaced by means of porcelain jockeys, the whole being carried in a cast-iron culvert. This distributing system consists of a complete ring, fed by heavy feeders, and with radial distributors running out beyond the ring. From each feeding point, pilot wires run back to the station, so that the pressure at each point can be ascertained. The pressure on the ring main is kept constant at 107 volts, and houses connected to this main are supplied with 106 volt lamps. Three load diagrams taken towards the end of December, 1889, give evidence of the very high proportion borne by the mean to the maximum demand.

### 4. PARALLEL SYSTEM WITH BATTERIES.

Example : Kensington Court.

This station, laid down by Messrs. Crompton, was the first station in London under the Electric Lighting Act, and has been extremely successful. At present there are two boilers by Marshall, 15 feet long by 4 feet diameter supplying steam to three coupled Willans engines and Crompton dynamos, one capable of lighting 1,600 16-C.P. lamps, and the two smaller 500 lamps, each of 50 watts. The speed of the dynamos is 370 to 400 revolutions per minute, and the consumption of coal 2.5 lbs. E.H.P. per hour. The load in the station at the end of last year was 1,500 lamps, many of these being 8 C.P., the favourite size on the Kensington Court estate, which is supplied at its limits as far as 950 yards from the generating station. The mains consist of bare copper conductor, laid in a brickwork and cemented culvert having a concrete bottom, and running under the footway. The culvert is 18 inches x 5 inches deep, and is divided into two channels by a mid-feather of brickwork in cement, and the whole is covered with flagstones. In the longitudinal channels thus formed, the copper conductors are strained over porcelain insulators, standing on short iron uprights fixed to the bottom of the channel, and the straining is effected by brass shackles, insulated by glass supports. The insulation thus obtained has been very perfect, and no trouble has resulted so far from moisture. A secondary battery of "Howell's" type is used to supply current when the machines are not running, and to aid the dynamos during the excessive discharge, for a short period each evening.

### 5. THE ALTERNATING TRANSFORMER SYSTEM.

Examples : West Brompton, Glasgow and Bournemouth.

The model station on the alternating system is certainly that of the House-to-House Company, Limited, who, basing their designs on what had been done at Brighton, Hastings, and Eastbourne, have overcome some of the difficulties of a commercial supply with a periodic current. Their station at West Brompton, situate as some say between the "quick and the dead," lies between the Metropolitan District Railway and the London and Westminster Cemetery, with a frontage to the Richmond Road. The completed station will contain 12 sets of plant each, capable of supplying 4,000 16-C.P. lamps, the engine and boiler room, offices, workshops, testing rooms, engine and drawing offices, taking up a plot of land, 470 feet x 60 feet. Three of the sets of plant are down; and although powers were only obtained in October last, nearly eight miles of underground mains have been laid, and current is supplied to 7,000 incandescent lamps, increasing by 500 per week on its circuits, and it is running permanently and supplying these by meter. Fowler's horizontal coupled compound engine, of 200 H.P. 30-inch stroke, 88 revolutions per minute, drives by seven cotton ropes,  $1\frac{1}{2}$  inch diameter, from a 14 foot flywheel, a Lowrie-Parker dynamo, with fixed armature and rotating field magnets, capable of maintaining an output of 100 units at a speed of 350 revolutions per minute. The E.M.F. is 2,000 virtual volts, and the periodicity 83. The revolving field magnets are supplied with magnetising current by an exciter driven by four  $\frac{3}{4}$ -inch ropes from the shaft of the alternator. This is a series wound Elwell-Parker continuous current machine giving 8 ampères. All wires are brought underground to the testing room, and are brought up at the back of the switchboard, so that it is impossible to touch the high tension connections. The switchboard is constructed in chinaware mounted on ebonite, and connection between the dynamos and mains is made by insertion of the connecting block with four brass pegs. Any circuit can be connected to any dynamo, and it is impossible to short circuit a machine, by reason of the distance of the brass pegs.

The regulation of the dynamo is effected to within 1 per cent. by means of the Lowrie-Hall regulator, which utilises the thermal effects of the current as a means of maintaining a constant E.M.F. across the terminals of the alternator. A thin wire attached at its extremities and weighted at the centre, is connected across one coil of the armature of the alternator, and by its sag allows a rocking arm to make contact with one or other of two tables connected to the two coils of the variable resistance fixed above the wire chamber. The liquid resistance is in shunt with the field magnets of the exciting dynamo, and by weakening or strengthening its field varies the magnetising current to the alternator, and, therefore, the pressure across its terminals. This current at 2,000 virtual volts is distributed underground by means of lead-covered cables drawn into gas pipes, 3, 4, and 5 inches diameter, with joint boxes at suitable intervals.

The mains are of special make, being Fowler-Waring cables, manufactured under Tatham's and Waring's patents. The insulation

is the highest yet made for cables, being stated as over 3,000 megohms per mile. The insulation consists of fine braidings saturated with a patent solution, and the cable is then lead covered, and has a coating of hemp over all. The cables are made in five standard sizes to supply 2,000, 1,500, 1,000, 500 and 250 10-C.P. lamps at a distance of 1 mile. The largest cable of this make in use is  $\frac{37}{16}$ . These cables are not exclusively used by the House-to-House Company, but have been found the most satisfactory up to the present. It is somewhat curious that lead covered conductors should be found so satisfactory for use, with alternating currents, in this country, as there is a great tendency for a spark to break down the dielectric on account of the induced currents in the lead, and in America elaborate apparatus is inserted to do away with this tendency. The cables were also used to carry the 10,000 volts that Mr. Ferranti proposes to use to convey the electrical energy from Deptford to London, and certainly these have been the only cables which have withstood the voltage employed by the London Electric Supply Corporation for any time, and, though they subsequently developed faults, the tension was phenomenal, and no research has up to the present demonstrated what goes on when an abnormal pressure is employed.

Before reaching the switchboard the current has to pass through a high tension fuse consisting of a long length of fine copper wire. The steam supply to the engines is maintained by six Babcock-Wilcox water-tube boilers, capable of evaporating 5,500 lbs. of water per hour, and requiring not more than 1 lb. of best Welsh coal per 10½ lbs. of water evaporated. Working pressure, 150 lbs. per square inch.

The secondary generators or converters, are coupled in parallel on the high tension circuit, and reduce the pressure from 2,000 virtual volts in the primary, to 100 virtual volts on the secondary, with a corresponding increase in the ampère. The Lowrie-Hall transformer is one of the "core" class, that is, it has two sets of coils and only one core. It is built up of thin iron plates, each plate being separately insulated from the rest to prevent eddy currents. On each of the individual cores a primary and secondary coil is wound, part of the core projecting beyond the coils at both ends. The coils are then placed side by side, and the plates of the projecting cores are turned over alternately, each pair of plates forms a closed magnetic circuit insulated from the rest, and the two individual cores forms one endless magnetic circuit.

One of the principal points in a system of public supply is that of measurement of the quantity of electricity supplied, and this is an especially difficult problem with alternate or periodic currents. Messrs. Lowrie, Hall and Kollé, have succeeded in utilising the principle of Edison's chemical meter for this purpose, by inserting into the lamp circuit an electrolytic vessel, and cell of constant electromotive force, which will therefore add its difference of potential to one phase, and subtract it from the reversed one, thereby creating a difference in the total quantity that has passed round the circuit positively and negatively. The equivalent therefore is obtained of a continuous current of an amount proportional to the number of lamps that are on the circuit, and the quantity of metal lost by one plate and gained by the other measures the total number of lamp hours or Board of Trade units.

#### GLASGOW AND BOURNEMOUTH.

Two other systems of high tension alternate current distribution deserve notice as being like the Lowrie-Hall, complete in themselves from generation to dissipation. These are the Ferranti and the Mordey. Glasgow is favoured by having an overhead network of conductors working at 2,400 virtual volts, and as the station worked by Mavor and Coulson is a typical one, it is interesting to compare it with the others.

The station was laid down on ground acquired by Messrs. Muir, Mavor and Coulson, Limited, in Little Hamilton Street. The engines, boilers, and dynamo are on the ground floor, which has an area of about 1,400 square feet, and the plant at present at work is capable of supplying 1,750 16-C.P. incandescent lamps. By the end of this year it is expected another engine and dynamo will be in working order, doubling the power of production. A loco. type steel boiler supplies them at a pressure of 100 lbs. to the square inch, to which feed water is supplied by a Worthington steam pump capable of delivering 2,000 gallons per hour at a slow speed, a self-starting injector capable of feeding two boilers, and a Berryman feed heater.

The motive power consists of a compound non-condensing horizontal tandem engine of the Putnam type, with tappet and cam valves, with cylinders 14 and 22 in. diameter, by 42 in. stroke, and indicating 200 H.P., at 85 revolutions, the flywheel being 14 feet in diameter. This drives by rope gearing a Ferranti alternator 4 feet in diameter, at 450 revolutions per minute, weighing in all 7 tons, and carrying its own exciter on the armature shaft. The exciter, which is shunt wound, supplies 30 ampères at 95 volts to the field circuit of the alternator. Special arrangements have been made for continuous running, in order to maintain a constant supply day and night. A reservoir of oil with level gauge glass is erected above the machine and supplies a constant service to the bearings, the oil passing then to a reservoir from which it is pumped back again.

The switchboard is a double pole one with means of throwing over the distributors on to the Siemens alternator which has an output of 250 ampères, at 50 virtual volts, and is on Kennedy's plan raised to 2,400 virtual volts by means of a large station transformer (which plan has lately been suggested for Deptford as being safer than having 10,000 volts on the dynamos). The small alternator is driven from an inverted cylinder compound

engine of 50 H.P. by rope, and is used for the supply during the small hours of the morning. The periodicity of the Ferranti current is 67. The facility with which the field magnets can be separated and the armature exposed for examination is a great practical advantage. On the switchboard are fixed two ampère gauges, and an electrostatic voltmeter of Sir Wm. Thomson's design, the gauges being in the high tension circuits, and the voltmeter being across the terminals of the alternator which is coupled to the supply circuits by means of six fuse boxes also mounted on the switchboard, one for each cable of each circuit and three double pole switches. The fuses are made up of lengths of fine copper wire about one foot long, and are fixed in vulcanite supports at each end of an earthenware box, which is made with internal ridges so as to cause the fuse to blow at a number of places at once. These boxes are ordinarily covered by an earthenware lid. From the double pole switches the six cables pass out of the station on porcelain insulators to the circuits.

Of the six overhead circuits, one supplies the Municipal Buildings, and the others radiate out west, north, and eastwards. In the Municipal Buildings 1,100 lamps are in use, and the current is supplied by meter, that of the Aron pattern, being fixed on the circuit to the six transformers coupled to the various lamp circuits inside the building. Generally, however, the Schallenberger meter is used, and is giving satisfaction, probably superseding the Aron, as its accuracy is greater. It consists of a circular iron disc placed on a vertical arbor attached to connecting mechanism, and also carrying a fan to introduce resistance to movement by air friction. The iron disc rotates very freely. Two diameters of this disc are chosen inclined to each other at 45°. A coil of copper ribbon fixed to the case is coiled round each of these diameters; one of these coils is connected with one of the wires going to the lamps, and the other is closed on itself, and the latter has therefore induced currents circulating in it attaining a maximum a quarter of a period later than the main current, that is when the main current is at zero. Thus we have a continuous rotation of the iron disc when an alternating current is flowing in the main coil. It is a very convenient type of meter for alternate currents, the only objection being that its indications vary with the speed of reversals of the alternating current: our best governors are not perfect, and our most reliable suppliers of electricity would be tempted to alter its indications by increasing the speed of the engines a little.

The Aron meter consists of an ordinary clock with a coil of wire for the bob of the pendulum, and below this is fixed a coil of wire, carrying the current going to the lamps. The effect of the current is to diminish the influence of gravity on the pendulum, and thus cause the clock to lose time. The loss of time as compared with a good uninfluenced clock shows the number of units of electricity which has passed through the instrument. The fact that the clocks require to be wound up militates greatly against the general adoption of this meter, and there are several minor objections to it. The Ferranti converters used in Glasgow are of the shell type, with two cores and one coil, and seem to be equally efficient with the Lowrie-Hall. It will be clear that the exact disposition of the coils and core is immaterial so long as the relative position is maintained: that is, a primary electric inducing circuit linked to a secondary induced circuit by means of a magnetic circuit closed through the primary and the secondary.

The system in use at Bournemouth, and lately laid down at Bournevalley, 2½ miles from the town, is that largely brought out by Mr. Mordey. It is generally accepted that transformers, though economical in that the generating station may be a long distance away from the consumers, do not do away with the necessity for a low tension distributing network; and that therefore the system is worked on the principle of one large generating station, and several scattered distributing stations, having large transformers supplying within a radius of something like 200 to 300 yards; and both Mr. Ferranti and Messrs. Lowrie and Hall know this. Mr. Mordey, on the other hand, prefers to allow a transformer to be placed in each consumer's premises, and his system is designed to admit of the greatest flexibility in this respect.

The Bournemouth station is built on a very large plot of land, acquired by the Brush Company, conveniently situated as to supply of fuel and water, and quite free from the objection to the site of former electric works, in so far as there are no risks of causing inconvenience or annoyance from vibration or other trouble to residents. The company have erected a building covering 3,200 square feet, and divided into two by a partition wall forming the boiler and engine rooms. The boilers are made by the Babcock-Wilcox Company, and are of 150 H.P. each. The motive power is furnished by two inverted cylinder compound engines, designed by Raworth, the engineer to the Brush Electrical Engineering Company, of 75 H.P. each. The dynamos are Mordey alternators, each capable of supplying the primary circuit of converters, lighting in all 2,000 lamps. The exciter is a Victoria machine, driven by friction gear, by a smaller engine of the same type as those driving the high tension dynamos. The speciality of the station is the splendid appliances for switching, and the care which has been devoted to minor details, such as fixing a jockey pulley to tighten the endless rope driving.

There seems to be a general desire for uniformity expressed in central station work, as low tension machines are now nearly always driven direct by Willans engines, or high-speed direct-acting engines of a like type, so that a medium speed dynamo may be coupled to the engine shaft.

It is usual in present practice to keep the pressure constant, not at the station, but at some point about the centre of the supply network; and in this connection a volt indicator is quite as useful

in regular work as a voltmeter. It is scarcely necessary to explain that by the term indicator is meant an apparatus which will show whether the volts are or are not at their normal value, and, if not, in which direction they are at fault. Such an instrument has only to be calibrated for one particular value, and ought for that reason alone to be much cheaper than a meter. Moreover, as it is only intended to be used at one current strength, there is no objection to the employment of soft iron.

Probably some use might be found for an alternating current volt indicator. The principle of alternating current deflection to which Prof. Fleming in this country, and Prof. Elihu Thomson in America, have devoted attention, would obviously lend itself to this end. The writer is not aware of any application having yet been made of this principle to any instrument for electric lighting work.

The problem of electric lighting from central stations is comparatively easy, if plant can be put down near the centre of the area to be supplied, with the right of way, and powers granted by a provisional order.

When permission can be obtained to lay cables underground, a three-wire system at 220 volts, or continuous current transformer system at 500 volts, has much to recommend it in comparison with the alternating current. Much has been said on the subject of the cost of copper; and the habit of basing estimates of the cost of a network on the price of copper is one to be avoided, having led to erroneous conclusions much too favourable to systems using high E.M.F.

There can be no doubt that there is a possibility of the high tension circuit making contact with the low tension circuit winding in an alternating transformer, and since the former is always joined to the supply leads of the network, there is a constant loss due to want of balance between the primary E.M.F., and the back induction of that coil. With low tension working the highest efficiency occurs during the minimum load, that is for the greater part of the twenty-four hours; while with the high tension, alternating current, the highest efficiency is at full load, and for the greater part of the day the loss is very high—higher than the loss in the low tension system when working at maximum load.

To sum up; on examining all sides of the question, the rival merits of the various systems seem very evenly balanced; each method of distribution is showing itself, *under given circumstances*, to be a sound and practical system to adopt; each method has its own special advantages and disadvantages, and time alone can show which of the many proposed is fittest to survive upon the largest scale; or whether they are all doomed to fall before a system combining the merits and avoiding the demerits of all others.

## LONDON COUNTY COUNCIL.

At the weekly meeting, held at Spring Gardens, the Chairman of the Highways Committee submitted the following report:—

The Electric Lighting Acts impose on the council the duty of testing meters for electric energy supplied for any purposes. In order to perform this duty properly, we are advised that the meters should be tested by means of a current the same in quality, character and periodicity as that for which the meters are to be used. It is therefore desirable that the council should obtain power to require any electric lighting company to supply energy to the testing station now being established, and to any others which may be hereafter established, where such testing station is beyond the limits of the company's area of supply, such energy to be used only for the purposes of testing. They, therefore, recommend that the Parliamentary Committee be instructed to insert in the Council's General Powers Bill of next session a clause giving the council power to require any electric lighting company to supply electrical energy to the council's electric testing stations, even if the station for which the supply is required be beyond the limits of the company's area of supply, and authorising such company, subject to the usual notices, to break up streets for the purpose of laying the mains necessary to afford such supply to the testing station.

The Electric Supply Corporation has served two notices, one (registered No. 128), dated October 30th, 1890 (1 plan), of intention to lay mains in West Strand (part of), Charing Cross (part of), Northumberland Avenue (part of), and the other (registered No. 129), dated November 3rd, 1890 (1 plan), of intention to lay mains in the Strand (part of), and Bedford Street (part of). The proposed interference with so busy a thoroughfare as the Strand is to be deprecated; but the company had statutory power to lay its mains there, and although it has endeavoured by negotiation to adopt a route for these mains in the area of supply of an adjoining company, so as to avoid to some extent the interference with the Strand, it has been unsuccessful. In these circumstances, they were of opinion that the council would not be justified in withholding its consent to the works referred to in the notices, and recommend that the sanction of the council be given to the works referred to in the two notices (registered Nos. 128 and 129), of the Electricity Supply Corporation, dated October 30th and November 3rd, 1890, respectively, upon condition that two days' notice be given to the council's engineer before any of the works are commenced; that the concrete floor of the road-boxes be made 9 inches thick; that the York stone at the top be 4 inches thick; that the longitudinal girders in all the boxes be

laid on 3-inch stone templates the full thickness of the brickwork; that the work when commenced shall be continued by day and night shifts, and be carried on so that the traffic shall not be interfered with more than is absolutely necessary; and that the work shall be completed within the shortest time possible.

They had considered a notice (registered No. 130), of the Westminster Electric Supply Corporation, of intention to lay mains in Chesterfield Gardens (1 plan). There appears to be no objection to the proposed works, and recommend that the sanction of the council be given to the works referred to in the notice (registered No. 130), of the Westminster Electric Supply Corporation, dated 6th November, 1890, upon condition that the company do give two days' notice to the council's engineer before commencing the work; that the mains be laid under the footways wherever it is found practicable to do so; and that the covers of the boxes to be used shall consist of iron frames filled in with materials to suit the paving.

A notice (Registered No. 131), dated 6th November, 1890, has been received from the Metropolitan Electric Supply Company, of intention to lay mains in Exeter Street, Strand (1 plan). The proposed works are of the same character as those of this company previously sanctioned by the council, and recommend that the sanction of the council be given to the works referred to in the notice (Registered No. 131) dated 6th November, 1890, of the Metropolitan Electric Supply Company, upon condition that the company do give two days' notice to the council's engineer before commencing the works; that the mains be inclosed in 5-inch iron pipe, and be laid under the footways wherever it is found practicable to do so; that the covers of the boxes to be used shall consist of iron frames filled in with material to suit the paving; and that the works generally shall be of the description approved by the council on 1st October, 1889.

They had considered a notice, dated November 11th, 1890 (Registered No. 132), from the Kensington and Knightsbridge Electric Lighting Company, of a proposed extension in Church Street (1 plan), and a further notice (Registered No. 133) from the same company, dated November 12th, 1890, of a proposed extension in Hyde Park Gate. The works referred to in these notices are of the ordinary character and it was recommended that the sanction of the council be given to the works referred to in the two notices (Registered Nos. 132 and 133) of the Kensington and Knightsbridge Electric Lighting Company, dated November 11th and November 12th, 1890, respectively.

They had considered an application from the National Telephone Company for permission to lay two lead-covered cables along the entire length of the council's subways between the Mansion House and Westminster Bridge. We are advised that these are subways to which the Metropolitan Subways Act, 1868, applies, and that the council has no power to charge rent for the use of them, but can only make a charge for supervision. There appears to be no objection to these cables being laid in the subway; and therefore recommend that the National Telephone Company be allowed to lay two lead-covered cables in the subways between the Mansion House and Westminster Bridge, upon condition that the cables referred to be laid in such position as the council's engineer may direct, and that the work of laying them be carried out to his satisfaction; that all damage which may be done to the subway in the execution of the work be made good by, and at the expense of the company; and further that the company do undertake to pay such charges, in respect of supervision of all its cables now or hereafter to be placed in the subways, as may be agreed upon between the council and the company at a future time.

## THE ELECTRICAL BEHAVIOUR OF CERTAIN AMALGAMS.

A RECENT issue of the *Zeitschrift für Physikalisches Chemie* contains an interesting account of an investigation into the magnitude of the polarisation given by various amalgams in a solution of the corresponding chloride against zinc amalgam. The author is Mons. Le Blanc.

The apparatus employed in this investigation was of an extremely ingenious character; a prominent feature in it was a large tuning fork, which was so adjusted that its vibrations allowed the electromotive force of polarisation to be measured while the primary current was, practically, flowing constantly.

A means of estimating the relative stability of the various amalgams was afforded by the rate of fall of the degree of polarisation after the primary current was interrupted.

Le Blanc found that amongst the amalgams of the metals of the alkalis and alkaline earths, those of lithium and magnesium are the least stable.

A current of electricity from a battery of eight Leclanché cells was passed for about ten minutes in the case of a number of amalgams; with nearly all of

them there was but a very slight disengagement of gas. With the amalgams of magnesium and lithium, however, there was a comparatively active evolution of gas.

It was found by Le Blanc that when a mixture of solutions of zinc chloride and hydrochloric acid were dealt with, a quantity of zinc amalgam was deposited at the negative pole; this, he considers, indicates that atomic hydrogen displaces the metal zinc in its salts.

A new light is thrown upon the vexed question of ammonium and alkyl ammonium amalgams. Most of the text-books question the existence of ammonium amalgam. Let us take an instance and quote from a very well-known book. "When a solution of ammonium chloride is poured over sodium amalgam a soft slimy mass is formed, which swells up to many times the original bulk of the sodium amalgam. This curious substance has been termed an ammonium-amalgam, on the assumption that it was a combination of the radicle  $NH_4$  with mercury. In reality, however, it is nothing but a mercurial froth inflated with a mixture of ammonia and hydrogen."

Ammonium-amalgam was discovered "almost simultaneously by Berzelius and Pontin (vide Gilbert's *Annalen der Physik und Chemie*, vol. vi., p. 260) and by Seebeck (vide *Gehlen, Allg. Journ. Chemie*, vol. v., p. 482). It can be readily obtained when a current from a galvanic battery is passed through aqueous ammonia or through an aqueous solution of an ammonium salt containing metallic mercury placed in connection with the negative pole. The same substance is formed when a globule of mercury is placed on a piece of moistened sal-ammoniac and connected with the negative side of a voltaic battery of very moderate power, the circuit being completed through a platinum plate upon which the sal-ammoniac rests; decomposition of the latter rapidly ensues, and ammonium amalgam is formed. Sir Humphrey Davy described it as a butter-like mass of a grey metallic appearance, and much lighter than water. At ordinary temperatures it quickly decomposes into mercury, ammonia and free hydrogen, but at the freezing point it crystallises in cubes, and according to Grove does not decompose spontaneously.

Endless discussions have taken place over this amalgam, and the balance of opinion has been fairly evenly divided. Le Blanc's work sets this question at rest, for the phenomena which he observed with solutions of the ammonium chlorides are quite comparable with those obtained when the metallic chlorides are employed. This goes to prove that the ammonium and alkyl-ammonium amalgams have an actual existence.

These amalgams, however, as might be supposed, are much less stable than the metallic amalgams usually are—a point which is well illustrated by the fact that the electromotive force of polarisation falls off in a relatively rapid degree as the primary current ceases to flow.

Besides the interesting amalgam of the hypothetical radicle ammonium. Le Blanc investigated the following compound radicle amalgams:—

Methyl-ammonium amalgam.  
Ethyl-ammonium amalgam.  
Di-methyl-ammonium amalgam.  
Di-ethyl-ammonium amalgam.  
Tri-methyl-ammonium amalgam.  
Tri-ethyl-ammonium amalgam.  
Tetra-methyl-ammonium amalgam.

Of these the most unstable is tri-ethyl-ammonium amalgam, and it is rather doubtful whether it really exists. The tri-methyl and the di-ethyl-ammonium amalgams are also extremely unstable.

The formation of a mercury "froth" on the surface of the liquid during the process of electrolysis has hitherto been held to be a capital indication of the formation of an amalgam, but this view must be modified. Le Blanc's investigation shows that in the case of the ethyl-ammonium amalgam no froth rises to the surface, and yet the electrical behaviour shows beyond a shadow

of doubt that a definite and comparatively stable amalgam has been formed.

Those of our readers who know German, and may wish to examine into the details of this interesting piece of research may consult the "*Zeitschrift für Physikalische Chemie*," vol. v., commencing at page 467.

## FIRE AT GROSVENOR GALLERY CENTRAL STATION.

MR. FERRANTI has kindly supplied us with the following facts relating to the fire at the Grosvenor Gallery:—

"Up till recently the Grosvenor Station was supplying the whole of the lights of the London Electric Supply Corporation. Due to the obtaining of an injunction by the neighbours, the corporation has been obliged to abandon this station for generating purposes, and use it only for a distributing station. It was necessary, so far as was possible, to stop down the Grosvenor generating station, turn out a certain portion of the machinery which had been running there, and instal the necessary converting machinery for the purpose of transforming from the high tension to the intermediate tension for supplying to the customers. All this had to be done with the minimum of delay. It was, therefore, a case of stopping down on Saturday nights, and working as hard as possible to finish the installation of the transformer machinery by as early an hour on Sunday afternoons as possible. This process was partly done. The whole of the work which was put in was of an entirely temporary nature, India-rubber-covered wires being used for carrying the current, light woodwork being used to support these wires, and the switches instead of being upon permanent supports were held by woodwork."

"The accident occurred at 6:30 on Saturday morning, owing to the action of a linesman in plugging on a fresh set of converters. The man was not sufficiently cool for this particular purpose. Hesitating in putting on the switch, it arced slightly: instead of pushing it in, he drew it back and broke the contact. The heated surfaces, together with the 5,000 volts pressure which was being used, caused the arc to maintain. It ran up the woodwork and set light to the ceiling, which was composed of cross-boards with tar between for the purpose of keeping out moisture from the tank which formed the roof. The whole place was burned down in the brief space of twenty minutes. An hour after the accident occurred the whole place was quiet and fairly cool. The linesman had ample opportunity of entirely stopping any damage from his first carelessness, because the switch which he put on was only a plug, and meant for connecting a circuit, there being a large switch within a yard's distance for breaking the supply passing through the plug switches. If he had been too frightened to turn off the switch, he had again another safeguard in the safety switch at the end of the room, which would cut off the whole supply from Deptford. He also had the option of signalling to Deptford to stop the supply, but this was stopped before the man could have finished signalling, as they saw by the action of the ammeters and voltmeters at Deptford that something was wrong in London."

We believe that the cost of the destroyed apparatus amounts to between £15,000 and £20,000, all of which was uninsured.

**Electric Lighting in Panama.**—An electric light company, acting under contract with the Municipal Government, has introduced the electric light for public and private purposes in the town of Panama. The lighting of the streets is effected by 43 arc lamps, and 300 glow lamps are installed on private premises,

## NOTES.

**The Electric Light at Bath.**—At a meeting of the Town Council last week, Mr. Sturges, on moving the adoption of the report of the Special Electric Lighting Committee, complimented Mr. Massingham upon the success of his installation. He also congratulated Bath upon having taken the position it had done in the matter of the electric light, and upon this important and beautiful improvement in the lighting of the town and houses having been so readily adopted. He advocated an independent inspection by a leading electrician. Mr. Massingham had stated that he would be better satisfied if they employed an expert of the highest standing they could find—that was Mr. Preece; and he would move, as an addition to the report, that they employ a scientist of sufficient eminence to inspect the whole of the works and report to the council. Mr. Sturges added that the Board of Trade would insist on inserting a clause in Mr. Massingham's license that he should not be compelled to sell at the end of seven years, if he wanted an extension. Mr. Massingham, however, was perfectly willing not to have such a clause, but the Board of Trade insisted that he should. In the course of the discussion which ensued, General Burn expressed an opinion that the new illuminant was an immense improvement on the old gas light, and as a practical proof of its superiority he mentioned that a threepenny piece placed on the pavement between two of the electric standards could be seen easily, whereas it was impossible to detect a similar coin placed on the pavement between two gas lamps. At the close of the discussion the report was unanimously adopted.

**Electric Lighting at Stroud.**—A public meeting a few nights ago at Stroud approved of a scheme for lighting the town by electricity.

**Ship Lighting.**—Last week Messrs. David W. Henderson, Glasgow, launched to the order of Messrs. J. and A. Allan, the steel screw steamer *Mongolian*. She is fitted throughout with the electric light. A sister ship to the *Mongolian* will be launched in the spring of next year.

**French Submarine Cables.**—In reviewing the work now being accomplished in the West Indies by the Société Française des Télégraphes Sous-marins, and while congratulating the Ministry for the Colonies on the zeal it has displayed in this direction, the Paris technical press points out that there are other and more urgent telegraphic communications to be established. The places with the most pressing need for cable connection are Réunion, Maurice, and Madagascar, which represent most important interests, long suffering from inattention; the Comoro Islands and New Caledonia, also, claim the consideration of Government.

**Important to Electric Light Companies.**—At a recent meeting of the Paris Municipal Council the following measures were agreed to:—Parliament is invited to pass a special law to assimilate the electric lighting industry with those enterprises which, being considered dangerous, are under the constant supervision of the Prefecture of Police. The administration is invited to inscribe in the conditions of contract for electrical companies, whenever a new concession may be asked for, the express obligation to employ smoke-consuming apparatus, or to make use of combustibles which do not give off smoke.

**Canal Traffic.**—A German contemporary states that a Magdeburg firm will shortly make experiments on the Finow Canal with boats and timber rafts worked by electricity.

**A Bordeaux Exhibition.**—An electrical section is being formed in this international exhibition, which is to be opened in Bordeaux in May next.

**A Long Price.**—The English and German electric light companies in Madrid maintain the high price of 14d. to 15d. per unit. The expression "go to Bath," to inspect Mr. Massingham's lighting and charges, must now be changed to "go to Madrid."

**Italian Electro-Technical Schools.**—There are three electro-technical schools in Italy. One is situated in Milan, the second in Turin, and the third in Naples.

**Another Franco-Danish Cable.**—The President of the Republic has just signed a decree regulating the laying and working of a second telegraphic cable between Calais and Denmark.

**The Theatrephone.**—The theatrephone is about to be installed in several of the Paris clubs, notably in that of the Union Artistique, where it will shortly be at work.

**Personal.**—Sir Frederick Abel, F.R.S., has accepted the seat on the board of J. C. and J. Field, rendered vacant by the death of Mr. G. Maule.

**The Royal Society.**—The following papers were down for reading yesterday:—Prof. J. V. Jones, "On the Determination of the Specific Resistance of Mercury in Absolute Measure." Dr. Hopkinson, F.R.S., "Magnetism and Recalescence."

**The Old Students' Association.**—A Cinderella dance will be held at the Westminster Town Hall on Friday, December 12th, 1890. Tickets, 3s. 6d. each, may be obtained from the members of the committee, or from Mr. Reginald J. Jones, hon. sec.

**A Valuable Publication.**—The sixth edition of "Electric Lighting and the Management of Accumulators," by Sir David Salomons, Bart., will shortly be published.

**Tenders Wanted.**—Bombay.—Sealed tenders will be received by the Municipal Commissioner for the city of Bombay up to 1 p.m. on February 16th for experimental lighting by electricity of certain streets of the city of Bombay for two years. Forms of tender and schedule of conditions, and a sketch of the portion of the city, showing the streets to be lighted, may, on payment of £1 sterling, be obtained from Messrs. E. W. and R. Oliver, 1, Corbet Court, Gracechurch Street, London, E.C., who will, on application, give any further information that may be required. Tenders must be accompanied by a deposit of one thousand rupees in cash (not to bear interest), or in public securities for that amount to be paid to the chief accountant of the Municipality of Bombay, which will be forfeited to the corporation in case of refusal to sign the contract embodying the conditions mentioned in the schedule above referred to. A further payment, to make the total deposit equivalent to 5 per cent. on the contract amount, will have to be made by the contractor whose tender may be accepted, before signing the contract. Mr. Rienzi Walton, executive engineer, Municipality, Bombay.

**Edmonton.**—For lighting public hall, stores, &c., Letters to Mr. Walker, people's provider, Upper Edmonton.

**Mr. Tesla on Sound Views.**—In a letter to *Industries* on alternating motors, Mr. Nikola Tesla concludes an able letter as follows:—"You state that I have misinterpreted my results, and it looks as though you believe my views to be unsound. Your arguments are those of an eminent scholar. I was myself a fair scholar. For years I pondered, so to speak, day and night over books, and filled my head with sound views—very sound ones, indeed—those of others. But I could not get to practical results. I then began to work and think independently. Gradually my views became unsound, but they conducted me to some sound results."

**Failure of Accumulator Traction in Australia.**—The Victorian *Electrical and Telegraphic Journal* for last month contains the following suggestive paragraphs:—

"The Sandhurst and Eaglehawk Electric Tramway Company ceased running on Wednesday, 24th September, the accumulator system of traction having proved a failure. This will be noted with regret by the public as well as shareholders. The latter are worthy of much praise for the persistent resolve to succeed if success were attainable."

"It is curious to note that the only accumulator-driven system which was alleged to be a commercial success, that on the Barking Road, London, is now proved to be a commercial failure, to judge by the reports in the electrical press of late date."

"This company were using the same cars and motors as the Sandhurst Company. This latter company may, if the requisite power be obtained, adopt the overhead wire system, which has proved successful in America."

**Western Counties and South Wales Telephone Company.**—We must take this opportunity of expressing satisfaction at the continuous progress of this company, which forms at once an example for other enterprises with far greater pretensions. A few months ago the company was approached by the Port of Plymouth Chamber of Commerce with a view to establishing a signal station on Rame Head for reporting by telephone to Plymouth all vessels passing up or down Channel or entering the port, as well as casualties and other shipping news of interest. No time has been lost, and provided that arrangements can be made with the Admiralty, the station will be in working order in a few weeks. The Devon and Cornwall Homœopathic Dispensary and Cottage Hospital is in connection with the exchange system free of charge, and among the more recent developments of the system is the conversion of the single trunk line to Plympton, Ivybridge, and Avonwick into a metallic circuit or double wire. A tradesman at Plympton can now converse with any subscriber in the Three Towns for an annual rental of £10, and a private resident will have the same privilege for £5 per annum, provided he lives within a quarter of a mile from the Plympton office, £1 5s. per annum being charged for every additional quarter of a mile. Similar services to this will be established at other places early in the new year.

**Electric Light Mains.**—Messrs. Henley's Telegraph Works Company, Limited, has favoured us with samples of electric light mains covered with vulcanized India-rubber which the company has been, and is, supplying to the Kensington and Knightsbridge Electric Supply Company, Westminster Electric Supply Company, Notting Hill Company, Crompton & Co., &c. It is believed that the largest of these samples, viz., 61/10s is the heaviest vulcanized India-rubber cable that has ever been made. The weight of the conductor alone is  $7\frac{1}{4}$  tons, and its sectional area is  $\frac{3}{4}$  square inch. Judging from the samples before us, the company should feel itself well satisfied with its manufactures both electrically and mechanically.

**"Darkest England and the Way Out."**—The staff and men of the dynamo department in the works of W. T. Goolden & Co. having resolved to raise a subscription to aid General Booth in his great work of endeavouring to raise the lapsed masses of his fellow men, it was at once started vigorously, and chiefly through the sympathetic influence of C. W. Atkinson, Esq., the sum of six guineas was in a few hours collected and forwarded to General Booth last Saturday. The instrument department staff may possibly send in a contribution, but no definite steps have up till now been taken in the matter.

**A New Cable.**—The Great Northern Telegraph Company is about to lay a new direct cable between Fano, off the West Coast of Jutland, and Calais.

**Electrical Engineers Students' Meetings.**—There will be no students' meeting held on Friday next, as advertised. On the 5th proximo, Mr. Garret will read a paper on "Search Light Work."

**Catalogue.**—We have received a catalogue of technical books "On the Mechanical Arts" from the Britannia Company, Colchester.

**Telephones in Russia.**—A French company has recently obtained a concession from the Russian Government for the construction of a telephone system between St. Petersburg, Moscow, Warsaw, and Berlin. The charge for the use of the telephone will be 8 francs for the first minute, and 4 francs each additional minute.

**Prices of Incandescent Lamps.**—Mr. C. J. Robertson, writing from Aldersgate Street, says:—"I notice in your last issue a note on the present low price of incandescent lamps in the States (*i.e.*, 44 cents. each). I thought it might interest you to hear that I am myself supplying lamps (made within 300 miles of London), of a quality and durability second to none—including the 'Edison-Swan'—at the still lower price of 1s. 7d. (*i.e.*, 38 cents, American) each, fitted and delivered free, and there is every prospect of lowering this price in the near future."

**Tapping Holes in Porcelain with Fine Threads.**—Messrs. Buller's, Limited, send us the following note:—"From the paragraph in the REVIEW of last week, it might be inferred that there had been some difficulty in obtaining porcelain fittings for electric lighting with holes tapped to receive metal screws. For many years past we have tapped holes in porcelain to fit metal screws with complete success, and therefore when the demand for this feature in electric lighting ware came, we had no difficulty in meeting it. We beg to send you a ceiling rose with screwed holes, made by us some months ago. To our customers we have supplied many thousand pieces of ware with tapped holes, and the results have already been very satisfactory. Our screws are made to a series of standard gauges, which in diameter and pitch cover the whole requirements of the trade." Certainly the sample sent to us is an excellent specimen of manufacture, the screws running perfectly true and smooth.

**The Government and the Telephone.**—Under this heading an article appeared recently in the *Scotsman* in which attention is drawn to the Van Rysselberghe system of telephoning on ordinary working telegraph wires. It is stated that, "Hitherto not a step has been taken towards the adoption of the system in this country;" and again, "If it should be found as available here as it is in Belgium and in France—and there is no reason why it should not—the Government will have the most comprehensive means of telephoning to be found in the country," and much more to the same effect. The writer of the article was evidently ignorant of what he was writing about, otherwise he would not have argued in the strain he did. The Van Rysselberghe system has, we believe, been tried in this country and found to be a failure, first, because it necessitates the addition of electro-magnets in the line wire, which cuts down the working speed of the fast speed apparatus so widely used, and secondly, because the addition of these electro-magnets renders it necessary to greatly increase the ordinary working battery power of the telegraph circuits. In the case of Belgium, we believe, it has been found necessary to double the power on the circuits all round, and the consequent expense and trouble more than counterbalances the gain of telephone working being possible. It is whispered, also, that the Telegraph Service is by no means pleased with the system, but that it has, unfortunately, bound its hands in such a way, that they cannot be freed.

**Greenock Philosophical Society.**—Mr. A. Denny, Dumbarton, last Friday night, lectured to this society on "Electricity, and its Practical Applications." The hall was electrically lighted for the occasion, and the lecture was interspersed with numerous experiments and illustrations.

**The Institution of Electrical Engineers.**—The next meeting will be held on Thursday, 27th November, at 8.0 p.m., when the adjourned discussion on the following papers will be continued:—"The Efficiency of Secondary Cells;" "On the Chemistry of Secondary Cells;" by Prof. W. E. Ayrton, F.R.S., Vice-President; C. G. Lamb, B.Sc., and E. W. Smith, associates.

**The National Telephone Company's Exchanges.**—The National Telephone Company, Limited, announce that the trunk line between the London, Manchester, Liverpool, and Birmingham Exchanges is now open to the public.

**The Electro-Deposition of Copper.**—We have received since our Correspondence pages went to press a long letter from Mr. W. Stepany Rawson, who simply reiterates the contents of his previous communication without in any way making his case better. Out of politeness to him, and also to show how much more diplomatic it is to beat about the bush than to come to an issue, we shall publish his letter in our next, together with a report on the Elmore process formulated by M. Secretan and others, which is so deliciously vague that our readers may anticipate a real literary treat. We have failed to elicit the information from Mr. Rawson which we requested, for he steers clear of the rock on which he would have split by declaring that the Elmore Company has objected to the figures of cost being given by him. While on this topic, it may not be amiss to call attention to a letter from Mr. William Elmore, which appeared yesterday in the *Financial Times*. This gentleman's object is to allay the alarm which has been caused by the depreciation of Elmore shares, but we doubt very much whether his explanations will have the desired effect. So far as the company's works are concerned, says he, they continue daily to improve; but what the general public desire to see is not so much a daily improvement in works which are supposed to turn out some scores of tons of copper per week, and which certainly ought to have been in readiness months ago, as a real sale for the manufactured articles. We have every reason to believe that up to the present date five tons would cover all that the Elmore Company has turned out, and Mr. Elmore's statement that he has increased his holding of shares during the past week may show either confidence in his system, or, on the other hand, that he is trying to keep the market firm for yet a little while to float still another company. How near to the truth this last supposition may be we leave for commercially inclined readers to determine, merely calling attention to the following extract from an article "Still more Elmore," in the *Financial Times* of Wednesday, and which is well worthy of perusal in full:—"There are now four Elmore Companies, all producing no end of circulars and no end of securities, but no patent copper. Now there is to be a fifth. It is not to produce copper. Oh, dear no! It is to be called a Trust, and its function is to foist a lot of Elmore vendor shares, which of course are unsaleable just now, on the public. This is the prettiest thing in 'trust' schemes that has been evolved, and it is also the culminating point of the ingenuity of the Elmore promoters. The chief advantage of the scheme, as set out in the latest Elmore circular, is that the public will be enabled, by means of this trust, to invest in the valuable Elmore securities." To judge from the fall in the price of shares of the original company the public requires a good deal of persuasion to indulge in the luxury of Elmore securities at fancy values, and it is not likely to jump at the chance of obtaining diluted interest in the worst of them.

**The Northfleet Electric Tram Line.**—The series electrical traction system at Northfleet has been discontinued. The line, as is well known, was for demonstrative purposes only, and its object having now been attained, there is no further reason for incurring the large expense necessitated by the smallness of the local traffic, and the heavy rental and charges imposed by the Gravesend, Rosherville and Northfleet Tramway Company, through whom the Parliamentary powers were obtained. Careful accounts have been kept of the cost of running for the last six months, and from these, when audited, the actual cost of motive power on the series system will be made public.

**To Elmore Shareholders.**—On the 12th September, 1876, Mr. Henry Wilde, of Manchester, patented an invention (Specification No. 3,569) for "Improvements in the manufacture of metal rollers for printing calico and for other purposes." It may be interesting to the holders of Elmore shares to compare this with what they know of the process on which they have built their hopes, and for this purpose we give the following extract from the text:—"Now my present improvements consists, firstly, in a method of securing a sufficient amount of adhesion between the iron and deposited copper surfaces, to enable the roller to withstand the various engraving and other operations without the separation of the metals. For this purpose the iron roller, before receiving a coating of copper from a hot cyanide solution of copper, is heated to a temperature ranging from 150° to 212° Fahrenheit, by plunging it into boiling water, or by other means. The said roller, after receiving a film deposit of copper from the cyanide solution, is then transferred to the bath containing a sulphate solution of copper, where it receives one or more thin coatings of copper. *These coatings are subjected to considerable pressure by the action of a burnishing roller of hardened steel, for the double purpose of forcing the deposited copper into closer contact with the iron, and detecting any want of adhesion between the two metals.* The burnished coppered roller is then replaced in the bath of sulphate of copper solution, and *subjected to the action of the electric current until the desired thickness of copper deposit is obtained.* Before each of the depositing operations the surface of the roller is thoroughly cleansed by scouring and washing in clean water, as is well understood. Having thus stated the nature of my invention, and described the manner of performing the same, I declare that I claim,—First. Heating iron rollers to prepare them for receiving a film deposit of copper from a cyanide solution. Secondly. *Depositing one or more thin coatings of copper from a sulphate solution, and burnishing the same before the final coating is deposited for the purpose described.*

**Electrical Engineers Conversazione.**—The annual *conversazione* of this Institution was held on Wednesday, the 19th, in the Galleries of the Society of Painters in Water Colours, and was the largest and most brilliant of a long series. The company, numbering about 1,000, was received by the president, Dr. John Hopkinson, and Mrs. Hopkinson. A large number of distinguished visitors and scientific men were present, including the Solicitor-General, Sir Frederick Bramwell, Dr. Gladstone, Prof. Frankland, Sir Albert Cappel, Sir James Douglass, Sir Douglas Galton, Sir David Salomons, Sir Henry Mance, Major-General C. E. Webber, &c. The Coldstream Guards' band played in the Galleries and the Bijou Orchestra in the Prince's Hall. Ladies formed a very considerable portion of the concourse, and added brilliancy to the scene.

**The Mistake Obvious.**—In reference to our note last week, "A 200,000-watt Arc Lamp," Mons. W. de Fonvielle writes to explain that by a misprint in a French contemporary, 50 volts became 500. The mistake, we need scarcely say, was doubtless apparent to our readers, and, as our correspondent remarks, is scarcely worth referring to again.

**Electric Light at Madame Tussaud's.**—A complete installation of the electric light at Madame Tussaud's has been erected by Messrs. Drake and Gorham, superintended by Mr. Gisbert Kapp. Two dynamos are used, driven by two of Crossley's gas engines of 25 horsepower, in addition to which batteries are employed. We may mention that the whole of the work (excavating, building engine-house, &c.) had to be undertaken by the electricians, and the result is a very neat and compact station.

**Edison Underground Work.**—The Edison Company of Boston has two stations supplying 32,000 incandescence lamps and 50 Ward arc lights, with a motive power of 1,400 H.P. The underground system has an extension of two miles, with 40 miles of feeders and mains. The longest feeder is about 6,000 feet. Railway bridges are crossed by means of a Clark specially prepared cable, pulled through a 3-inch gas pipe. The crossing to South Boston will be made by an armoured Clark submarine cable.

**Electricity in a Silver Mine.**—Since the introduction of electric machinery of the Westinghouse manufacture into several Pennsylvania coal mines, the demand for that company's apparatus is rapidly increasing. The Westinghouse Company is now engaged in manufacturing power apparatus for the operation of a silver mine owned by the Gold King Mining Company of Telluride, Colo., L. A. Munn of that city being the president of the company. The mine in question is situated on the top of a mountain about 2,000 feet high, and as the cost of coal is a great factor in the operation of a mine under such circumstances, the advantages of electric power over steam can be easily appreciated.

**The Priority of the Electrical Gyroscope.**—M. Dumoulin-Froment claims against M. Trouvé the invention of the electrical gyroscope. It appears that the gyroscope was invented by Foucault in 1850, and in 1867 M. Froment showed in the Champs de Mars Palace an instrument worked by electrical mechanism, whilst M. Trouvé only presented his to the Académie des Sciences in September last. Our readers may recollect that we gave an illustrated description of an electrical gyroscope devised by Mr. G. M. Hopkins in our issue for August 15th, 1878.

## OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Brush Electrical Engineering Company, Limited.**—The annual return of this company, made up to the 22nd September, was filed on the 12th inst. The nominal capital is £750,000 divided into 150,000 ordinary shares of £3 each and 150,000 preference shares of £2 each. The shares taken are 76,978 ordinary and 68,996 preference shares, and upon 68,914 of the former and 68,914 of the latter the sum of £344,570 is considered as paid up. The full amount has been called upon the remaining shares, the total of the calls paid amounting to £24,353 10s. and unpaid £2 10s.

## NEW COMPANIES REGISTERED.

**Electricity and Electrical Engineering Newspaper Company, Limited.**—Capital £500, in £10 shares. Objects: To establish and work a newspaper devoted to the interests of electrical science in all its branches. Signatories (with 1 share each): Wm. Swan Sonnen-

schein, 62, Russell Square; H. Wigham, Uplands, East Sheen; R. Oswald Smith, 73, Eaton Square; F. C. Tilney, 126, Corbyn Street, Stroud Green; Julius Maier, Ph.D., 23, Melrose Gardens, S.W.; F. D. Summers, 13, Oberstein Road, Wandsworth; George Newnes, M.P., Wildcroft, Putney Heath. Registered, without special articles of association, by Bowman and Co., 21, Bedford Row. Registered office, 6, White Hart Street, Paternoster Square.

**Chagford and Devon Electric Light Company, Limited.**—Capital £2,000 in £1 shares. Objects: To carry out an agreement of 12th inst. for supplying electric light to Chagford, Devon. Signatories: J. Collins, F. Aggett, J. Underhill, L. Holmes, J. Smith, 1 share each; G. H. Reed (engineer), 5 shares, all of Chagford, Devon; E. Eaton, C.E., M.S.A., 27, Martin's Lane, London, E.C., 1 share. Registered 18th inst., without special articles of association, by J. Fleming, 27, Martin's Lane, E.C.

**Anglo-Mexican Saw Mills Company, Limited.**—Capital £5,000, in £1 shares. Objects: To carry on in Mexico the business of saw mill proprietors, and to acquire all necessary rights of using steam, electricity, or water power in connection therewith, and particularly to manufacture cigar boxes; to acquire and deal with patent machinery, apparatus and materials for the production and distribution of electricity. Signatories (with 1 share each), H. S. Sugden, Stroud Green, N.; F. H. Depree, 21, George Street, Portman Square; T. Seabrook, 126, Stanstead Road, Forest Hill; W. Hart, 27, Sandover Road, Camberwell; G. H. Lovell, Manor Road Leyton; A. Allwork, 229, Tufnell Park Road, N. The signatories are to appoint the first directors. Qualification, 10 shares. The company, in general meeting, will determine remuneration. Registered 14th. Solicitor, Mr. James Curtis, 1, Old Jewry Chambers.

**Ernest Scott and Mountain, Limited.**—Capital, £70,000 in £10 shares. Objects: To carry on business as electrical and general engineers. Signatories (with 1 share each): P. W. Bullock, 19, Portsea Place, Connaught Square; J. Aspinall, 34, Bourvan's Buildings, Edgware Road; J. McNab, Drapers' Gardens; W. Capel Slaughter, 21, Great Winchester Street; D. Scott, 12, York Street, Manchester; A. H. Bartlett, 21, Great Winchester Street; S. E. Preston, 21, Great Winchester Street. The signatories are to appoint the first directors; qualification, £1,000 in shares; remuneration, £200 per annum to each ordinary director. Registered 17th inst. by Slaughter and May, 21, Great Winchester Street.

**South Molton Shirt and Collar Manufacturing Company, Limited.**—Capital £5,000 in £10 shares. Objects: To manufacture shirts, collars and cuffs. To act as undertakers for the supply of electricity for lighting and other purposes. Signatories: W. J. Redler, Taunton, 35 shares; W. C. Rafarel, Barnstaple, 20 shares; D. J. C. Bush, South Molton, 10 shares; G. H. Crocker, South Molton, 10 shares; J. T. B. White, South Molton, 5 shares; D. B. Redler, Taunton, 5 shares; G. Bush, 34, Cleveland Square, Hyde Park, 10 shares. The signatories are to nominate the first directors; qualification £50 in shares. Registered 17th inst. by Riccard and Son, South Molton, North Devon.

**Electrolytic Syndicate, Limited.**—Capital £100,000, in £1 shares. Objects: To adopt the following agreements, particulars of which are not specified, viz.:—An agreement of 25th ult., between Wm. Elmore and Alfred Wells; an agreement of 24th ult., between Arthur Cooper and Alfred Wells; an agreement of 25th ult., between John Fraser and Alfred Wells; an agreement of 23rd ult., between Woodhouse and Rawson United, Limited, of the first part, Wm. Elmore, Frank Elmore, and Alexander Stanley Elmore, of the second part, and Alfred Wells, of the third part. To carry on business as miners, metallurgists, smelters, and electricians. Signatories (with 1 share each): J. Jepson Atkinson, Cosgrave Priory, North Hants; W. Elmore,

47, Clapham Road ; J. Thompson Cooper, Nightingale Lane, S.W. ; F. Safford, 2, Garden Court, Temple ; S. Evans, Lonsdale Chambers, Chancery Lane ; W. J. H. Tippet, 11, Maiden Lane ; W. J. Peck, Redcar. Registered 17th inst., without articles by the Metropolitan Provisional Syndicate, Limited, 27, Chancery Lane.

## CITY NOTES, REPORTS, MEETINGS, &c.

### The Swan United Electric Light Company, Limited.

THE eighth annual report of the directors, to be presented at the ordinary general meeting of the company next Tuesday, states that after paying all current charges, and making due allowance for depreciation, there is a credit balance of £44,477 15s. 10d. The directors recommend that out of this balance a dividend of 10 per cent. for the year be declared; an interim dividend at the rate of 6 per cent. per annum, amounting to £11,104 0s. 5d., has already been paid in respect to the first half of the year; the balance of the 10 per cent. for the entire year to be distributed in accordance with clause 77 of the articles of association, and to be payable on the 1st December next. This will absorb £24,921 17s. 7d., and leave £8,451 17s. 10d. to be carried forward.

The decision in the patent suit in Germany was given in favour of this company in the Court of Appeal in Berlin during the summer. The Allgemeine Electricitäts Gesellschaft have appealed from that decision to the Supreme Court at Leipzig. It is expected that the case will be heard and finally decided before Christmas.

The Compagnie Générale des Lampes Incandescentes in Paris have not yet been able to obtain a decision in the courts on the validity of their French patents, but they think that the case will be reached and a decision given during next spring. Their business is increasing, but the competition which they have to sustain compels them to sell lamps at a lower price than heretofore.

The directors who retire by rotation are F. R. Leyland, Esq., and W. C. Quilter, Esq., M.P., who, being eligible, will offer themselves for re-election.

Messrs. Welton, Jones & Co., the auditors, will also retire, and will offer themselves for re-election.

### The Allgemeine Electricitäts-Gesellschaft.

A REPORT and balance-sheet for the financial year 1889-90 has just been issued, which will be presented to the general meeting on the 29th inst. The document before us reveals a most satisfactory state of affairs of this company, which has been in existence for about eight years, and which may be regarded as the most prosperous concern of the kind in Europe.

The sales of electrical supplies reached the large figure of £550,000, as against £300,000 during the previous year, an increase in trade of over 45 per cent. The company employs a staff of 400 officials and 1,600 workmen. In view of this enormous development of business, it was decided to increase the capital from £800,000 to £1,000,000 (20 marks taken as equivalent to £1). The company has recently acquired the Sprague system of electric traction, which is now being put into operation on the Halle tramways. Among other industrial undertakings in which the Allgemeine Electricitäts-Gesellschaft is largely interested, may be mentioned the works of Messrs. Muller and Einbeck, where the accumulators of Tudor are being manufactured; a considerable share in the Edison General Electric Company of New York; the large brass foundry of Messrs. J. C. Spinn and Son, of Berlin; the Berlin Elektricitäts-Werke (central station); the Compagnie Internationale d'Electricité de Liège; the Aluminium Company at Neuhausen; the Key's Electric Company, Limited, of London; the Syndicate for Exploitation of the Waterpower of the River Rhine; the Compania General Madrilená de Electricidad, Madrid (central station, with 20,000 lamps).

Among the patents which this company has purchased from time to time are those of Maxim-Weston, Sprague and Edison, in addition to a large number of Continental ones. The cost of these has been written off year after year, and this item is now credited in the balance-sheet with one shilling; the sum written off last year amounting to £5,366.

The net trading profits of 1889-90 stand at £63,639, against £39,573 last year, but the net profits from all sources reached the respectable total of £113,101, which will be distributed as follows:

Returnable ... ..	£7,500
Extraordinary reserve ... ..	12,500
10 per cent. dividend on £800,000 ... ..	80,000
Board of directors ... ..	8,000
Sick fund and pensions ... ..	4,000
Carried forward, 1890-91 ... ..	1,101

£113,101

The company proposes to take part in the next Frankfurt Exhibition in a peculiar way; it intends to transmit to this city

300 H.P. of a waterfall 110 miles distant, the work to be carried out in conjunction with the Oerlikon Fabrik.

This is one of the most interesting reports to shareholders we have yet seen.

### Blackpool Electric Tramway Company, Limited.

IN the report to be presented at the sixth annual general meeting, to be held to-morrow (Saturday), the directors state that they have pleasure in submitting to the shareholders their sixth report and the accompanying statement of the accounts of the company for the year ending 31st October, 1890.

The revenue account shows a balance in hand for the year of £2,455 9s. 3d. Adding to this £231 5s. 10½d. from last year, makes an available amount of £2,686 15s. 1½d., of which the directors recommend the following disposal:—

	£	s.	d.
Dividend of 7½ per cent. on the called up share capital, free of tax ... ..	1,501	17	6
Depreciation and reserve fund ... ..	1,000	0	0
Balance to next year's account ... ..	184	17	7½
	£2,686	15	1½

The depreciation and reserve fund, with the addition of £1,000 as above recommended, will be £4,418 15s. 1d.

The number of passengers carried this year was 812,299. The number of miles run during the year was about 92,000.

The retiring directors are Messrs. Ormerod, Shaw and Smith, who are eligible for re-election.

Mr. Broadbent's services as managing director have been secured again for the coming year.

The transfer books of the company will be closed from the 13th to the 22nd November, inclusively.

### Eastern Extension Telegraph Company.

SIR JOHN PENDER presided on Wednesday afternoon at the offices, Winchester House, Old Broad Street, over an extraordinary general meeting of the shareholders of the Eastern Extension, Australasia, and China Telegraph Company, Limited.

The Chairman proposed the confirmation of the resolution passed at the meeting on the 22nd ult., and given in our issue of October 24th, for authorising the board from time to time to create and issue mortgage debenture stock of the company to an amount not exceeding one-third of the share capital for the time being issued and paid up, the stock to rank *pari passu* as a first charge on the undertaking and revenue of the company. The object of the meeting was, he said, to enable the directors to replace the £320,000 of 6 per cent. debentures by an issue of 4 per cent. debenture stock. This would effect a saving of £6,000 a year to the company.

The Marquis of Tweeddale seconded the motion.

Replying to questions, the Chairman said that they proposed to take 5 per cent. on application, 5 per cent. on allotment, and 90 per cent. on the 15th January. The 1st of February was the day on which they would be obliged to have the money ready to redeem the 6 per cent. bonds.

The motion was unanimously confirmed.

The Chairman afterwards observed that the present was rather an unfortunate time for the operation, but he thought they might congratulate themselves upon the fact that during all the existing exceptionally severe crisis their stocks had not varied ¼ per cent. Their proprietary, however, was one which was pretty free from Stock Exchange difficulties—persons having homes and dependent on small incomes, and who were able to appreciate steady and regular dividends.

A vote of thanks to the chairman closed the meeting.

**Paris Edison Company.**—The Edison Company of Paris, which has a share capital of 10 million francs, made a gross profit of 1,082,922 francs for the year 1889-90, and a net profit of 350,264 francs. A dividend of 22½ francs was declared on the original shares, and 4½ francs on the new shares.

**The Electric Construction Corporation, Limited.**—Subject to final audit, the directors of the above company have decided to declare a dividend of 6 per cent. per annum upon the ordinary share capital of the corporation for the past year.

**Elmore's Foreign and Colonial Patent Copper Depositing Company, Limited.**—The transfer books will be closed from December 1st to December 8th inclusive, for the purpose of paying a dividend.

### TRAFFIC RECEIPTS.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending November 14th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £4,087.

The Brazilian Submarine Telegraph Company, Limited. The traffic receipts for the week ending November 14th were £5,249.

## LATEST PROCURABLE QUOTATIONS OF SECURITIES NOT OFFICIALLY QUOTED.

Blackpool Electric Tramway Company, Limited, £10 (£6½ paid), 7½—7½.—Elmore Copper Depositing Priorities, 7—7½.—Elmore's French Patent Copper Depositing shares of £2 (issued at 10s. premium, 15s. paid), 2—2½.—House-to-House Company (£5 paid), 4½—5½.—London Electric Supply Corporation, Ordinary (£5 paid), 2½—2½.—Manchester Edison and Swan Company, £3 (£1 paid) 11/-—13/-.—Woodhouse & Rawson Ordinary of £5 (£2 10s. paid), 2½—3.—Preference, 4½—4½.

BANK RATE OF DISCOUNT.—6 per cent. (7th November 1890).

## THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.

(Continued from page 603.)

LECTURE III.—DELIVERED FEBRUARY 3RD, 1890.

## SPECIAL DESIGNS.

In continuation of my lecture of last week, I have to make a few remarks before entering upon the consideration of special forms of magnets, which was to form the entire topic of to-night's lecture. I had not quite finished the experimental results which related to the performance of magnets under various conditions. I had already pointed out that where you require a magnet simply for holding on to its armature, common sense (in the form of our simplest formula) dictated that the circuit of iron should be as short as was compatible with getting the required amount of winding upon it. That at once brings us to the question of the difference in performance of long magnets and short ones. Last week we treated that topic so far as this, that if you require your magnet to attract over any range across an air space, you required a sufficient amount of exciting power in the circulation of electric current to force the magnetic lines across that resistance, and therefore you required length of core in order to get the required coil wound upon the magnetic circuit. But there is one other way in which the difference of behaviour between long and short magnets—I am speaking of horse-shoe shapes—comes into play. So far back as 1840, Ritchie found that it was more difficult to magnetise steel magnets (using for that purpose electro-magnets to stroke them with) if those electro-magnets were short than if they were long. He was, of course, comparing magnets which had the same tractive power, that is to say, presumably had the same section of iron magnetised up to the same degree of magnetisation. This difference between long and short cores is obviously to be explained on the same principle as the greater projecting power of the long-legged magnets. In order to force magnetism not only through an iron arch but through whatever is beyond, which has a lesser permeability for magnetism, whether it be an air gap or an arch of hard steel destined to retain some of its magnetism, you require magnetomotive force enough to drive the magnetism through that resisting medium; and, therefore, you must have turns of wire; that implies that you must have length of leg on which to wind those turns. Ritchie also found that the amount of magnetism remaining behind in the soft iron arch, after turning off the current, at the first removal of the armature, was a little greater with long than with short magnets; and, indeed, it is what we should expect now, knowing the properties of iron, that long pieces, however soft, retain a little more—have a little more memory, as it were, of having been magnetised—than short pieces. Later on I shall have specially to draw your attention to the behaviour of short pieces of iron which have no magnetic memory.

## WINDING OF THE COPPER.

I now take up the question of winding the copper wire upon the electro-magnet. How are we to determine beforehand the amount of wire required, and the proper gauge of wire to employ?

The first stage of such a determination is already accomplished; we are already in possession of the formulæ for reckoning out the number of ampère turns of excitation required in any given case. It remains to show how from this to calculate the amount of bobbin space, and the quantity of wire to fill it. Bear in mind that a current of ten ampères (i.e., as strong as that used for a big arc light) flowing once around the iron, produces exactly the same effect magnetically as a current of one ampère flowing around ten times or as a current of only one-hundredth part of an ampère flowing around a thousand times. In telegraphic work the currents ordinarily used in the lines are quite small, usually from five to twenty thousandths of an ampère; hence in such cases the wire that is wound on need only be a thin one, but it must have a great many turns. Because it is thin and has a great many turns, and is consequently a long wire, it will offer a considerable resistance. That is no advantage, but does not necessarily imply any greater waste of energy than if a thicker coil of fewer turns were used with a correspondingly larger current. Consider a very simple case. Suppose a bobbin is already filled with a certain number of turns of wire, say 100, of a size large enough to carry one ampère, without over-heating. It will offer a certain resistance, it will waste a certain amount of the energy of the current, and it will have a certain magnetising power. Now suppose this bobbin to be re-wound with a wire of half the diameter; what will the result be? If the wire is half the diameter it will have one quarter the sectional area, and the bobbin will hold four times as many turns (assuming insulating materials to occupy the same percentage of the available volume). The current which such a wire will carry will be one-fourth as great. The coil will offer sixteen times as much resistance, being four times as long and of one-fourth the cross section as the other wire. But the waste of energy will be the same, being proportional to the resistance and to the square of the current; for  $16 \times \frac{1}{16} = 1$ . Consequently the heating effect will be the same. Also the magnetising power will be the same, for though the current is only one-quarter of an ampère, it flows around four hundred turns;

the ampère turns are one hundred, the same as before. The same argument would hold good with any other numerical instance that might be given. It therefore does not matter in the least to the magnetic behaviour of the electromagnet whether it is wound with thick wire or thin wire, provided the thickness of the wire corresponds to the current it has to carry, so that the same number of watts of power are spent in heating it. For a coil wound on a bobbin of given volume the magnetising power is the same for the same heat waste. But the heat waste increases in a greater ratio than the magnetising power, if the current in a given coil is increased; for the heat is proportional to the square of the current and the magnetising power is simply proportional to the current. Hence it is the heating effect which in reality determines the winding of the wire. We must—assuming that the current will have a certain strength—allow enough volume to admit of our getting the requisite number of ampère turns without overheating. A good way is to assume a current of one ampère while one calculates out the coil. Having done this, the same volume holds good for any other gauge of wire appropriate to any other current. The terms "long-coil" magnet and "short-coil" magnet are appropriate for those electromagnets which have, respectively, many turns of thin wire and few turns of thick wire. These terms are preferable to "high resistance" and "low resistance," sometimes used to designate the two classes of windings, because, as I have just shown, the resistance of a coil has in itself nothing to do with its magnetising power. Given the volume occupied by the copper, then for any current density (say, for example, a current density of 2,000 ampères per square inch of cross section of the copper), the magnetising power of the coil will be the same for all different gauges of wire. The specific conductivity of the copper itself is of importance; for the better the conductivity, the less the heat waste per cubic inch of winding. High conductivity copper is therefore to be preferred in every case.

Now the heat which is thus generated by the current of electricity raises the temperature of the coil (and of the core), and it begins to emit heat from its surface. It may be taken as a sufficient approximation that a single square inch of surface, warmed  $1^{\circ}$  Fahr. above the surrounding air, will steadily emit heat at the rate of  $\frac{1}{255}$  of a watt. Or, if there is provided only enough surface to allow of a steady emission of heat at the rate of 1 watt\* per sq. inch of surface, the temperature of that surface will rise to about  $225^{\circ}$  Fahr. above the temperature of the surrounding air. This number is determined by the average emissivity of such substances as cotton, silk, varnish, and other materials of which the surfaces of coils are usually composed.

In the specifications for dynamo machines, it is usual to lay down a condition that the coils shall not heat more than a certain number of degrees warmer than the air. With electro-magnets it is a safe rule to say that no electro-magnet ought ever to heat up to a temperature more than  $100^{\circ}$  Fahr. above the surrounding air. In many cases it is quite safe to exceed this limit.

The resistance of the insulated copper wire on a bobbin may be approximately calculated by the following rule. If  $d$  is the diameter of the naked wire, in mills, and  $D$  is the diameter, in mills, of the wire when covered, then the resistance per cubic inch of the coil will be:—

$$\text{Ohms per cub. inch} = \frac{960,700}{D^2 + d^2}$$

We are therefore able to construct a wire gauge and ampère table which will enable us to calculate readily the degree to which a given coil will warm when traversed by a given current, or conversely what volume of coil will be needed to provide the requisite circulation of current without warming beyond any prescribed excess.

Accordingly, I here give a *Wire-Gauge and Ampère Table*, which we have been using for some time at the Finsbury Technical College. It was calculated out under my instructions by one of the Demonstrators of the College, Mr. Eustace Thomas, to whom I am indebted for the great care bestowed upon the calculations.

For many purposes, such as for use in telegraphs and electric bells, smaller wires than any of those mentioned in the table are required. The table is, in fact, intended for use in calculating magnets in larger engineering work.

A rough and ready rule sometimes given for the size of wire is to allow  $\frac{1}{1000}$  square inch per ampère. This is an absurd rule, however, as the figures in the table show. Under the heading 1,000 ampères to square inch, it appears that if a No. 18 S.W.G. wire is used, it will at that rate carry 1.81 ampères; that if there is only one layer of wire, it will only warm up  $4.64^{\circ}$  Fahr., consequently one might wind layer after layer to a depth of 3.3 inches, without getting up to the limit of allowing one square inch per watt, for the emission of heat. In very few cases does one want

\* The watt is the unit of rate of expenditure of energy, and is equal to ten million ergs per second, or to  $\frac{1}{746}$ th of a horse-power. A current of one ampère, flowing through a resistance of one ohm, spends energy in heating at the rate of one watt. One watt is equivalent to 4.2 calories per second, of heat. That is to say, the heat developed in one second, by expenditure of energy at the rate of one watt, would suffice to warm one gramme of water through  $4.2$  (Centigrade) degrees. As 252 calories are equal to one British (lb. Fahrenheit) unit of heat, it follows that heat emitted at the rate of one watt would suffice to warm  $17\frac{1}{2}$  pounds of water one degree Fahrenheit in one minute; or one British unit of heat equals 1,058 watt-seconds.

\* Cantor Lecture. Delivered before the Society of Arts, January 27th, 1890.

TABLE X.—WIRE GAUGE AND AMPERAGE TABLE.

Dimensions.					Permissible ampère, probable heating, and permissible depth.

Figures in columns marked A signify number of ampères that the wire carries.

Figures in columns marked F signify number of degrees (Fahr.) that the coil will warm up if there is only one layer of wire, and on the assumption that the heat is radiated only from the outer surface of the coil: they are calculated by the following modification of Forbes's rule:—

Rise in temperature (Fahrenheit degrees)

=  $225 \times \text{No. of watts lost per sq. inch.}$

=  $159 \times \text{sectional area} \times \text{number of turns to 1 inch (at 1,000 amps. per sq. inch.)}$

Figures in columns marked D are the depths in inches to which wire may be wound if one watt be lost by each square inch of radiating surface, the outside radiating surface of the bobbin being only considered.

Rule for calculating a 7-strand cable:—Diam. of cable =  $1 \cdot 134 \times \text{by diam. of equivalent round wire.}$

Figures under heading "Turns to 1 linear inch" are calculated for cotton-covered wires of average thicknesses of coverings used for the different gauges, viz., 14 mils additional diameter on round wires (from No. 22), and 20 mils on stranded or square wire.

Figures under heading "Turns per sq. inch" are calculated from preceding, allowing 10 per cent. for bedding of layers.

Resistance (ohms) of coil of copper wire, occupying  $v$  cubic inches of coil-space, and of which the gauge is  $d$  mils uncovered, and  $D$  mils covered, may be approximately calculated by the rule:—

$$\text{ohms} = 960,700 \frac{v}{D^2 d^2}$$

The data respecting sizes of wires of various gauges are kindly furnished by the London Electric Wire Company.

to wind a coil so thick as 3·3 inches. For very few electro-magnets is it needful that the layer of coil should exceed  $\frac{1}{2}$  an inch in thickness; and if the layer is going to be only  $\frac{1}{2}$  an inch thick, or about  $\frac{1}{3}$ th of the 3·3, one may use a current density  $\sqrt{7}$  times as great as 1,000 ampères per square inch, without exceeding the limit of safe working. Indeed, with coils only  $\frac{1}{2}$  inch thick, one may safely employ a current density of 3,000 ampères per square inch, owing to the assistance which the core gives for the dissipation and emission of heat.

Suppose, then, we have designed a horse-shoe magnet, with a core 1 inch in diameter, and that after considering the work it has to do, it is found that a magnetising power of 2,400 turns is required; suppose, also, that it is laid down as a condition that the coil must not warm up more than 50° Fahr. above the surrounding air—what volume of coil will be required? Assume first that the current will be 1 ampère; then there will have to be 2,400 turns of a wire which will carry 1 ampère. If we took a No. 20 S.W.G. wire, and wound it to a depth of  $\frac{1}{2}$  an inch, that would give 220 turns per inch length of coil: so that a coil 11 inches long, and a little over  $\frac{1}{2}$  inch deep (or 10 layers deep) would give 2,400 turns. Now Table X. shows that if this wire were to carry 1·018 ampère, it would heat up 225° Fahr., if wound to a depth of 3·9 inches. If wound to  $\frac{1}{2}$  inch, it would therefore heat up about 30° Fahr.; and with only 1 ampère would of course heat less. This is too good; try the next thinner wire. No. 22, S.W.G. wire, at 2,000 ampères to square inch, will carry 1·23 ampères; and heats 225° if wound up 1·13 inches. If it is only to heat 50° it must not be wound more than  $\frac{1}{2}$  inch deep; but if it only carries current of 1 ampère it may be wound a little deeper—say to 14 layers. There will then be wanted a coil about 7 inches long to hold the 2,400 turns. The wire will occupy about 3·85 square inches of total cross section; and the volume of the space occupied by the winding will be 26·95 cubic inches. Two bobbins, each 3 $\frac{1}{4}$  inches long and ·65 deep, to allow for 14 layers, will be suitable to receive the coils.

By the light of the knowledge one possesses as to the relation between emissivity of surface, rate of heating by current, and limiting temperatures, it is seen how little justification there is for such empirical rules as that which is often given, namely, to make the depth of coil equal to the diameter of the iron core. Consider this in relation to the following fact; that in all those

cases where leakage is negligible, the number of ampère turns that will magnetise up a thin core to any prescribed degree of magnetisation will magnetise up a core of any section whatever, and of the same length, to the same degree of magnetisation. A rule that would increase the depth of copper proportionately to the diameter of the iron core is absurd.

Where less accurate approximations are all that is needed, more simple rules can be given. Here are two cases:—

Case 1. Leakage assumed to be negligible.—Assume  $B = 16,000$ , then  $H = 50$  (see Table III). Hence the ampère turns per centim. of iron will have to be 40, or per inch of iron, 102; for  $H$  is equal to 1·2566 times the ampère turns per centimetre. Now if the winding is not going to exceed  $\frac{1}{2}$ -inch in depth, we may allow 4,000 ampères per square inch without serious overheating. And the 4,000 ampère turns will require 2-inch length of coil, or each inch of coil carries 2,000 ampère turns without overheating. Hence each inch of coil  $\frac{1}{2}$ -inch deep will suffice to magnetise up 20 inches length of iron to the prescribed degree.

Case 2. Leakage assumed to be 50 per cent.—Assume  $B$  in air gap =  $H = 8,000$ , then to force this across requires ampère turns 6,400 per centim. of air, or 16,250 per inch of air. Now if winding is not going to exceed  $\frac{1}{2}$ -inch depth, each inch length of coil will carry 2,000 ampère turns. Hence, 8 inches length of coil  $\frac{1}{2}$ -inch deep will be required for one inch length of air, magnetised up to the prescribed degree.

#### WINDINGS FOR CONSTANT PRESSURE AND FOR CONSTANT CURRENT.

In winding coils for magnets that are to be used on any electric light system, it should be carefully borne in mind that there are separate rules to be considered according to the nature of the supply. If the electric supply is at constant pressure, as usual for glow lamps, the winding of coils of electro-magnets follows the same rule as the coils of voltmeters. If the supply is with constant current, as usual for arc lighting in series, then the coils must be wound with due regard to the current which the wire will carry, when lying in layers of suitable thickness, the number of turns being in this case the same whether thin or thick wire is used.

If we assume that a safe limit of temperature is 90° Fahr. higher than the surrounding air, then the largest current which

may be used with a given electro-magnet is expressed by the formula:—

$$\text{Highest permissible ampères} = 0.63 \sqrt{\frac{s}{r}}$$

where  $s$  is the number of square inches of surface of the coils, and  $r$  their resistance in ohms.

Similarly for coils to be used as shunts we have:—

$$\text{Highest permissible volts} = 0.63 \sqrt{sr}$$

The magnetising power of a coil, supplied at a given number of volts of pressure, is independent of its length, and depends only on its gauge, but the longer the wire the less will be the heat waste. On the contrary, when the condition of supply is with a constant number of ampères of current, the magnetising power of a coil is independent of the gauge of the wire, and depends only on its length; but the larger the gauge the less will be the heat waste.

#### MISCELLANEOUS RULES ABOUT WINDING.

To reach the same limiting temperature with bobbins of equal size wound with wires of different gauge, the cross-section of the wire must vary with the current it is to carry; or, in other words, the current density (ampères per square inch) must be the same in each. Table X. shows the ampérages of the various sizes of wires, at four different values of current density.

To raise to the same temperature two similarly shaped coils, differing in size only, and having the gauges of the wires in the same ratio (so that there are the same number of turns on the large coil as on the small one), the currents must be proportional to the square roots of the cubes of the linear dimensions.

Sir William Thomson has given a useful rule for calculating windings of electro-magnets of the same type but of different sizes. Similar iron cores, similarly wound with lengths of wire proportional to the squares of their linear dimensions, will, when excited with equal currents, produce equal intensities of magnetic field at points similarly situated with respect to them.

Similar electro-magnets of different sizes must have ampère-turns proportional to their linear dimensions if they are to be magnetised up to an equal degree of saturation.

It is curious what erroneous notions crop up from time to time about winding electro-magnets. In 1869, a certain Mr. Lyttle took out a patent for winding the coils in the following way. Wind the first layer as usual, then bring the wire back to the end where the winding began and wind a second layer, and so on. In this way all the windings will be right-handed, or else all left-handed, not alternately right and left as in the ordinary winding. Lyttle declared that this method of winding a coil gave more powerful effects; so did M. Brisson, who re-invented the same mode of winding in 1873, and solemnly described it. Its alleged superiority was at once disproved by Mr. W. H. Preece, who found the only difference to be that there was more difficulty in carrying out this mode of winding.

Another popular error is that electro-magnets in which the wires are badly insulated are more powerful than those in which they are well insulated. This arose from the ignorant use of electro-magnets having long thin coils (of high resistance) with batteries consisting of a few cells (of low electromotive force). In such cases, if some of the coils are short-circuited, more current flows, and the magnetising power may be greater. But the scientific cure is either to rewind the magnet with an appropriate coil of thick wire, or else to apply another battery having an electromotive force that is greater.

(To be continued.)

#### NEW PATENTS—1890.

17165. "A process for producing copper blocks with steel core for the manufacture of telegraph and telephone wire." H. LOHAUSEN. Dated October 27.

17181. "Improved electric switch." H. J. ALLISON. (Communicated by J. A. K. McGregor, H. Wallach, and S. J. Wallach, United States.) Dated October 28. (Complete.)

17247. "Improvements in electric apparatus for transmitting motion." M. W. DEWEY. Dated October 28. (Complete.)

17277. "An improved method of and apparatus for the electrical treatment of sewage, wines, oils, air, gases, and other fluids." R. WOTHERSPOON. (Communicated by H. Rowley, Australia.) Dated October 29.

17308. "Improved switch for electric light." C. W. COX and F. ROBINSON. Dated October 29.

17375. "An electric motor." J. B. DENIS. Dated October 30.

17394. "Apparatus for effecting a permanent make or break of an electric circuit at any suitable number of points." L. V. CHABRAND. Dated October 30.

17459. "Improvements in and relating to electric arc lamps." F. V. MAQUAIRE. Dated October 31.

17558. "Portable generator and electrometer for testing insulation resistance of electric wires." J. J. RATHBONE. Dated November 1.

17560. "Improvements in and relating to locked switches for electric current circuits." J. A. ILIFFE and H. BARTON. Dated November 1.

#### ABSTRACTS

#### OF PUBLISHED SPECIFICATIONS 1889.

14860. "Improvements in automatic telephone devices." C. G. HOFFMANN. Dated September 20. 11d. Consists in the main of the speaking apparatus, of the mechanism for examining the coin and of the box, and consists in the combination of a telephone system with a coin examining apparatus and a clock mechanism situated in the exchange station in such a manner, that by the insertion of a certain coin into the apparatus a draw rod is released and by pulling the same by means of lever connections the telephones are liberated so that a call is automatically effected to the exchange station, which establishes the desired connection with the public speaking station which is then connected with the wire of the subscriber by the pressure of a button and at the same time causing the stoppage of a wheel moved by a clock mechanism during any desired interval (5 minutes) by a lever which at the termination of this time, raised by another lever, establishes again the earth connection and thus interrupts automatically the connection of the public speaking station with the subscriber. 6 claims.

15609. "Improved electrical railway switch and signal apparatus." F. X. BACHMANN. Dated October 4. 8d. Includes a system of signals electrically operated in conjunction with the points from the same station. 4 claims.

17124. "Improvements in interrupting devices for electric circuits, applicable for protecting electrical apparatus connected in such circuits." W. P. THOMPSON. (A communication from abroad by the Westinghouse Electric Company of America.) Dated October 29. 8d. Consists in forming a shunt circuit around a fusible strip, so constructed as to receive the entire current immediately upon the destruction of the fusible strip and then itself become interrupted in such a manner as to form an opening of the circuit. 3 claims.

17274. "An electric switch." G. S. GRIMSTON. (Partly communicated from abroad by F. Jacob.) Dated October 31. 6d. The inventor provides a ratchet wheel having an even number of teeth, which are alternately of conducting and of insulating material or are faced with such material, all the conducting parts being connected to the one wire of the circuit. A metallic spring pawl which is connected to the other wire of the circuit bears against the ratchet wheel, which is otherwise insulated from the pawl. On turning the wheel by hand partly round the pawl is first strained against its spring and then jumps rapidly from one tooth to the next, making or breaking contact as the case may be, and then holding the wheel steadily in position and preventing it from being turned backwards. 1 claim.

17694. "An electrical watt meter." E. WILSON. Dated November 6. 8d. The inventor applies an automatic break solenoid, excited by the current or a known fraction thereof, to give reciprocation to an anchor acting on an escapement wheel to cause a spindle to revolve at a speed which is proportional to the electromotive force or volts of the exciting current. The spindle drives a disc or cone, and also by means of a bevil wheel drives two opposite bevil pinions which are free on a transverse spindle, but either of which can be clutched to the transverse spindle by a clutch sleeve sliding between them. This clutch sleeve is connected to an armature between two electro-magnets, or to the core of a solenoid subject to the strain of a spring, so that according as the one or the other of the two electro-magnets is excited or according as the solenoid is excited or not, the clutch is moved so as to engage the one or the other of the two bevil pinions to the transverse spindle, causing that spindle to rotate in the one direction or the other. 2 claims.

17831. "Improvements in electric battery carbon and carbon compound elements and their connections." J. V. SHERRIN. Dated November 8. 6d. The inventor connects and prepares the carbon or carbon compound elements for primary and other electric batteries in the following manner: In that part of the upper edge of the carbon where the connection is to be made he laps it round with a piece of sheet platinum or platinum foil upon which he places a brass clamp or other connection for the wire. The clamp may be fixed by means of a screw the point of which bears on an interposed copper plate. To the clamp he connects the wire by soldering or by a terminal screw. The upper part of the carbon element is then covered with shellac to a depth of about an inch or two down from the top. 3 claims.

18159. "Improvements in electric contact apparatus, chiefly designed for indicating the level of water in reservoirs, the movement of hauling drums, lifts, and the like." C. WEUSTE. Dated November 13. 8d. Comprises a disc having in or upon it one or more teeth, which disc is in the first place caused to turn by the float of a water reservoir or by the machine or other device to be controlled. By this means a pin, acted upon by a weight or a comparatively heavy ball, is carried away. As soon as the aforesaid tooth has been turned far enough it releases the ball or the pin whereupon the latter by reason of its weight or the action of the spring will move upon a suitable guide back to its original position, making contact at the same time. 2 claims.

18980. "Improved means of suspending electric lamps and other suspended objects." W. F. BEADNEE. Dated November 26. 8d. Consists in the interposition, in the suspension cord or cable, of a differential pulley, windlass, or drum having peripheries of

two diameters, from one of which the cable extends to the ceiling or other point of support, and from the other of which the cord or cable descends to the lamp, the differential pulley (with or without a case) forming a weight which, when the lamp is lifted, gravitates, and in unrolling the cord from the smaller pulley rolls up the slack on to the larger pulley, the balancing effect of the two pulley surfaces serving to hold the lamp at any point to which it may be adjusted. 8 claims.

19195. "Improvements in and relating to the laying of electric and other wires in streets and roads." R. SUMMERS. Dated November 29. 6d. The inventor forms the curb of the pathway hollow and of suitable material, such as cast iron, the cross section being the same as the present curb but considerably deeper. The sections are made in suitable lengths and are jointed together in any known manner. Where the wires have to cross a road, elbows are provided so as to obtain the different level between the footpath and the roadway. Openings, closed by suitable lids or doors, are provided at suitable distances apart in order to allow of easily getting at the wires and suitable connections are provided to allow of the wires being conducted to the buildings in the street or road where required. 3 claims.

## 1890.

1878. "Improvements in electric insulating compounds." J. B. WILLIAMS. Dated February 4. 6d. Consists, briefly, in the combination with India-rubber and paraffin wax of a resinous body and sulphur, to which may be added what may be designated as inert material which serves to harden the compound and lessen its cost. 5 claims.

3484. "Improved electrical secondary clockwork." E. SCHWEIZER. Dated March 4. 6d. Consists in the employment of a lever to which a reciprocating motion is imparted by the combined influence of a horizontal electro-magnet and of a spring, and which on the one hand operates by means of a pawl upon a toothed wheel on the minute arbor, and on the other hand acts by means of a rod upon a special escapement device, which in its turn acts upon the said toothed wheel, so that the number of wheels of the electrical secondary clock can be limited to that of the minute and hour wheels of an ordinary clock dial. 2 claims.

3419. "Method of and apparatus for producing and utilising pulsating electric currents in closed circuits." C. J. VAN DEPOELE. Dated March 4. 11d. Comprises means for producing electric currents having a defined rise and fall being thereby rendered intermittent or pulsating, means for varying the rate of succession of said currents, together with both rotary and reciprocating engines particularly adapted to be operated with currents produced according to my said invention, the said defined currents being moreover utilised in closed working circuits so that their characteristic qualities are not due to the use of circuit-breaking devices, upon all of which my present invention is an improvement. 5 claims.

## CORRESPONDENCE.

## Alternating Current Meters.

In your issue of October 10th, I find a letter of Mr. Arthur Wright on the subject of alternating current meters, which, on account of the writer and the contents, I cannot pass without notice. You will greatly oblige me therefore, if you will kindly insert in your columns the following few lines.

I regret that various reasons prevent me to speak without restriction on the subject as I would desire, but perhaps few words will be sufficient to show Mr. Wright that he is unacquainted with the real state of the things.

My patents—it will be remembered—appeared 1st of May, 1888, and nearly at the same time the results of Prof. Ferraris were published in *Industries*, disclosing the same invention. Once the invention was known it required but little inventive spirit to make experiments and modifications, which sooner or later must suggest themselves to every intelligent worker, and it is needless to say that the experiments referred to by Mr. Wright were performed by me at a much earlier period, and an application covering broadly the principle of operating a motor by passing an alternating current through a circuit, and inducing currents by the same in other parts or closed circuits, was filed by me long before I read my paper and showed some of my motors before the American Institute of Electrical

Engineers, in May 1888. I was, however, at that time, not at liberty to speak on this and other matters which would have rendered my paper more valuable and interesting.

Nothing was known through the journals of this invention until Schallenger's patent on the meter appeared, I believe in June, 1888, where a motor on this principle was shown in combination with a registering and retarding device. Besides some forms of motors constructed by me and based on the principle of magnetic lag and screening—which were somewhat novel features—nothing new was shown in the way of a commutatorless motor, which would not be comprised within the scope of the inventions of Prof. Ferraris, Schallenger and myself.

Mr. Wright states that I am wrong in attributing the rotation in his meter to the same cause as that in Schallenger's. I have conceived the theory of these phenomena and confirmed it by many experiments. I have been familiar with them long in advance of anything published on that subject, and have utilised the principle underlying them in many forms of practical motors; I therefore think that I am not mistaken. In Schallenger's meter a current is passed through one circuit and currents are induced in other circuits, and the poles are shifted; is not the same the case in Wright's meter? As regards the motive devices invented by Messrs. Borel and Piccaud, to which Mr. Wright refers, he makes me a high compliment, for motors on that principle were among the first which I have devised and operated, and not only have I devised many forms of these motors, but I have also shown, nearly three years ago, that in accordance with my theory of the action of the motors, a rotation in opposite direction may be produced under certain conditions.

Nikola Tesla.

November 7th, 1890.

## High-handed Proceedings.

Mr. A. Erskine Muirhead has asked us to insert the following correspondence:—

Mr. James Richmond, Baker,  
John Finnie Street, Kilmarnock.

22, Castle Street, Edinburgh,  
4th November, 1890.

SIR,—We act for the United Telephone Company of London, and have to-day received instructions to adopt proceedings against your infringing certain patent rights belonging to them. We are informed that you have recently fitted up and are using four Ader receivers, which are infringements of their patent, and our instructions are forthwith to raise an action for interdict, damages, delivery of the instruments and costs. Before doing so, we write to give you intimation of this and an opportunity of delivering up the four infringing instruments. If these are delivered to us here *complete* in the course of *to-morrow*, we shall refrain from instituting legal proceedings. If they are not, proceedings will be at once instituted without further notice.

We also beg to request you to inform us who supplied you with the instruments; and, in your own interest, to warn you against delivering them over to any one except our clients or us.

We are, your obedient Servants,

DAVIDSON & SYME.

Glasgow, 6th November, 1890.

Messrs. Davidson and Syme,  
22, Castle Street, Edinburgh.

Gentlemen,—Your favour of 4th inst., addressed to Mr. Jas. Richmond, Kilmarnock, has been handed to me, asking me to write you and also for my advice. I may at once say I take all responsibility upon myself, and when fitting up the telephones, told Mr. Richmond

that they did not infringe any of the patents held by the National Telephone Coy., Ltd., or the United Telephone Coy., Ltd.; I again assert this. The telephone in question will not be removed nor handed to you, but to show that I am more magnanimous than your clients, I am willing to allow your electric engineer, Mr. Aitken, to go with my man and inspect the telephones for himself in your client's interest.

It will help to clear the matter when I inform you that they are the English type of telephones in French cases, and this is the reason, I presume, that your zealous employés jumped to the conclusion that they were the celebrated "Ader" telephones that have given your president, Col. Jackson, and William Alexander Smith, Esq., chairman of Local Board, so much anxiety of late. I hear that your employés entered the premises of Mr. Richmond; this, if not a criminal is an illegal act, and whether the telephones are infringements or not, it will fall to your party to conciliate Mr. Richmond in any case.

Your obedient servant,

A. ERSKINE MUIRHEAD.

P.S.—The telephones have Carta (paper) diaphragms, with  $\frac{1}{4}$ " iron armatures and electro-magnets. They have no permanent magnet nor iron diaphragms.

Glasgow, 10th November, 1890.

Messrs. Davidson & Syme,  
22, Castle Street, Edinburgh.

Gentlemen,—Though I wrote you on the 6th curt., I am still without any reply from you or your clients, The National and United Telephone Company, Limited, as to what proposal they have to make regarding their unwarrantable proceedings in interfering with my telephones. I may add that I have consulted the highest authority on telephony in this country, viz., Mr. A. R. Bennett, late manager for Scotland for the National Telephone Coy., Ltd.; you can consult him also, I presume.

Yours truly,

A. E. MUIRHEAD.

Glasgow, 11th November, 1890.

Messrs. Davidson and Syme, Edinburgh.

Gentlemen,—I am still without any reply from you, and as the idea is being spread abroad by your clients, that your clients seized four "Ader" receivers infringing your client's patents, as the said four telephones belong to me, and as before explained to Mr. Alexander Smith, chairman of the Local Board of the N. T. Company, Limited, in a letter dated 4th curt., of which the following is a copy:—

"November 4th, 1890.

"Mr. W. Alex. Smith,  
"6, So. Hanover Street, Glasgow.

"Dear Sir,—I have your favour of date and am sorry you cannot accede to my request.\* I am fitting a number of 'Ader' receiver cases with Carta and English Mechanic diaphragms for exposure in Glasgow and elsewhere. I presume you are aware that those do not infringe any of your patents. I shall have pleasure in giving your engineer an order to inspect them should he think fit.

"Signed A. ERSKINE MUIRHEAD."

Mr. W. A. Smith replies on 6th as follows from Telephone Office:—

Glasgow, November 6th, 1890.

A. Erskine Muirhead, Esq.,  
Cart Forge, Glasgow.

Dear Sir,—On my return from England this morning I find your favour of 4th. As I mentioned to you for-

merly this company is determined to uphold its patents to the last day they run, and it is for you to act so that you do not infringe upon any of our rights. The question, what is or is not an infringement of our patent appliances, is one which the courts alone will decide.

Yours respectfully,

WM. ALEX. SMITH.

Up till this date you have not made any reply to my communications, you will not consider it out of order should I send a copy of this correspondence to the Press.

Yours truly,

A. E. MUIRHEAD.

P.S.—You will please note that I am running bronze wires in England and Scotland for some of the largest manufacturing firms, to which "Ader" telephones will be fixed on the expiry of the telephone patent which occurs in a few days now. To be above board with your clients, I am willing to give you a list of those lines, but repeat I will not remove the telephones in Kilmarnock.

Glasgow Offices, Royal Exchange Buildings,  
11th November, 1890.

A. Erskine Muirhead, Esq.,  
Cart Forge, Crossingloof.

Dear Sir.—Regarding yours of the 4th inst., to Mr. W. A. Smith, we have instructions from our London office for our Mr. Aitken to examine the instruments therein referred to. I will be glad therefore if you will let me know at what time it will be convenient for him to do so.

Yours truly,

F. DOUGLAS WATSON,  
Assistant District Secretary.

Glasgow, November 12th, 1890.

The National Telephone Co., Ltd.,  
Glasgow.

Gentlemen,—Your favour of the 11th is duly to hand, but as your Mr. Alexander Smith had already declined my offer to save you from the undignified position you have now placed yourselves in, not to speak of the position occupied by some of your employés, into whose conduct the criminal authorities are making investigation, it is for your London Office to adopt another mode of procedure.

The instruments will be produced at the proper time and place for inspection by competent authorities.

Don't you think some apology is due to Mr. Richmond for your employés' proceedings?

Yours truly,

A. E. MUIRHEAD.

#### Note on Localisation of Faults in Electric Light Circuits.

The ELECTRICAL REVIEW of October 10th, 1890, describes M. Henri Wilbrant's test for localising an *earth* fault when this occurs in one of a pair of buried leads of equal length and resistance.

Fig. 1 shows M. Wilbrant's method:—Accumulator with one pole earthed joined up through ammeters to looped leads A and B.  $C^1$  and  $C^2$  are deflections on respective ammeters.  $L$  = total length, or total resistance of loop, and  $x$  = distance of fault from test station.

Then  $C^1 : C^2 :: x : L - x$  and  $x = \frac{C^1 L}{C^1 + C^2}$  ohms or

metres, according as  $L$  is in terms of ohms or metres.

The above test, in its electrical development, is an adaptation of May's formula for localising an *earth* fault by the polarisation current emanating from the fault itself.

\* This had reference to a Lacombe cell.

May's test is as in fig. 2, which shows line (L) with fault at F, and earthed at both ends through similar galvanometers,\* the respective deflections of which may be termed  $C^1$  and  $C^2$ . The polarisation currents from

FIG. 1.

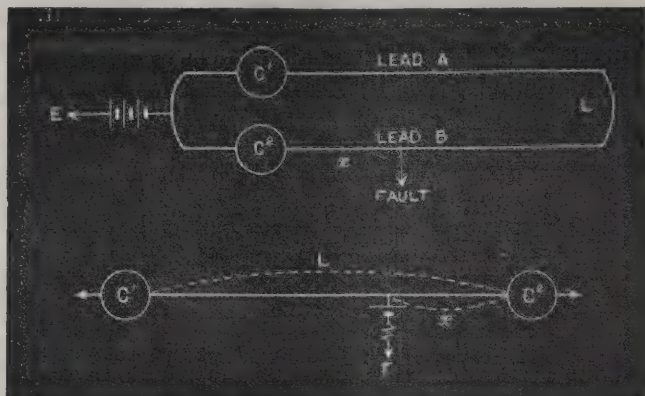

FIG. 2.

F, which flow through the two available branches, are, of course, inversely proportional to the resistances of those branches, so we have  $C^1 : C^2 :: x : L - x$ , and

$$x = \frac{C^1 L}{C^1 + C^2}, \text{ as above.}$$

The following modification of this test, by the writer, is also applicable to M. Wilbrant's method with accumulators and ammeters.

If—in May's test—F be electrically midway between the two galvanometers,  $C^1$  will equal  $C^2$ ; but if, not, then, of course, the galvanometer nearest the fault will give the higher deflection. Then, if the operator whose galvanometer gives the higher deflection, introduce a resistance R, sufficient to bring F electrically midway between the two galvanometers, sufficient—in other words—to make  $C^1 = C^2$  (see fig. 3),

FIG. 3.

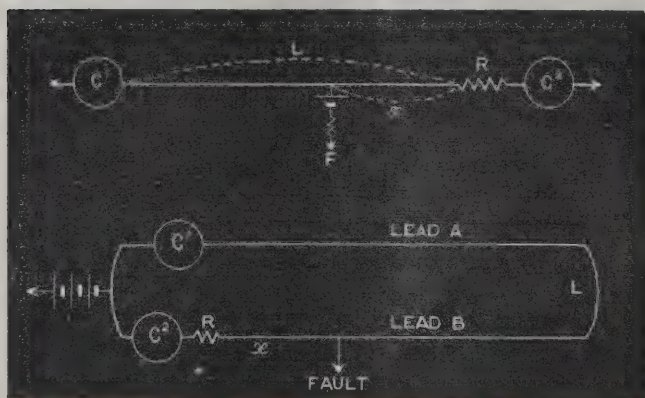

FIG. 4.

we shall have  $C^1 : C^2 :: x + R : L - x$ ;

or,  $C^1 (L - x) = C^2 (R + x)$

and  $x = \frac{C^1 L - C^2 R}{C^1 + C^2}$

but  $C^1 = C^2$ , so  $x = \frac{L - R}{2}$ .

applying the same modification to M. Wilbrant's test, we have (see fig 4) :—

$$C^1 : C^2 :: x + R : L - x, x = \frac{C^1 L - C^2 R}{C^1 + C^2}$$

and if  $C^1 = C^2$ ,  $x = \frac{L - R}{2}$ .

Perhaps this will be found the neater method of the

two, especially if the coils at R (\*) be arranged in resistance units equivalent to metres of line. Then, if  $L$  = total length in metres,

$$\text{Distance of fault} = \frac{L - R}{2} \text{ metres.}$$

Edward Raymond Barker.

B. S. T. Co., Madeira, Nov., 1890.

### The Life of Glow Lamps.

In your Correspondence columns of last week I notice a letter from Mr. Lott on "The Life of Glow Lamps on the Series System."

Before being able to attach any practical value to Mr. Lott's statement, might I ask him to kindly furnish the absolutely necessary figures or approximations as to the watts per C.P. that this lamp required initially and after burning 10,000 hours?

As I have often remarked before, in your columns, such statements of hours burnt, &c., are quite valueless unless C.P. and watt readings are simultaneously given. I believe it quite practicable for either a series or multiple glow lamp to burn considerably over 10,000 hours if always kept at a low enough efficiency, say 5 watts per C.P. and below.

If the particular lamp mentioned by Mr. Lott began at, say, 3 watts per C.P. and after 10,000 hours even went up to 4 watts per C.P., then I should consider that this denoted an excellent result and for practical reasons only would diminish the weight of Mr. Mordey's remarks, although his remarks must remain true in a theoretical sense.

C. J. Robertson,

Middleburg, Holland, November 12th, 1890.

The letter of Mr. Lott, in your issue of the 14th inst., is of interest. But at what efficiency was the particular lamp run? It may have rather a thick carbon which would account for the long life. But the "average life," is more important, with which perhaps your correspondent would favour us, and at the same time any information with regard to the reliability of the cut-out in the lamp would no doubt be of interest to your readers as well as myself.

J. E. Pearce.

November 17th, 1890.

### Telopy or Telephony.

It may appear as though we were looking ahead too much when we discuss the name of that which is at present non-existent. But, as we are told that we should first work out our ideal, and afterwards approach that ideal as nearly as hard circumstances will permit, we may as well act on the same plan in this matter of naming an undiscovered instrument. Now, as words are only symbols to express our thoughts to others by writing or speaking, it is necessary that words, when written or spoken, should express those thoughts as clearly, as shortly, and as euphoniously as possible. The series of words Telopy, a Telopist, the Telope, I Telepe, seem to fulfil the required conditions better than Telephony, a Telephanist, the Telephone, I Telephone. If that which is expressed by these words becomes as common as telegraphy, we shall probably have some totally different word used; just as we have—a wire, and I wire. Meantime, for writing and lecturing purposes, which of the above groups of words shall we employ to express seeing at a distance?

A. C.

November 18th, 1890.

\* If dissimilar galvanometers be used, knowledge of their respective figures of merit would still permit of comparison of deflections.

\* These would be similar in general construction to those used in electric lighting, and in such like heavy work.

THE ELECTRO-DEPOSITION OF COPPER.

WE call the attention of our readers to the letter from Mr. W. Stepney Rawson, which appears in our correspondence columns.

Mr. Rawson says the eight points in his letter published in our issue of November 7th "remain unanswered," and so he favours us with them all over again. To this we have to say that points 1, 2, and 3 consisted of the respective phrases "practically ridiculous," "equally ridiculous," and "like absurdity." These points were not "answered," though they were not neglected to be noticed. Points 4, 5, 6, 7 and 8 were all dealt with in their order. When Mr. Rawson gives us something other than absurdities and unsupported denunciations we can deal with it, and in his letter which we publish to-day Mr. Rawson does give us something tangible on the first point, which also bears on the second and third. In the calculations which we published on October 17th we allowed for a week of 60 hours, which is a very general basis to take for a week's work. Whether working a larger number of hours is a more economical plan depends largely on the relative importance of labour and plant. There is nothing incorrect about the figures we gave. Contrary to the Elmore plan, we stated clearly and definitely the basis of our calculations, and expressly emphasised their hypothetical character by following them with other data derived from actual work. Mr. Rawson says we should have taken 156 hours. Experience in other cases supports his contention for a larger number of hours per week, and when we make further calculations we will adopt a larger number. If Mr. Rawson will also favour us with his views of the number of tanks which should be taken into consideration, and we find that equally reasonable, we will adopt it, too, together with the further modifications which would then be necessary to arrive at a correct result. He knows well enough, however, that

we were not labouring under the impression that Elmore uses one tank only.

In the calculation referred to we arrived at a figure of 287,620 ampères. Mr. Rawson says these figures are absurd, and should be corrected to 3,000 ampères. Now if these two sets of figures are intended to represent the same thing, it is only necessary to place them in juxtaposition to show there is an absurdity somewhere. What our figures mean, and how they are arrived at, are clearly set forth in every detail. If Mr. Rawson will tell us what his figures mean, and how they are arrived at in similar detail, the absurdity may become apparent. Without attempting to prophesy we think we may say that the probability is the absurdity will be found not in either of the figures but in their comparison. We may here quote for Mr. Rawson's benefit a paragraph in the same article :—"Placing a number of depositing tanks in series would not make matters any better, for what is gained in one respect is lost in another."

These remarks cover Mr. Rawson's first, second, and third points. The fourth point contains a new claim to economy in the Elmore process by the reduced size of tanks necessary. We have no wish whatever to minimise this, or any other, advantage, and if Mr. Rawson will also favour us with particulars of the extent of this economy, we shall be much obliged to him. We have nothing to add to our remarks on horse-power, which is the fifth point. On the sixth point, we have only to say, in addition to what we have said already, that the age of our £12 data is immaterial. Moreover, the Norddeutsche Affinerie, of Hamburg, whose figures, it will be remembered, were the lowest of those quoted on p. 479, and to whom we applied for verification, sends us the following ominous reply :—"We beg to say that the figures in question are incorrect, but we are not willing to rectify them." Reductions, if any, apply generally, and whether £12 or £8 be correct, the Elmore Company will have to deal with the market price, and the market price will be dependent upon competition. The simple

questions are : (a) Can electro-deposited copper compete with copper otherwise prepared, for use under circumstances in which electro-deposition is an unnecessary refinement, or (b) in cases where electro-refining or depositing is advantageous, are the economies of the Elmore process such as will enable the company to undersell everybody else in the market, and still pay a dividend on the purchase price of the patents? The further question of the protection afforded by the said patents is, of course, very material, though in a different category. On the seventh point, we must ask Mr. Rawson not to make too much of our disclaiming any intention to reflect upon the quality of the articles produced. We did so simply in accordance with our usual custom not to express an opinion without due consideration. It will be time enough to commend or condemn the quality of the articles when they are in the market. The eighth point brings us to the report of Mons. Secretan, with which we consider it necessary to deal somewhat fully. Before we do so, we may remind Mr. Rawson that we have been through his points, number by number. If there is still something we have left unsaid, he will doubtless remind us of it. In such an event, may we suggest to him that in controversial discussions there is some danger of losing sight of the main point by enlarging on side issues. We have no intention of permitting this to be done if we can avoid it. Therefore, perhaps Mr. Rawson, in any future communication, will bear in mind that the questions of real importance are those we have asked in reference to point six.

The report of Mons. Secretan, as presented to his directors, contained a statement of the cost of production, and the prices to be realised. This would have helped materially to the elucidation of the questions we have propounded, but unfortunately it is represented in our copy by an asterisk and a footnote. But sufficient remains to enable us to form an idea of its value.

Mons. Secretan, accompanied by two gentlemen holding official positions, and others who are described as very able technical men, but are unnamed, went to the factory at Leeds to inspect it, and to make themselves acquainted with the Elmore process and its cost. Some figures were given them (they have not been sent to us), and they were able to satisfy themselves that those figures were perfectly exact.

The statement represented by the asterisk is prepared on the supposition of an output of 900 tons per month—which could be reached in a very short time. The expenses are taken at a maximum—nothing on earth can make them heavier, whilst it is only necessary to prepare a definite project and they are at once reducible. The statement was not so thorough as it might have been, since some articles sold at high prices but cheaply made are omitted from it, and have to be specially mentioned in the report. No hint is given as to the nature of these articles. They may be *articles de vertu*, or they may be *articles de cuisine*. In his pre-Elmore days Mons. Secretan was famous both for his art collection and his hospitality, so both may have been

in his mind. Mons. Secretan has rapidly acquired the true Elmore manner for, having made a series of statements, they become “well established,” and work must be commenced forthwith. The statement having been prepared on a basis of 900 tons, Mons. Secretan concludes that the directors may find it more prudent to arrange for an output of 300 tons. We are tempted to ask whether a profit does not, to some extent depend upon the extent of output, and whether the brilliant result doubtless foreshadowed in the statement is equally applicable to an output of exactly one third? The report concludes with the remark that manufacture being once decided upon, one can, without rashness, predict a brilliant future for the company, and instances itself (the report) in another characteristic Elmore touch as a justification of the heading of the prospectus “a revolution,” &c.

This is the report which Mr. Stepney Rawson sends us in confirmation of his statement that competent authorities have verified the correctness of the statements made as to the cost and quality of the articles manufactured. This is the report to act upon which the Directors pledged the whole substance of the company for a loan of £50,000.

Had Mr. Rawson permitted the statements to have remained without this confirmation, the statements would have been more generally credited. Had the directors not acted upon the recommendations of such a document they would have had so much the less to answer for.

So long as the Elmore Company have an undoubted right to withhold information, and exercise it, they must expect people to form impressions upon the material open to them. In businesses conducted in a business-like way, enquiries as to cost of manufacture are seldom indulged in and less seldom conceded. The Elmore business is not conducted in such a manner. From first to last the proceedings have been such as to give but one impression, which we will express in plain English as absolute distrust.

We are concerned for the possible waste of money, as we have said before. The borrowed £50,000 and the balance remaining to the company after payment of the purchase money, are not yet spent. Are there none of the directors who can see the wisdom of waiting until the English factory pays its way before starting a French one? Is there not one shareholder sensible enough to realise that loss of time is better than loss of money, and protest accordingly?

The directors should remember that they will not always have an undoubted right to withhold information from everybody. A time will come when they will have to render an account of their stewardship. When the time does come, if the account be unsatisfactory, stock phrases at the shareholders' meetings will not avail them much. They cannot say that the possibilities of adverse results have not been put fully and fairly before them.

Notwithstanding the risk we run of having some indignant shareholder complain of the number of our columns devoted to the subject, there are two other phases of the Elmore question which we should like

to touch upon. Mr. William Elmore has written to the newspapers to explain that the fall in the price of the shares is due to the recent financial crisis, and the realisations of weak holders. Mr. Elmore will find a more reasonable explanation in our columns. On October 3rd, we wrote that the public should clearly understand that the price of Elmore shares is simply a measure of the reliance of the holders on the absorption of more sub-companies. The same remarks apply now. The change in price is the change in the reliance of the holders.

The other phase is the "Trust." Now a trust may be formed for one of two reasons—or a combination of both: to obtain more cash from the public, or to concentrate voting power in the inner circle. The only one of these which concerns us is the first, and we think there is now little risk of its being operative. The public can understand that inasmuch as two blacks do not make a white, neither do four insecurities constitute a security.

---

## UNDERGROUND SUBWAYS.

---

SOME time ago a Bill was promoted in Parliament to authorise the construction in London of a subway in which all underground pipes, and particularly gas and water mains and electric light cables, should be laid. The Bill, which was not formulated in a judicious manner, was strongly opposed by the gas, water, and electric light companies, and was ultimately thrown out. This result has, however, not discouraged the metropolitan local authorities. The members of the Strand Board of Works are uniting with those of other districts in drawing up a memorial to be presented to the London County Council, asking that a Bill should be introduced in the next session of Parliament to authorise the construction of a subway to contain all underground pipes, and thus prevent the present method of indiscriminate laying adopted by the various companies.

That the time will eventually arrive when some kind of subway, or subways, will be necessary in the metropolis for the accommodation of the various pipes and conduits there can be little doubt, but at present, and probably for some time to come, there does not appear to be any such necessity. If, indeed, the same conditions prevailed here as now obtain in New York, the companies concerned would possibly appreciate an efficient subway or subways, provided, of course, they were not required to contribute towards the cost which, to say the least, would be enormous. The *Engineering News*, of New York, gives in its issue of the 1st inst., a page plan of the pipes, conduits, &c., at the intersection of Broadway and Fulton Streets, New York City, prepared from a survey and drawing made by order of the Commissioner of Public Works. The plan shows what is termed the "Broadway Underground Tangle," or, in other words, a labyrinth of gas and water mains, sewers, Edison conduits, electric subways, electric subway vaults, electric subway air pipes, Com-

mercial Cable Company's conduit and vault, pneumatic tube boxes, Steam Company's conduits, steam expansion joint vaults, return pipes, cellar vaults, together with manholes, gas and water stop-cocks, receiving basins, &c. This medley of pipes and conduits is being aggravated by the continual undergrounding of electric light cables, which were formerly carried overhead in the American "happy-go-lucky" fashion. This system of indiscriminately placing below ground all kinds of pipes has, indeed, not been without effect. Explosions, due to various causes, have been the order of the day, and even now frequently occur, although very little is heard of them—possibly because "use is second nature." These explosions are due to a variety of causes. The escape of steam from the steam pipes has deteriorated—and continues to deteriorate—the insulation of the electric light mains leading to the formation of short circuits, and the escape of gas from the gas mains has then come to the fore, with the inevitable result of a nice little blow up. The dropping of lighted matches down manholes has also contributed its share towards destruction, whilst sewer gas has likewise given its assistance.

Surveys are at present being made of underground Broadway, and the cross sections already taken show gas and water mains, the latter up to 36 inches in diameter, crossing and recrossing the street without any apparent cause, in the case of the gas mains, whilst electric subways and conduits, pneumatic tubes and steam heating pipes interlace with each other, and twist about sewer manholes and over cross town sewers in an utterly lawless and incomprehensible manner. This deplorable state of affairs, in this and other streets in New York City, will, however, probably be changed, and some kind of subways will be built to enclose the various systems of pipes.

Fortunately, with the exception of the Strand, along which probably more traffic is carried daily than on any other thoroughfare in the world, London streets are tolerably free from a confusion of underground pipes. Nevertheless, considerable difficulties have arisen in many other streets, owing to the lack of sufficient space to lay electric light conduits either at a sufficient depth, or in the most convenient spot desired by the companies. The proposed Bill would, if it passed through both Houses, provide for the construction of a subway which would contain all the systems of pipes and conduits—an ideal of perfection, according to the promoters. There are, however, many difficulties in the way of bringing such a scheme to a successful issue. In the first place, the cost of making the subway would entail an enormous expense—probably several millions sterling—and who would pay the piper? The money would hardly be raised on loan by the London County Council, for, if so, the companies interested would, on the completion of the work, be called upon to pay a rental for utilising the subway, and this would amount to a not inconsiderable item in the cost of production, which, correctly defined, is that sum which remains after *all expenses* have been deducted. Provided that the County Council did not raise the money, an attempt might be made to get a clause inserted in the

Bill to compel the gas, water, and electric light companies themselves to construct the subway, since it would be built for their convenience—oh, no—for their use. That such a clause could be passed seems incredible. The companies are already strongly represented in Parliament indirectly, and, with the assistance of other members, it is fair to assume that such an objectionable clause would be rejected.

The proposed subway would during the course of construction not only cause considerable interruption in the supply of water, gas and electric light, thus entailing great loss to the companies, but it would also necessitate the reorganisation of the three systems of distribution, another item of great expense. Again, if a subway is to be made, the question arises as to the kind of subway to be constructed, but this need not be referred to in detail. Suffice it to say, that if a subway is to be built, the gas, water and electric light mains must not be placed therein after the haphazard style adopted in Paris or in New York. The ideal subway appears to be one arranged in divisions, each being distinct from one another, and each being water and air tight. As to the raising of the money, this matter had better be left for the consideration of those long-headed individuals who have plenty of spare time, and scarcely anything to do but inconvenience public companies and spend ratepayers' money.

"Necessity is the mother of invention," and when the time arrives for the construction of a subway, necessity will show itself in the elaboration of a suitable subway. At present, however, there is no such need, and the proposed Bill, if it assumes definite form, will doubtless meet the fate of its predecessor.

regard to the coil. To prove the principle on which incandescent lamps are operated by an induced current, a glass jar of water was placed over the coil; submerged in the water was a coil, to which was attached an incandescent lamp, which burned brilliantly. By simply raising the jar the intensity of the light produced was regulated in a most perfect manner, the lecturer saying there was no longer any truth in the assertion that the electric light could not be raised or lowered. A jar of water being held over the coil, into which was dropped a hollow copper ball, the ball commenced to rotate. Professor Thomson also showed some experiments in electric welding, and a device somewhat similar to a gyroscopic top. The final experiment was extremely interesting. A small motor, consisting of a circular coil, being fixed horizontally with a slot cut through one side, a pivotted disc working in or close to the slot rotated rapidly when the current was turned on. Removing the disc the machine became a counterfeit coin detector, for it possessed this remarkable characteristic that if a genuine silver coin was placed near the slot it would be drawn into the vortex, as it were, and instantly flung out on top of the coil while a counterfeit coin would not be in the least affected.

The American Eagle  
on the Wing,

The *Boston Herald*, of November 5th, contains what is apparently the reproduction of an article written in the *New York Sun* under the somewhat alarming title of "A Source of Danger." Fearful as to what fresh perils awaited unfortunate humanity, we read, and trembled. Imagine then our relief when we found that it was only our old friend electric lighting again to the fore, or let us say, at sea, for the sub-title of the article in question is "Improper Electric Wiring of Ocean Steamers on the English Plan." We are told that the *Etruria*, on a recent passage across the Atlantic, was on two occasions threatened with fire, owing to the imperfect insulation of the electric light wires, and we alluded to this matter in a Note (p. 368), as also did Mr. Rankin Kennedy in our correspondence columns (see REVIEW for October 3rd), in a letter which might be again read with advantage. Horror struck at the thought of the frightful catastrophe which might have attended the fires which nearly occurred, we read on, hoping to find some brilliant suggestion for the prevention of this source of danger. And we found it—an advertisement of Edison plant. But let us give the article full justice. The case of the *Etruria* serves as a *raison d'être* for instituting a comparison between the American and English methods of ship-wiring. Needless to remark, it is not our cousins who suffer in the contrast. We are informed that ship installations on the English plan have not sufficient safety fuses, that the insulation of the wires is imperfect, and that the employment of the hull as a return circuit is not only an inefficient, but absolutely dangerous plan. It will be of interest to English electric lighting engineers to learn that the two-wire, or metallic circuit, is the "American" method. Nor is it of any less advantage to realise that this is the particular system in which the copper wires are carefully insulated with "a material," then drawn through lead pipes, and finally let into a heavy moulding. Let English engineers take heed to this note of warning. It is only a matter of time until the "criminally dangerous system" adopted by them in ship wiring must give way to the "vastly superior" American method; at least, so says the *Sun*.

The Properties of  
Alternating Currents.

THE Boston Electric Club held its first meeting of the season on the 10th inst. Professor Elihu Thomson delivered the inaugural address, choosing for his subject "The Properties of Alternating Currents," and illustrating his lecture with numerous experiments. The Professor said that the alternating current had been experimented on with alternations as high as 8,000 per second. What was really needed was a machine to produce 500 trillions of vibrations per second, from which some wonderful results might be expected. He then described the general properties connected with the alternating current, and to demonstrate his statements he had a powerful coil placed on end on a stand, and secured to a wooden upright, to which he attached first one device and then another, as he required. The coil was excited by an alternating current, a copper ring, about six inches in diameter and three-eighths thick, was held in the air above the top of the coil, and by induction the ring was held in mid air. Another ring then placed below the first, clung to it by magnetic force. The rings either floated or jumped about according to the angle the rings made with the coil. A copper hollow ball, placed on a plate just above the coil, began to rotate, but was speedily stopped by introducing a sheet of copper between the plate and the head of the energised coil. A pivotted copper disc revolved rapidly when brought near the coil, its direction in running depending on its position in

## Subway Explosions.

THE repeated and alarming explosions which have occurred in the street junction boxes of the Newcastle Electric Supply Company, which, besides causing considerable derangement of the flagging, have occasioned slight injury to several persons, have been attributed to leakage of gas; but as the explosions have taken place during or after rain, and the boxes are by no means wet proof, it is at least open to doubt whether the true explanation is not the formation of hydrogen owing to the 2,000 volt alternating current leaking between the bare uninsulated connectors that are employed for joining the mains, through water in the boxes, which hydrogen, being mixed with air previously in the box, is fired by a spark, resulting on the level of the water becoming depressed, and the contact being thereby broken. In any case, that explosions can be originated in this manner is capable of experimental proof. It is only fair to the other electric lighting company in Newcastle—the Newcastle and District Electric Lighting Company—who have now an equivalent of 7,000 10-C.P. lamps coupled to their mains, to mention that no accident of this kind has occurred in connection with their service since starting in January last. This company's junction boxes being of cast iron, with screw-down lids, are quite water-tight, and the joints in the cables being all insulated with India-rubber vulcanised *in situ*, it is difficult to imagine how in their case any explosion could by any possibility take place.

## The Electric Light on Ship-Board.

THE Institute of London Underwriters, stimulated by the appeal of Mr. Leonard Wakefield, of Lloyd's, is endeavouring to have the system of electric lighting at sea set at once upon a more satisfactory footing. Lloyd's Register of British and Foreign Shipping, better known as "The Book Committee," were requested to indicate in their Register every instance in which a vessel is lighted by electricity, and to bring electrical installations under their rules of survey, and the engineer surveyors of the Book have drawn up and submitted a practical report, concluding with a scheme of regulations for adoption by the committee. The dangers involved by the use of the electric light on board ship are, says the report, of two kinds. First, the dynamos themselves, and the electric currents in the cables, have an influence on the ship's compasses; and, next, there is the more obvious danger of fire. In order to minimise the first risk, it is recommended that dynamos and electric motors be placed as far as possible from the compasses. Where the single-wire system is used, and the ship itself is made a medium for the return current, the compass is in danger of being deflected. By resorting to the double-wire system, the return current can be so carried past the compass in the reverse direction as to counteract the influence of the main wire. This system, therefore, is encouraged by the engineers. Where, however, the single-wire plan is, notwithstanding, followed, then the committee are advised that the distance between the wire and the compass should in no case be less than 15 feet. It is recommended that special precaution be taken to test the compasses whilst the dynamos are working at their full capacity, and the same tests be applied whilst the groups of lights are switched in and out. With respect to the fire risks, they are more mul-

tiferous. Great care should be taken to secure a perfect insulation of the wires, not merely of a high initial resistance, but one which will be permanent. The conditions of non-conductivity on shore and at sea are different things. An insulation, which may be permanent enough on dry land, may fail to hold out against conditions maritime—against the changes of temperature, the moisture of the salt water incidental to transit at sea. The recommendations of the report as regards the effective insulation of wires and cables are of great value, and the electricians have further called attention to the fact that methods of protection which may be good enough in some parts of the ship may require supplementing in parts where the risks arising from rough usage or heat are more considerable. Special advice is given as to the safeguarding of joints and junctions against the effects of moisture. To safety fuses, also, close attention is recommended. But the "cut-out" is no protection against the consequences of thinning of the wire by corrosion, or against a break caused, for example, by a too taut setting of the wire. These dangers can only be prevented by careful attention to the work throughout. In petroleum vessels, a special danger has to be provided against; for, an incident of the carriage of petroleum is the accumulation in certain localities of an inflammable vapour, which, it is believed, is liable to be ignited by the electric spark. On vessels which had been recently discharged of their petroleum, heavy accumulations of explosive vapour are especially to be feared. The switches on oil-carrying vessels should, it is urged, always be placed above the upper deck, in the open air, or in places removed from possible gaseous accumulations; and other suggestions are made by the electricians to similar purport.

## The Telephone in Competition.

FOR the past eleven years a highly successful telephone exchange, conducted by a local company, has been in existence in Sheffield, and during the latter portion of that time the National Telephone Company has also had an exchange in the same town. As the expiration of telephone patents approaches, the competition between these companies grows more keen, and the rates that are now being charged in Sheffield may, in all probability, be taken as an indication of the rates that will obtain in all other large towns, in the immediate future. The local company recently announced a reduction of rates to £7 per annum, and this was at once followed by a reduction on the part of the National Company to £5 per annum. In view of the arrangements that are rapidly being made to challenge the monopoly of the National Telephone Company in all large centres, by properly constituted companies, it remains to be seen how soon the National Company will still further realise the nature of the coming struggle, and how soon it will meet the same by a general reduction of rates to the level to which it has shown the way in Sheffield. Meanwhile the Sheffield Company is preparing to join hands with the new companies for mutual support, and if inter-town communication is to be a real necessity of future telephonic developments, it may reasonably be anticipated that through wires for the same will readily be provided by the Postmaster-General, and probably on terms that will be less burdensome than those that have been self-imposed by the National Telephone Company.

## ON THE ACTION OF LIGHTNING DURING THE THUNDERSTORMS OF JUNE 6th AND 7th, 1889, AT CRANLEIGH, SURREY.\*

By CAPT. J. P. MACLEAR, R.N., F.R.Met.Soc., F.R.G.S.

DURING the thunderstorms of June 6th and 7th, 1889, so many trees were struck within a radius of 4 miles from Cranleigh, that I set to work to discover, if possible, the cause of selection of these particular trees; for, contrary to general expectation, they were not the highest nor the most prominent in their immediate vicinity; and though I cannot say I have solved the question, as the causes of preference appear to be very slight, yet I think I can put forward some interesting facts which may help us to a further knowledge of the nature of the electric discharge, and the course it may be likely to follow.

On June 6th, the storm first appeared to the southward of Cranleigh, about 4.43 p.m., and it passed about 4 miles to the south-west. About 5.30 p.m., shortly before rain commenced, the following objects were struck, apparently about the same time, but as no accurate observations were made as to time, it cannot be determined whether one or several discharges were concerned. On Dunsfold Common, 4 miles south-west of Cranleigh, a cottage was struck, a chimney at the south-east end knocked down, and the register grates on two floors started from their places; a haystack about 100 yards south of the cottage was set on fire, and two poplars 300 yards west of the cottage were struck, each tree having a score down it,  $1\frac{1}{2}$  inches width of bark being stripped off. On Hascombe Hill,  $1\frac{1}{2}$  miles north of the cottage, and 400 feet above its level, a spruce fir was shivered; at Alford,  $1\frac{3}{4}$  miles south-east of the cottage, two oaks were struck, one was only scored, but the other was split (this latter tree was struck again and splintered the next day); also three oaks about a mile to the westward of the cottage were struck, but as it is only conjecture that they were struck at the same time, I shall not refer to them again. More trees may have been struck in the neighbourhood, but not noticed.

As for the causes of these objects being selected, it will be seen that they lie nearly in a line north-west and south-east, 3 miles in length. Mr. Marriott has shown (*Quarterly Journal*, No. XV., p. 222) that the storm was passing in a north-west direction with a south-east wind; it is possible that the storm was delayed by the high Hascombe hills, and the charged cloud thereby concentrated. The spruce fir was very prominent on the southern brow of the hill; it divided into two arms nearly in line with the stem; one arm was thrown to the ground, the other blown down by the wind a few hours afterwards. At the junction of the arms there was a great deal of turpentine, which was thoroughly blackened. In this case I should consider that the prominence of the tree made it the best communication to earth, and that the collection of turpentine at the juncture of the arms was raised to explosive temperature, and split the tree.

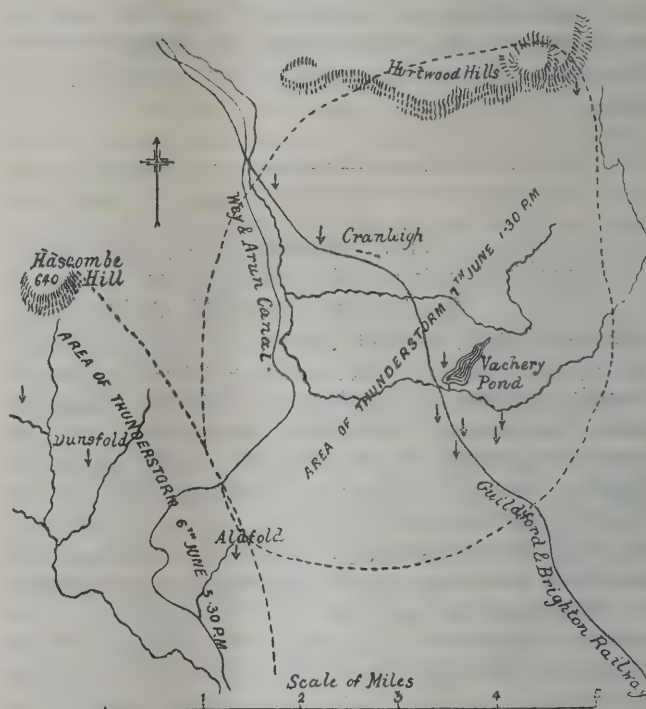

The cottage, haystack and two poplars on Dunsfold Common do not immediately suggest a cause of selection, but from their position the ground falls to the south-east in a wooded valley through which the Arun and Wey canal runs, and on the other side of this wooded valley are the Alford trees. Streams into the canal run from near all the objects struck, and though I hesitate to advance this point, it is possible that the earth electricity was thus able to collect more readily at these places than at others under the cloud. It would be exceedingly interesting to know if these objects were all struck by the same discharge.

On June 7th, the storm began with little warning at 1.10 p.m., and was at its height at 1.27, when there fell the heaviest rain known to the oldest inhabitant. About 1.30 p.m. the following objects were struck:—Near Vachery pond, a large reservoir for the Arun and

Wey canal,  $1\frac{1}{4}$  mile south-east of Cranleigh, six oaks a chestnut, and an ash, in various positions within  $\frac{1}{2}$  mile of the pond and about  $\frac{1}{4}$  of a mile apart, a young fir and three young oaks in the middle of a copse on the slope of the ground near the pond, four oaks  $\frac{1}{2}$  a mile south of Cranleigh, one oak on Cranleigh Common, a chimney and stable 1 mile north-west of Cranleigh, besides the oak tree before mentioned at Alford, and a single oak occupying a fairly prominent position on the slope of the high hills  $2\frac{1}{2}$  miles to the north-east of Cranleigh. This last tree was struck just before the rain commenced on the hill, and was split; the other trees struck, during the rain, were only scored.

Here the area of discharge extends along a line about three miles in length north-west and south-east, as on the previous day; and with the exception of the Alford tree before referred to 3 miles to the south-west, and the tree on the hill 3 miles north-east, all the objects struck were scattered along the line of railway, and at no great distance from it.

It is not easy to see the cause of selection, for these trees were not the most prominent nor were they on the highest ground in the vicinity; the only feature the groups possessed in common being that they were all either near ditches which were full of running water, or else near temporary courses taken by the deluge of water from the higher to the lower ground. The most puzzling case is that of the young fir tree and three young oaks in the middle of the copse near

Vachery pond; they were not higher than the other trees in the copse, but there certainly was a temporary water course running close to them; other trees, however, stood equally close to the water, and unless a large squirrel's nest of moss on the top of the young fir be called upon to account for the selection, it still remains obscure. Another curious case is that of the stable struck, which was overshadowed by tall elms, where it might have been supposed that these would have taken the stroke.

Of the species of trees struck, the oak is the most frequent, and I am inclined to believe that the reason is not that there are more oaks than other trees in the neighbourhood, but that the roughness of the bark causes gaps of its continuity as a conductor; elms, firs, poplars and chestnuts have been struck, but it is said that the beech is never struck.\* It has been said, also, that oaks are more frequently struck in the spring and other trees in the autumn, but this requires confirmation.

\* Read before the Royal Meteorological Society.

\* "The Action of Lightning." By Colonel Parnell.

The injuries to the trees are of two kinds: the first, by far the most common, is simply a score out of the bark up the trunk of the tree, out along one limb, and then by perhaps two or three branches to the outer twigs; in some cases portions of the bark are blown off as well. A very good illustration of this effect is found in a paper by the Rev. O. P. Cambridge, "On the Effect of a Flash of Lightning at Bloxworth," April 9th, 1886.\* In these cases I imagine that the rain is falling, and one or more streams of water are running down the sides of the tree, forming a conductor which becomes insufficient, at the time of discharge, to carry off all the electricity, and therefore becomes so suddenly converted into steam as to blow out the bark along the line, and if there is communication with the sap by a knot, hole, or other flaw, the sap is also converted into steam and the bark blown off.

The other form is the shattering of the tree, which I imagine to occur when the electricity is insufficiently carried off by the outer surface, and collects at the junction of some main branch with either the stem or with some other branch, where there is perhaps a cavity of water in it, or a collection of moist dead leaves; the tree is then easily rent by the explosion of steam generated. If the tension be very great, and especially if the air round the tree be dry, the sap may be violently exploded, and trunk splintered and shattered as if by dynamite.

Of the trees which I have examined here, the only ones shattered were those struck before the rain fell; the others were scored simply, with bark blown off.

In the case of the stable struck on June 7th, I can only think that the electricity collecting at the top of the overhanging elm tree found a better conductor than the trunk in the hot moist air escaping from the near gable of the stable, and the hot air expanding blew the corner tile off to find a better vent. As to the cottage on Dunsfold Common, struck on June 6th, I can trace no cause for selection; the appearance of the chimneys suggests an explosion of air.

As the result of my examinations I can only say that the causes of selection of objects struck appear too slight to be readily perceptible, or to enable one to say beforehand that such and such an object will probably be struck. It seems that during rain every tree is conducting electricity, and a disruptive discharge takes place where the conductor becomes insufficient. This would depend on the position of the cloud, the amount of foliage on the tree, its condition of moisture, and its connection with running water. Also I may point out, as shown by Prof. O. J. Lodge, that if an upper cloud should discharge to a lower one, the lower one may then discharge to earth violently without regard to any conductors.

It would be desirable if those who have the opportunity of observing objects immediately after they are struck would note the surrounding conditions and proximity to water, and whether, in the case of trees struck during rain, the score is on the side on which the rain beats.

### THE HAZELTINE ARC LAMP CARBON SHIELD.

MANY of our readers readily recall the time when arc light carbons were sold at the rate of \$1 a dozen and were not even then considered excessive in price. Since those pioneer days, says the New York *Electrical Engineer*, there has been a continual diminution in the price of carbons, but with the enormous increase in the number of arc lamps burning nightly, the total expenditure involved amounts to many hundreds of thousands of dollars annually. It has, therefore, been the aim of many to increase as much as possible the life of the carbon on the one hand, or to increase its illuminating power with the same expenditure of electrical energy. These attempts have resulted in the

application of various devices, either mechanical or as ingredients of the carbon itself, but, so far as we are aware, scarcely one of these methods has come into practical use, the pure carbon of to-day being still universally employed. The advent of a simple device by which an actual economy in the operation of the arc lamp is effected will, therefore, be of considerable interest, and for that reason we desire to call the attention of our readers to a simple and effective device of the kind due to Mr. W. B. Hazeltine, Jun., of the Hazeltine Electric Company, of St. Louis. This device, which is illustrated in the accompanying engravings, figs. 1 and 2, consists simply of a sleeve of refractory material, forming a protective shield, or tip, which is freely suspended so as to hang in close proximity to the tip and the upper carbon close to the arc, the suspension device being so arranged that the sleeve is automatically maintained at its proper position near the arc. The effect of this simple arrangement, as has been shown by actual experience, is that the life of the carbon is practically doubled, so that an ordinary eight-hour carbon is able to burn 16 hours without retrimming. The exact action to which the saving in carbon and increase in

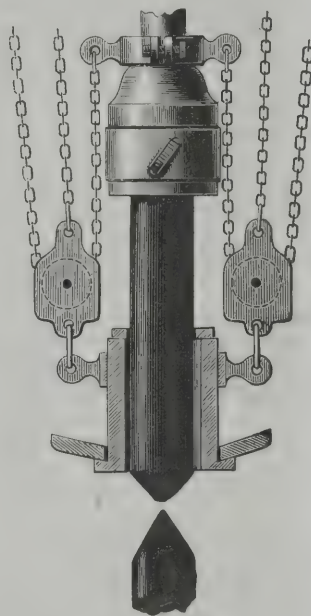

FIG. 1.

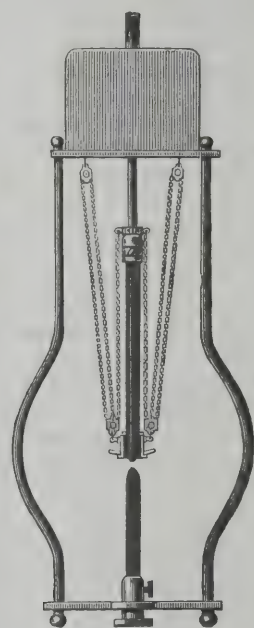

FIG. 2.

life is due has not yet been fully analysed, the fact remaining, however, as described. The shape of the carbon when protected by the shield is modified somewhat from that usually noted. The economical advantages gained by this device must be apparent. In the first place, not only may a large saving be effected in the carbon bills, but another important item, the cost of trimming lamps, may be reduced in almost the same ratio. A further attribute of the shield consists in the fact that it acts as an automatic cut-out whenever one or the other of the carbons is consumed, thereby preventing the destruction of the carbon holder, it being impossible, of course, for the holders to approach nearer to each other than the length of the shield. Aside from the economy in carbons and trimmer's services, it is pointed out that the convenience to customers of having their lamps trimmed every other day, instead of every day, as at present, will no doubt have the effect of increasing the popularity of the arc lamp. Besides, the consumption of the carbon is so complete that very little carbon dust settles at the bottom of the lamp, so that cleaning may also be deferred to the same time as trimming. We may add that the Hazeltine shield has been tested by Mr. James I. Ayer, superintendent of the Municipal Electric Light and Power Company, St. Louis, operating 3,000 lights, who, after a careful trial, fully corroborates the inventor's claims, which are also attested by the Western Electric Company, in whose factory a similar test was recently made under the supervision of Mr. C. A. Brown.

\* This paper is in the Library of the Royal Meteorological Society.

## THE LINEFF SYSTEM SCORES.

"HURRAH! at last the battle is over and we are victorious. The fighting was severe, but, thank God! we have won the day." These words, which were once uttered by an old English soldier, are peculiarly applicable to the position of the West Metropolitan Tramway Company in relation to the Hammersmith Vestry. It is the old, old story of the opposition of local authorities to electric lighting and traction, and when the local "powers that be" object in such cases, it requires a high *voltage* to induce the Board of Trade to overrule their objections. So much is this the case, that the latter Department almost invariably supports the Vestries, Local Boards, municipalities, &c., which constitute local authorities.

When in an 1887 Session of Parliament the West Metropolitan Tramway Company obtained a special Act authorising the employment of electric traction on the company's lines—about  $8\frac{1}{4}$  miles long—it was thought that electric street traction would assume a definite form in the metropolis. The tramway company and others interested were, however, doomed to disappointment. The local authorities, and particularly the Hammersmith Vestry, now locally notorious as having spent over £1,000 of the ratepayers' money in opposing the granting of the above-mentioned Act, flatly declined to give permission for the use of the Lineff open conduit system which the tramway company had originally intended to lay down. The latter were wise in their generation. The Act did not authorise them to break open the roadways, and as the local authorities were obstinate, the company did not care to experiment with the vagaries of storage battery cars. "Wise men of the west" were, indeed, the directors of the tramway company.

A year passed away, and in that quiet corner of the Chiswick dépôt of the tramway company experiments were commenced with a new system of electric traction. These were conducted for some time, until the Lineff closed conduit system became experimentally an accomplished fact. Before the first public demonstration of the system was given, the line was shown in operation to the local authorities.

It was then thought that, as the new system overcame the objections raised against the open conduit method, the local authorities would readily consent to its adoption on the Hammersmith-Kew line, or on that from Young's Corner to Uxbridge Road. Unfortunately, this expectation was not realised.

The Brentford and Chiswick Local Boards gave their permission, but the third local authority concerned—the Hammersmith Vestry—again refused to do so. The tramway company were thus placed in an awkward position. It was either necessary to again apply to Parliament to authorise the breaking up of the roads, or, Micawber-like, to wait "for something to turn up." Pressure—high pressure, of course—was, however, brought to bear upon the vestry, who a few weeks ago resolved to grant permission for the laying down of the magnetic conductor, subject to a favourable report being received from an expert whom they appointed. Favourable reports were received by the vestry from Mr. W. H. Preece, Mr. G. Kapp, and Prof. Robinson, and on the 20th inst. the vestry unanimously agreed to the proposal of the tramway company to work the line from the Uxbridge Road Station to Kew, a distance of three miles, by the Lineff closed conduit system. The work of laying down the magnetic conductor is to be commenced at once. Thus terminates one of the most obstinate battles which have taken place between local authorities and the promoters of electric traction.

It might appear from the foregoing that the blame has been entirely on the part of the Hammersmith Vestry; but it is believed, and has been stated, that the vestry was perfectly justified in opposing for so long the adoption of the Lineff system. Whatever the reasons for this may be, it is satisfactory to find that after a struggle extending over a period of nearly three years, a definite decision has been reached. It only

remains to be seen whether, when the system has been laid down, the anticipations of the promoters will be realised. We trust that this will be the case, as it will be the first underground closed conduit system to be shown on a practical working scale.

## COMMUNICATIONS FROM AUSTRIA-HUNGARY.

[FROM A CORRESPONDENT.]

THE Popp Compressed Air Company are making everywhere great efforts to obtain a footing for their system in Austria-Hungary. Last week M. Victor Popp made his appearance in person at Budapest in order to carry on a propaganda for his system in influential quarters and to take steps for obtaining the long-coveted concession for erecting and working a compressed-air central station at Budapest. Unless, however, the indications are untrustworthy, the efforts of the Popp Company will not prove successful at Budapest.

In Vienna the Lower Austrian Trades' Association was concerned last week with the Popp system. 249 Viennese firms, tradesmen and industrialists, have handed in to the council of management of the above association a memorial in which they urge that 1,400 Viennese industrialists have subscribed to the "International Compressed Air and Electric Company" for a total of 17,000 H.P., but that the application for a concession has been under consideration for more than 18 months in the Viennese Municipal Council, therefore the association is besought to take steps for the acceleration of their affairs. The council of management has introduced this memorial to the Municipal Council. The president of the association has personally handed the memorial to the presidency of the Municipal Council, and applied also to the director of the magistracy. From both sides the assurance has been given that now the great question of the union of the city of Vienna with the suburbs, no longer claims all the attention of the council, the affair will be quickly taken in hand and brought to a conclusion. But with what result the future must show.

On the 13th of this month the Vienna central station of the International Electrical Company was set in work with the secondary installations connected. The next day other points were experimentally connected, and as the trials on both evenings gave satisfactory results, the regular working will begin to-day, at first with a capacity of 2,000 H.P., with successive extensions up to 10,000 H.P.

Herewith the total cable net of the company which at present branches out for the length of about 33 kilometres and is laid down in various wards of the city will be set in action. The Imperial Palace will be among the objects illuminated.

At the central station of the Brush Company at Temesvar there occurred on the 14th inst., a very deplorable misfortune. About 5.30 p.m., just as the machines for lighting the streets (Brush continuous current dynamos) were set in action the main driving band got in irregular vibration. The attendant on the dynamos and the foreman rushed up with spreading rods to prevent the band from slipping when a whitesmith, who had been employed in the installation for about four weeks, a man of 24 years of age, named Franz Schneider, ran to the dynamo to disconnect the brushes. Schneider was not authorised to do this, but wished, doubtless to show his willingness, to his own misfortune. Instead of laying hold of the caoutchouc handle he seized the brushes with both hands. The entire current of 2,000 volts passed through his body. He was dead in a moment and had to be dragged away by violence. This misfortune occasioned an irregularity in the lighting. The director Clements instantly sent for physicians, but all attempts to restore animation were fruitless.

According to a report of the Hungarian Ministry of Trade, there were in Hungary in the year 1889.

altogether 10 municipal central telephone stations in work with the following result :—

adds a second disturbing element to the vibration due to the recoil.

The Crocker-Wheeler Motor Company, of this city, were invited by the the United States Navy Department to arrange an electric firing mechanism for the Gatling gun. Several requirements had to be kept in mind in producing the design. The apparatus had to be attached to the barrel of the gun, so as to move with it. It had to be out of the sighting line, and it was necessary to dispose of it so as not to interfere with elevation or depression of the gun. The motor finally had to be adapted for operation by the electric lighting plants as installed upon the ships of war. The drawings show clearly how the problem has been attacked.

Upon the left hand side of the breech of the gun an open frame of generally rectangular outline is secured. Within it is placed the motor. This is a specially-wound motor, adapted for an electromotive force of 80 volts, and a current of 3 to 3½ ampères intensity. This, it will be seen, represents the absorption of a

#### FIRING GATLING GUNS BY ELECTRICITY.

#### ELECTRICALLY-FIRED GATLING GUN.

THE above illustration from the *Scientific American*, shows a new application of the electric motor, in which it is caused to operate a Gatling gun. This well-known type of mitrailleuse has been placed on many of the United States naval vessels, and represents a very powerful weapon for repelling attacks and for general fighting work at close quarters.

Hitherto the Gatling gun has not been automatic. The loading is effected by turning a crank attached to the breech mechanism of the piece. As this causes the barrels to rotate, they are discharged one at a time. Ten barrels are comprised in the piece, so that for each revolution 10 shots are delivered. While one man turns the crank, a second man, holding the tail stock or lever, may be employed in directing and aiming the piece, if continual change of direction is needed. While this character of manipulation is often required, and is that by which rapid-firing guns should perform the greatest execution, it has attendant difficulties. The turning of the crank inevitably causes the piece to oscillate, and

little over one-third electric horse-power. The efficiency of the motor is placed at over 80 per cent. The spindle of the armature, which in general terms runs horizontally and at right angles to the axis of the gun, carries a pinion which engages a large gear wheel. The latter is enclosed in the cylindrical or disk-like case, which is seen next to the motor by the side of the breech. The spindle of the large gear wheel is prolonged across the end of the gun barrel, and carries a worm at its end. This gears into a worm wheel on the working spindle of the gun.

This double reduction of speed causes the operation of the gun at about 150 revolutions per minute, giving 1,500 discharges. This rate is rather high for general practice, and can be considerably reduced.

A small switch is provided for turning the current on and off. The artillerist, after starting the motor, is free to swing the piece in any direction. This he can do without interference from a second operator, and the gun is undisturbed by the shaking due to the turning of the crank.

Between the motor and the large gear wheel is a clutch, by which the motor can be connected or disconnected from the breech mechanism. The crank by

which the piece is worked by hand under the former conditions, is arranged for rapid disconnection or re-connection. This provides for injury to the electric apparatus. If the latter becomes disabled, or if its connections are severed, the clutch can be thrown open and the handle connected, when the gun will be ready for operation by hand. This change takes only a few seconds. This application of electricity is of special interest, as bringing the Gatling gun into the rank of automatically fired artillery.

### POSTAL TELEGRAPH CLERKS AND THE "QUIN TESTIMONIAL."

A CELEBRATION somewhat on the lines of the now familiar Postal Jubilee ceremonial has to be noticed during the past week, when the Postmaster-General, in what a contemporary terms the "happiest of veins," contributed a not uninteresting speech on the subject of the wonderful spread of postal and telegraphic business in Great Britain during the last 20 years.

The laying of the memorial stone of the vast building in Aldersgate Street, henceforth to be known as the General Post Office North, and which will, it is expected, be finished in 1893, brought together a crowd of officially sympathetic and officially enthusiastic supporters of the Postmaster-General.

Doubtless much complacency distinguished the bearing of those fortunate individuals present who were referred to as the recipients of honours conferred on them by Her Most Gracious Majesty the Queen, and in the eyes of those whom curiosity, if no stronger motive, had attracted to the spot, they would be regarded possibly with feelings not unmingled with awe.

With regard to the matter of honours, while such things as C.B.'s, K.C.B.'s, and G.C.B.'s remain symbolical of the expressions of a sovereign's, and perhaps a nation's favour, it may be well to remind those who in civil capacities have been fortunate enough to secure a place in the struggle for social distinction that much of that distinction, especially in the Civil Service, is due to the ever-increasing labour and responsibility thrust upon those who have to battle for a bare existence, many degrees lower down in the social scale. Military and naval men, as a rule, do not forget that their "ribbon, stars, and a' that," are in a great measure the recognition of the concentrated efforts of phalanxes of their fellow-countrymen, and this is equally applicable to the numerous army of civil servants.

In this direction few probably of the complacent and successful hearers of the Postmaster-General's speech troubled themselves, and no thoughts of the discreditable labour turmoils of the postal administration, which will render the year 1890 famous, were visible on their smiling countenances.

Interested as scientific men are generally in the progress of telegraphy and its practical application to commerce, the amazing progress of the Postal Telegraph Service, and the ever-increasing assimilation of its advantages to the general interests of the community at large, may well occasion them surprise. It seems tolerably certain that the Telegraph Service, given fair opportunities, will outstrip the sister services; the statistics quoted by the Postmaster-General, indicating a greater percentage of increase of public patronage than is shown by the other services referred to by him.

The growth of the Central Telegraph Department alone since 1870 is, indeed, a revelation, and it has been asked, and not without reason, why the able and invaluable labours of the veteran chief, or Controller, have not received decorative recognition. Perhaps this honour is withheld through the agitation which exists in the Telegraph Service, and the failure to raise three spontaneous Jubilee cheers on a recent occasion.

While the memorial stone display was taking place in the chaotic wilds of the General Post Office North, a display of another nature was being made in the

windows of a well-known City photographer, not 100 yards from the General Post Office, and the peculiar character of the latter display formed the subject of articles in several of the evening papers.

Readers of this journal, who have seen articles on the agitation in the Postal Telegraph Service in these columns, may remember the case of a telegraph clerk named Quin, who was dismissed for "talking on the wire," a breach of minor rules, no doubt, but hardly one necessitating such severe and unprecedented punishment. The unanimous feeling amongst telegraph clerks appears to be that Quin—an executive committee man, and appointed to that position almost against his will by the staff at the Central Telegraph Department—was made a martyr, and no doubt, in their opinion, an altogether unnecessary edition of the Israelitish scapegoat, which had to bear the responsibility of a nation's iniquity. As has already been said in these columns, of admittedly irreproachable official character—as well as socially unblemished in that respect, for there is a double distinction here—intelligent, honourable, and honest, Quin's efforts, which largely helped to improve the already comfortable affluence of those who afterwards sat in judgment on him, as well as helping to secure concessions to the staff, only brought to himself censure and dismissal.

It can easily be understood that popular feeling quickly determined that Quin should not go into the world to start life afresh and empty-handed. Though it has been said that "the herd of mankind can hardly be said to think," and that "their notions are almost all adoptive," such does not appear to have been the case in the matter under notice. Subscription lists were quietly but expeditiously sent round the Central Telegraph Department, and a most praiseworthy and generous unanimity resulted in the raising of the magnificent sum of £350 in a very short time. The matter was also taken up in the provinces, with the result that £150 were realised with gratifying alacrity. Nothing approaching this sum has ever been subscribed before, though charity, philanthropy and generosity are by no means strangers to the Telegraph Service, but then on the other hand there has never been a case in which individual and collective responsibility has been involved to so great an extent. The presentation of this handsome sum was to have taken place in public. Notice was given to the "authorities," who gave unmistakable proof that their peculiar code of honour would be outraged by what many in a thoroughly dispassionate neutrality of mind would consider an enthusiasm of noble kindness and gratitude. Equally impartial people will wonder where the right has been acquired which permits of interference with, and practical subversion of, one of our most cherished social institutions—the right of public meeting for the purpose of presenting a testimonial, or the discharge of any other social ceremonial. Possibly the St. Martin's-le-Grand officials may have acquired such rights by methods satisfactory to themselves, but it may be doubted whether they would meet with the approval of the public at large. There being no desire, we suppose, on the part of the Telegraph Clerks to bring about a display of hostility to the Postmaster-General or the permanent officials the projected meeting was abandoned, and the Quin testimonial—which took the form of a tastefully illuminated and kindly worded address, a silver medal, specially struck, and a sum of nearly £500—was presented to the recipient privately.

Into the feelings which must have thrilled the heart of Quin, it is not necessary to enter at any length. The substantial sympathy of his former colleagues will make up something akin to ample recompense for the prospects nipped at the best in the stem only—and it must surely be felt that there were the grandest and most genuine reasons for this extraordinary display of practical and thorough friendship, and that Quin was in every way worthy of the reciprocal loyalty of his friends.

However, happy in the possession of a temperament and a heart not easily daunted, Quin has apparently lost but little time in putting the whole matter before

the eyes of the public in a way which has utterly defeated the desires of those who longed for his relegation to public and commercial obscurity.

The latest phase of the matter will strongly remind some of our readers of the tinker who, in mending one hole, made two fresh ones—in the tinker's case the result was premeditated, but the action of the authorities in the Quin affair has led to the whole thing stepping into the broad light of public opinion, for boldly displayed, in the spacious window of the friendly City photographer's premises may be seen the testimonial from the Postal Telegraph staff of the United Kingdom and the silver presentation medal, together with large and plainly worded cards announcing the circumstances which have led to their exhibition before the eyes of the public.

### RECENT RESEARCHES ON THE ELECTRICAL CONDUCTIVITY OF CERTAIN LIQUIDS.

IN our issue of the ELECTRICAL REVIEW for October 31st, we called attention to some recent researches on the electrical conductivity of certain saline solutions, giving a brief sketch of the work which is being carried on in this direction by some of the French and German scientists. Another German has now entered this interesting field of investigation. Herr F. J. Wershoven has lately been examining the electrical conductivity of aqueous solutions of the cadmium salts. We give a brief *resumé* of his more important results.

Wershoven undertook the study of solutions of the chloride, bromide, iodide, nitrate, and sulphate of cadmium, also of potassium-cadmium oxide; these were examined within wide limits of concentration and temperature.

It was found that the temperature-coefficients of all these salts of cadmium approximated very closely in extremely dilute solutions to 2·3 per cent. per degree. To this statement, however, the iodide and double iodide of cadmium are exceptions.

The variations of electrical conductivity with the variations of temperature may, in the case of concentrated solutions, be expressed by a linear equation for the chloride, iodide, and double iodide of cadmium; an equation of the second degree is, however, required, in order to express these variations in the case of the other salts of cadmium.

Grottrian's figures for electrical conductivity are well known, and have been very generally relied upon, but Wershoven fails to confirm them, and is of opinion that they must not be so implicitly trusted as they have been. He finds that there is sometimes so large a difference as 10 per cent. between his results and Grottrian's numbers, and suggests that possibly the preparations used by the latter were not in a sufficient state of purity.

Wershoven enters into a long discussion of the results with respect to molecular conductivity, the rate of transference of the ions, and the supposed complexity of the salt molecules. This is not capable of useful abstraction for our readers; we therefore merely give the conclusions arrived at.

Arrhenius held that in the case of cadmium nitrate the inactive molecules are not complex, but that in the other salts of this metal they do possess a certain degree of complexity. This view is supported by Wershoven, who finds it to agree with the results deduced from his own experiments.

Combined with the well-known values of Kohlrausch for the speed of migration of the anions (a), chlorine (b), bromine (c), iodine, and (d) the radicle NO<sub>3</sub>, the numbers obtained for extreme states of dilution give the following speeds of the cadmium ion:—

$$\left. \begin{array}{l} \text{For (a) speed} = 49\cdot2 \\ \text{      (b)      } = 50\cdot9 \\ \text{      (c)      } = 49\cdot3 \\ \text{      (d)      } = 53\cdot7 \end{array} \right\} \text{Mean} = 51.$$

The speeds of other ions expressed in the same units are for the following bivalent metals:—

Barium :	speed	...	...	=	51
Zinc :	"	...	...	=	51
Magnesium :	"	...	...	=	53

During the course of his investigation Wershoven found that a freshly platinised platinum electrode, when immersed in a solution of iodide of potassium, had the effect of colouring the solution at first yellow, and then in a few minutes, pink.

This interesting result is not, as might perhaps be reasonably supposed, due to the liberation of iodine, for Wershoven could not obtain the characteristic blue colouration with the usual starch-paste test. He considers that it is accounted for by the formation of platinum tetriodide, which dissolves in the solution of potassium iodide. The reaction seems capable of expression by the following equation:—

In order to obtain this effect it is not necessary to previously immerse the platinum electrode in a solution of platinum chloride; hydrochloric acid alone effects the reaction which indeed may be used as a most delicate test for this acid: it will even give results when the usual reagent nitrate of silver gives no turbidity whatever.

In applying this test, Wershoven recommends the following method of procedure, which we give, thinking it might be of advantage to some of our readers who may be engaged upon certain branches of delicate research.

The freshly platinised electrode is washed in distilled water and then dipped repeatedly into potassium iodide solution until it no longer produces any pink colouration. It is then thoroughly washed with aqueous alcohol, then with distilled water, after which it is placed for some time in the solution which is suspected of containing hydrochloric acid. The electrode is again subjected to careful washing with water and then immersed in a dilute solution of potassium iodide. After a little while the pink colour will appear. Neither ordinary chloride nor hydrobromic or other acid give the colouration, so the test is quite unique.

### THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.

(Continued from page 633.)

#### SPECIFICATIONS OF ELECTRO-MAGNETS.

One frequently comes across specifications for construction which prescribe that an electro-magnet shall be wound so that its coil shall have a certain resistance. This is an absurdity. Resistance does not help to magnetise the core. A better way of prescribing the winding is to name the ampère-turns and the temperature limit of heating. Another way is to prescribe the number of watts of energy which the magnet is to take. Indeed it would be well if electricians could agree upon some sort of figure of merit by which to compare electro-magnets, which should take into account the magnetic output, *i.e.*, the product of magnetic flux into magnetomotive force—the consumption of energy in watts, the temperature rise, and the like.

#### AMATEUR RULE ABOUT RESISTANCE OF ELECTRO-MAGNET AND BATTERY.

In dealing with this question of winding copper on a magnet core, I cannot desist from referring to that rule which is so often given, which I often wish might disappear from our text books; the rule which tells you in effect that you are to waste 50 per cent. of the energy you employ. I refer to the rule which states that you will get the maximum effect out of an electro-magnet if you so wind it that the resistance is equal to the resistance of the battery you employ; or that if you have a magnet of a given resistance you ought to employ a battery of the same resistance. What is the meaning of this rule? It is a rule which is absolutely meaningless unless in the first case the volume of the coil is prescribed once for all, and you cannot alter it, or unless once for all

\* Cantor Lecture. Delivered before the Society of Arts, February 3rd, 1890.

the number of battery elements that you can have is prescribed. If you have to deal with a fixed number of battery elements, and you have to get out of them the biggest effect in your external circuit, and cannot beg, buy, or borrow, any more cells, it is perfectly true that, for steady currents, you ought to group them so that their internal resistance is equal to the external resistance that they have to work through; and then, as a matter of fact, half the energy of the battery will be wasted, but the output will be a maximum. Now that is a very nice rule indeed for amateurs, because an amateur generally starts with the notion that he does not want to economise in his rate of working; it does not matter whether the battery is working away furiously, heating itself, and wasting a lot of power; all he wants is to have the biggest possible effect for a little time out of the fewest cells. It is purely an amateur's rule, therefore, about equating the resistance inside to the resistance outside. But it is absolutely fallacious to set up any such rule for serious working; and not only fallacious, but absolutely untrue if you are going to deal with currents that are going to be turned off and on quickly. For any apparatus like an electric bell, or rapid telegraph, or induction coil or any of those things where the current is going to vary up and down rapidly, it is a false rule, as we shall see presently. What is the real point of view from which one ought to start? I am often asked questions by, shall I say, amateurs as well as by those who are not amateurs, about prescribing the battery for a given electro-magnet, or prescribing an electro-magnet for a given battery. Again, I am often told of cases of failure in which a very little common sense rightly directed might have made a success. What one ought to think about in every case is not the battery, not the electro-magnet, but *the line*. If you have a line, then you must have a battery and electro-magnet to correspond. If the line is short and thick, a few feet of good copper wire, you should have a short thick battery (a few big cells, or one big cell), and a short thick coil on your electro-magnet. If you have a long thin line, miles of it, say, you want a long thin battery (small cells, and a long row of them) and a long thin coil. That is then our rule; for a short thick line, a short thick battery, and a short thick coil; for a long thin line, a long thin battery; and electro-magnet coils to match. You smile: but it is a really good rule that I am giving you; vastly better than the worn-out amateur rule.

But, after all, my rule does not settle the whole question, because there is something more than the whole resistance of the circuit to be taken into account. Whenever you come to rapidly acting apparatus, you have to think of the fact that the current, while varying, is governed not so much by the resistance as by the inertia of the circuit—its electro-magnetic inertia. As this is a matter which will claim our especial attention hereafter, I will leave battery rules for the present, and proceed with the question of design.

#### FORMS OF ELECTRO-MAGNETS.

This at once leads us to consider the classification of forms of magnets. I do not pretend to have found a complete classification. There is a very singular book written by Mons. Nicklés, in which he classifies under 37 different heads all conceivable kinds of magnets, bidromic, tridromic, monocnemic, multidromic, and I do not know how many more; but the classification is both unmeaning and unmanageable. For my present purpose I will simply pick out those which come under three or four heads, and deal separately with others that do not quite fit under any of the four categories.

**Bar Electro-magnets.**—In the first place there are those which have a straight core, of which there are several specimens on the table here.

**Horseshoe Electro-magnets.**—Then there are the horseshoes, of which some are of one piece bent, and others are of the more frequent shape made of three pieces.

**Iron-clad Electro-magnets.**—Then from the horseshoes I go to those magnets in which the return circuit of the iron comes back outside the coil either from one end or the other, or from both ends, sometimes in the form of an external tube or jacket, sometimes merely with a parallel return yoke, or two parallel return yokes. All such magnets I propose to call—following the fashion that has been adopted for dynamos—iron-clad electromagnets. One of them, the jacketed electromagnet, is shown in fig. 12 and there are others not so well known. There is one used by Mr. Cromwell Varley, in which a straight magnet is placed between a couple of iron caps, which fit over the ends, and virtually bring the poles down close together; the circular rim of one cap being the north pole, and that of the other cap being the south pole, the two rims being close together. That plan of course produces a great tendency to leak across from one rim to the other all round. The advantages, as well as the disadvantages, of the jacketed magnet I alluded to in my last lecture, when I pointed out to you that for all action at a distance it is far better not to have an iron-clad return path, whereas for action in contact the iron-clad magnet was distinctly a very good form. In one form of iron-clad magnet the end of the straight central core is fixed to the middle of a bar of iron, the ends of which are bent up and brought flush with the top of the bobbin, making thus a tripolar magnet, with one pole between the other two. The armature in this form is a bar which lies right across the three poles. There is an example of this excellent kind of electromagnet applied in one of the forms of electric bell indicator made by Messrs. Gent, of Leicester.

Then, besides these three main classes—the straight bar, the horseshoe, and the iron-clad—there is another form which is so useful, and so commonly employed in certain work, that it deserves

to have a name of its own. It is that called by Count Du Moncel the *aimant boîteux*, or club-footed magnet (fig. 50). It is a horseshoe in fact, with a coil upon one pole and no coil upon the other. The advantage of that construction is simply, I suppose, that you will save labour—you will only have to wind the wire on one pole instead of two. Whether that is an improvement in any other sense is a question for experiment to determine; but on which theory perhaps might now be able to say something. Count Du Moncel, who made many experiments on this form of magnet, ascertained that there was for an equal weight of a copper a slight falling off in power with the club-footed magnet. Indeed one might almost predict, for a given weight of copper, if you wound all in one coil only, you will not make as many turns as if you wound it in two; the outer turns on the coil being so much larger than the average turn when wound in two coils. Consequently the number of ampère turns with a given weight of copper would

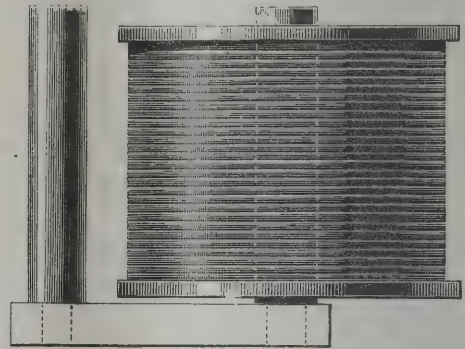

FIG. 50.—CLUB-FOOTED ELECTRO-MAGNET.

be rather smaller, and you would require more current to bring the magnetising power up to the same value as with the two coils. At the same time the one coil may be produced a little more cheaply than the two; and, indeed, such electro-magnets are really quite common, being largely used, for the sake of cheapness and compactness, in indicators of electric bells.

Du Moncel tried various experiments about this form to find whether it acted better when the armature was pivoted over one pole or over the other, and found it worked best when the armature was actually hinged on to that pole which comes up through the coil. He made two experiments, trying coils on one or other limb, the armature being in each case set at an equal distance. In one experiment he found the pull was 35 grammes, with an armature hinged on to the idle pole, and 40 grammes when it was hinged on to the pole which carried the coil.

Another form of electro-magnet, having but one coil, is used in the electric bells of church-bell pattern, of which Mr. H. Jensen is the designer. In Jensen's electro-magnet a straight cylindrical core receives the bobbin for the coil, and after this has been pushed into its place, two ovate pole-pieces are screwed upon its ends, serving thus to bring the magnetic circuit across the ends of the bobbin, and forming a magnetic gap along the side of the bobbin. The armature is a rectangular strip of soft iron, about the same length as the core, and is attracted at one end by one pole-piece, and at the other end by the other.

#### EFFECT OF SIZE OF COILS.

Seeing that the magnetising power which a coil exerts on the magnetic circuit which it surrounds is simply proportional to the ampère turns, it follows that those turns which lie on the outside layers of the coil, though they are further away from the iron core, possess precisely equal magnetising power. This is strictly true for all closed magnetic circuits; but in those open magnetic circuits where leakage occurs it is only true for those coils which encircle the leakage lines also. For example, in a short bar electro-magnet, of the wide turns on the outer layer, those which encircle the middle part of the bar do enclose all the magnetic lines, and are just as operative as the smaller turns that underlie them; whilst those wide turns which encircle the end portions of the bar are not so efficient, as some of the magnetic lines leak back past these coils.

#### EFFECT OF POSITION OF COILS.

Among the other researches which Du Moncel made with respect to electro-magnets, was one on the best position for placing the coil upon the iron core. This is a matter that other experimenters have examined. In Dub's book, "Electro-magnetism," to which I have several times referred, you will also find many experiments on the best position of a coil; but it is perhaps sufficient to narrate a single example. Du Moncel had four pairs of bobbins made of exactly the same length, and with 50 metres of wires on each, one pair was 16 centimetres long, another pair 8 centimetres, or half the length, with not quite so many turns, because of course the diameter of the outer turns was larger, one 4 centimetres in length and another 2 centimetres. These were tried both with bar magnets and horseshoes. It will suffice perhaps to give the result of the horseshoe. The horseshoe was made long enough—16 centimetres only, a little over 6 inches long—to carry the longest coil. Now when the compact coils 2 centimetres long were used, the pull on the armature at a distance away of 2 millimetres (it was always the same, of course, in the experiments) was 40 grammes. Using the same

weight of wire, but distributed on the coils twice as long, the pull was 55 grammes. Using the coils 8 centimetres long, it was 75 grammes; and using the coils 16 centimetres long, covering the length of each limb, the pull was 85, clearly showing that, where you have a given length of iron, the best way of winding a magnet to make it pull with its greatest pull, is not to heap the coil up against the poles, but to wind it uniformly, for this mode of winding will give you more turns, therefore more ampère turns, therefore more magnetisation. An exception might, however, occur in some case where there is a large percentage of leakage. With club-footed magnets results of the same kind are obtained. It was found in every case that it was well to distribute the coil as much as possible along the length of the limb. All these experiments were made with a steady current. It does not follow, however, because winding the wire over the whole length of core is best for steady currents that it is the best winding in the case of a rapidly varying current; indeed, we shall see that it is not.

#### EFFECT OF SHAPE OF SECTION.

So far as the carrying capacity for magnetic lines is concerned, one shape of section of cores is as good as another; square or rectangular is as good as round if containing equal sectional area. But there are two other reasons, both of which tell in favour of round cores. First, the leakage of magnetic lines, from core to core is, for equal mean distances apart, proportional to the surface of the core; and the round core has less surface than square or rectangular of equal section. All edges and corners, moreover, promote leakage. Secondly, the quantity of copper wire that is required for each turn will be less for round cores than for cores any other shape, for of all geometrical figures of equal area the circle is the one of the least periphery.

#### EFFECT OF DISTANCE BETWEEN POLES.

Another matter that Du Moncel experimented upon, and Dub and Nicklès likewise, was the distance between the poles. Dub considered that it made no difference how far the poles were apart. Nicklès had a special arrangement made which permitted him to move the two upright cores or limbs, 9 centimetres high, to and fro on a solid bench or yoke of iron. His armature was 30 centimetres long. Using very weak currents he found the effect best when the shortest distance between the poles was 3 centimetres; with a stronger current 12 centimetres; and with his strongest current nearly 30 centimetres. I think leakage must have a deal to do with these results. Du Moncel tried various experiments to elucidate this matter, and so did Prof. Hughes, in an important, but too little-known, research which came out in the *Annales Télégraphiques*, in the year 1862.

#### RESEARCHES OF PROFESSOR HUGHES.

His object was to find out the best form of electro-magnet, the best distance between the poles, and the best form of armature for the rapid work required in Hughes's printing telegraphs. One word about Hughes's magnets. This diagram (fig. 51) shows the

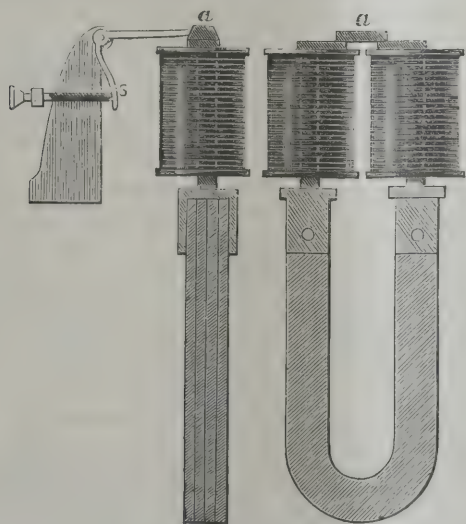

FIG. 51.—HUGHES'S ELECTRO-MAGNET.

form of the well-known Hughes's electro-magnet. I feel almost ashamed to say these words "well-known," because although on the continent everybody knows what you mean by a Hughes's electro-magnet, in England scarcely anyone knows what you mean. Englishmen do not even know that Prof. Hughes has invented a special form of electro-magnet. Hughes's special form is this:—A permanent steel magnet, generally a compound one, having soft iron pole pieces, and a couple of coils on the pole pieces only. As I have to speak of Hughes's special contrivance amongst the mechanisms that will occupy our attention next week, I only now refer to this magnet in one particular. If you wish a magnet to work rapidly, you will secure the most rapid action not when the coils are distributed all along but when they are heaped up near, not necessarily entirely on, the poles. Hughes made a number of researches to find out what the right length and thickness of these pole pieces should be. It was found an advan-

tage not to use too thin pole pieces, otherwise the magnetism from the permanent magnet did not pass through the iron without considerable reluctance, being choked by insufficiency of section; also not to use too thick pieces, otherwise they presented too much surface for leakage across from one to the other. Eventually a particular length was settled upon, in proportion about six times the diameter, or rather longer. In the further researches that Hughes made he used a magnet of shorter form, not shown here, more like those employed in relays, and with an armature from 2 to 3 millimetres thick, 1 centimetre wide, and 5 centimetres long. The poles were turned over at the top towards one another. Hughes tried whether there was any advantage in making those poles approach one another, and whether there was any advantage in having as long an armature as 5 centimetres. He tried all different kinds, and plotted out the results of observations in curves, which could be compared and studied. His object was to ascertain the conditions which would give the strongest pull, not with a steady current but with such currents as were required for operating his printing telegraph instruments; currents which lasted but one to twenty hundredths of a second. He found it was decidedly an advantage to shorten the length of the armature, so that it did not protrude far over the poles. In fact he got a sufficient magnetic circuit to secure all the attractive power that he needed, without allowing as much chance of leakage as there would have been had the armature extended a longer distance over the poles. He also tried various forms of armature having various cross sections.

#### POSITION AND FORM OF ARMATURE.

In one of Du Moncel's papers on electromagnets\* you will also find a discussion on armatures, and the best forms for working in different positions. Amongst other things in Du Moncel you will find this paradox; that whereas using a horseshoe magnet with flat poles, and a flat piece of soft iron for armature, it sticks on far tighter when put on edgewise; on the other hand, if you are going to work at a distance, across air, the attraction is far greater when it is set flatways. I explained the advantage of narrowing the surfaces of contact by the law of traction,  $B^2$  coming in. Why should we have for an action at a distance the greater advantage from placing the armature flatway to the poles? It is simply that you thereby reduce the reluctance offered by the air gap, to the flow of the magnetic lines. Du Moncel also tried the difference between round armatures and flat ones, and found that a cylindrical armature was only attracted about half as strongly as a prismatic armature, having the same surface when at the same distance. Let us examine this fact in the light of the magnetic circuit. The poles are flat. You have at a certain distance away a round armature; there is a certain distance between its nearest side and the polar surfaces. If you have at the same distance away a flat armature having the same surface, and, therefore, about the same tendency to leak, why do you get a greater pull in this case than in that? I think it is clear that if they are at the same distance away, giving the same range of motion, there is a greater magnetic reluctance in the case of the round armature, although there is the same periphery, because though the nearest part of the surface is at the prescribed distance, the rest of the under surface is farther away; so that the gain found in substituting an armature with a flat surface is a gain resulting from the diminution in the resistance offered by the air gap.

#### POLE PIECES ON HORSESHOE MAGNETS.

Another of Du Moncel's researches† relates to the effect of polar projections or shoes—moveable pole pieces, if you like—upon a horseshoe electro-magnet. The core of this magnet was of round iron 4 centimetres in diameter, and the parallel limbs were 10 centimetres long and 6 centimetres apart. The shoes consisted of two flat pieces of iron slotted out at one end, so that they could be slid along over the poles and brought nearer together. The attraction exerted on a flat armature across air gaps 2 millimetres thick, was measured by counterpoising. Exciting this electro-magnet with a certain battery, it was found that the attraction was greatest when the shoes were pushed to about 15 millimetres, or about one quarter of the inter-polar distance apart. The numbers were as follows:—

Distance between shoes. Millimetres.	Attraction in grammes.
2 ... ..	900
10 ... ..	1,012
15 ... ..	1,025
25 ... ..	965
40 ... ..	890
60 ... ..	550

With a stronger battery the magnet without shoes had an attraction of 885 grammes, but with the shoes 15 millimetres apart, 1,195 grammes. When one pole only was employed, the attraction, which was 88 grammes without a shoe, was diminished by adding a shoe to 39 grammes!

#### CONTRAST BETWEEN ELECTRO-MAGNETS AND PERMANENT MAGNETS.

Now I want particularly to ask you to guard against the idea that all these results obtained from electro-magnets are equally applicable to permanent magnets of steel; they are not, for this simple reason. With an electro-magnet, when you put the armature near, and make the magnetic circuit better, you not only get

\* *La Lumière Electrique*, vol. ii.

† *La Lumière Electrique*, vol. iv., p. 129.

more magnetic lines going through that armature, but you get more magnetic lines going through the whole of the iron. You get more magnetic lines round the bend when you put an armature on to the poles, because you have a magnetic circuit of less reluctance, with the same external magnetising power in the coils acting around it. Therefore, in that case, you will have a greater magnetic flux all the way round. The data obtained with the electro-magnet (fig. 42), with the exploring coil, *c*, on the bend of the core, when the armature was in contact, and when it was removed, are most significant. When the armature was present it multiplied the total magnet flow tenfold for weak currents, and nearly threefold for strong currents. But with a steel horseshoe, magnetised once for all, the magnetic lines that flow around the bend of the steel are a fixed quantity, and however much you diminish the reluctance of the magnetic circuit you do not create or evoke any more. When the armature is away the magnetic lines arch across, not at the ends of the horseshoe only, but from its flanks; the whole of the magnetic lines leaking somehow across the space. When you have put the armature on, these lines, instead of arching out into space as freely as they did, pass for the most part along the steel limbs and through the iron armature. You may still have a considerable amount of leakage, but you have not made one line more go through the bent part. You have absolutely the same number going through the bend with the armature off as with the armature on. You do not add to the total number by reducing the magnetic reluctance, because you are not working under the influence of a constantly impressed magnetising force. By putting the armature on to a steel horseshoe magnet you only *collect* the magnetic lines, you do not *multiply* them. This is not a matter of conjecture. A group of my students have been making experiments in the following way. They took this large steel horseshoe magnet (fig. 52) the

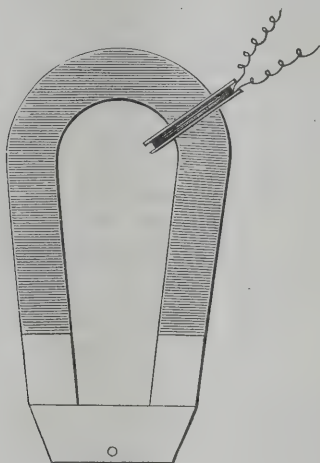

FIG. 52.—EXPERIMENT WITH PERMANENT MAGNET.

length of which from end to end through the steel is  $42\frac{1}{2}$  inches. A light narrow frame was constructed so that it could be slipped on over the magnet, and on it were wound 30 turns of fine wire, to serve as an exploring coil. The ends of this coil were carried to a distant part of the laboratory, and connected to a sensitive ballistic galvanometer. The mode of experimenting is as follows:—The coil is slipped on over the magnet (or over its armature) to any desired position. The armature of the magnet is placed gently upon the poles, and time enough is allowed to elapse for the galvanometer needle to settle to zero. The armature is then suddenly detached. The first swing measures the change, due to removing the armature, in the number of magnetic lines that pass through the coil in the particular position.

I will roughly repeat the experiment before you: the spot of light on the screen is reflected from my galvanometer at the far end of the table. I place the exploring coil just over the pole, and slide on the armature; then close the galvanometer circuit. Now I detach the armature, and you observe the large swing. I shift the exploring coil, right up to the bend; replace the armature; wait until the spot of light is brought to rest at the zero of the scale. Now, on detaching the armature, the movement of the spot of light is quite imperceptible. In our careful laboratory experiments, the effect was noticed inch by inch all along the magnet. The effect when the exploring coil was over the bend was not as great as  $\frac{1}{30000}$ th part of the effect when the coil was hard up to the pole. We are therefore justified in saying that the number of magnetic lines in a permanently magnetised steel horseshoe magnet is not altered by the presence or absence of the armature.

You will have noticed that I always put on the armature gently. It does not do to slam on the armature: every time you do so, you knock some of the so called permanent magnetism out of it. But you may pull off the armature as suddenly as you like. It does the magnet good rather than harm. There is a popular superstition that you ought never to pull off the keeper of a magnet suddenly. On investigation, it is found that the facts are just the other way. You may pull off the keeper as suddenly as you like; but you should never slam it on.

From these experimental results I pass to the special design of electro-magnets for special purposes.

"Notes on the Chemistry of Secondary Cells." By Prof. W. E. AYRTON, Vice-President; C. G. LAMB, B.Sc., and E. W. SMITH, Associates.

I.

In our paper on "The Working Efficiency of Secondary Cells," read at the meeting of this Institution in Edinburgh in July, it was stated that, "In spite of accumulators with pasted plates having been in use now for nine years, the chemical action that takes place during the different stages of the charge and discharge has only been conjectured, and, odd as it seems, no decisive experiment appears to have been made to settle this much-debated question. Various analyses have been made by different chemists of salts of lead acted on in certain ways with sulphuric acid, but apparently not of actual accumulator plates in action. We are therefore now, with the assistance of Mr. Robertson, making a complete investigation of the chemical state of the plugs of both the positive and negative plates at all stages of the charge and discharge of an 1888 E.P.S. type of accumulator in good condition." The present paper contains an account of the results thus obtained.

The cell selected to remove the plugs from had the same size as the cells employed in the investigations described in the previous communication, and was one of the batch of 50 purchased for the Central Institution about the middle of 1888. Since it first came into our possession it had never been overcharged, never been left discharged, nor permitted to send more than the maximum current allowed by the makers for cells of this size—viz., 10 amperes—and consequently, at the beginning of the present investigation in June of this year, this cell was in excellent condition.

First the cell was several times charged with a current of 9 amperes, and discharged with a current of 10, without stopping day or night, so as to bring it into what we have called its steady "working" state. The dotted curves, figs. 1 and 2, show the large charge and discharge obtained on June 28th. During the next charge, indicated by the continuous curve, fig. 1, plugs were removed from both the positive and negative plates at the points marked A, B, C, and D, when the terminal P.D. of the cell was 2.134, 2.2, 2.234, and 2.4 volts respectively. In order to remove the plugs from the positive plates, these plates were bodily removed out of the liquid, but, to prevent oxidation, the negative plates were left in the liquid, and the plugs removed in a way that will be described later on. The time occupied in removing the plugs from the two sets of plates occupied about 15 to 20 minutes on each occasion. Immediately after the removal of the plugs the positive plates were put back in position in the cell, the resistance in the circuit rapidly adjusted, if necessary, to make the charging current exactly 9 amperes, and the time variation of the P.D. at the terminals of the cell noted. The interval that elapsed while the current was broken is not shown on the curve; that is to say, the P.D. observed immediately after replacing the positive plates in the liquid and closing the circuit is plotted directly under the P.D. that was observed just before the circuit was broken, prior to the removal of the positive plates from the liquid.

We were afraid that the bodily withdrawal of the positive plates out of the liquid, combined with the removal of the plugs, on the several occasions, would produce so great a change in the conditions of the cell as to render the P.D. curve quite discontinuous. It was, therefore, as interesting as it was unexpected, to find that the terminal P.D., on restarting the normal charging current of 9 amperes, rapidly acquired the value it had before the withdrawal of the plates; so that, with the exception of the rapid rise of the P.D. on restarting the charging current, the P.D. curve obtained on June 29th was almost the same as the P.D. curve obtained on charging on the previous day.

After the cell had been charged until the terminal P.D. reached 2.4 volts, it was immediately discharged with a perfectly constant current of 10 amperes, and, as it was anticipated that the removal of the plugs would spoil the cell, it was allowed to discharge far below the normal limit. In previous discharges (the last one of which is shown by the dotted line, fig. 2), the discharge was stopped when the terminal P.D. fell to 1.85 volts. But in the discharge on June 30th, when the plugs were removed, the discharge current was kept at 10 amperes, by using auxiliary cells, until the E.M.F. of the test cell fell to nought, and even reversed. Plugs were removed from both the positive and the negative plates when the terminal P.D. was 2, 1.95, 1.85, 0.6, and nought volts, as indicated by the points A', B', C', D', and E'. The recovery of the E.M.F. on breaking the circuit was very marked, especially near the end of the discharge.

II.

#### METHOD OF OBTAINING SAMPLES OF THE PLUGS.

On the first removal of plugs corresponding with the point A fig. 1, a curved pointed glass rod was used, as shown in fig. 3, with the idea of prising out the plugs; but by this method only the surface of the positive plugs could be removed, as they were much too hard to be loosened in this way. Indeed, one of the most striking things noticed in this investigation was the firm

way in which the plugs were held in the plates of an E.P.S. cell that had been carefully used for two years. Before the next attempt was made to remove plugs corresponding with the point B, fig. 1, a straight piece of glass rod was pointed, and mounted in a wooden handle. This glass chisel was used to pierce and loosen the positive plugs, which were then driven bodily out of the grid by means of a hard wooden punch cut square to fit the holes in the grid, and which was tapped with a small mallet. The plugs on being driven out of the grid were caught in a long wooden scoop (shaped so that it could be just slipped in between the plates), and then washed by Mr. Robertson into wide-mouthed bottles containing three or four hundred c.c. of distilled water. As soon as the water cleared it was decanted off and fresh added.

handle, as shown in fig. 4. It was possible to use this method throughout for the removal of the negative plugs, as they were softer and more easily removable than the positive ones. The scoop held sufficient liquid to enable the negative plugs to be dropped into wide-necked bottles containing water without the plugs being even momentarily exposed to the air. The water in these bottles Mr. Robertson had washed free from dissolved oxygen by previously bubbling hydrogen through it for a considerable time. After the negative plugs had been put into the bottles the water was gradually decanted off from time to time, and fresh added until the liquid in the bottle was quite free from acid.

Both in the case of the positives and the negatives the top

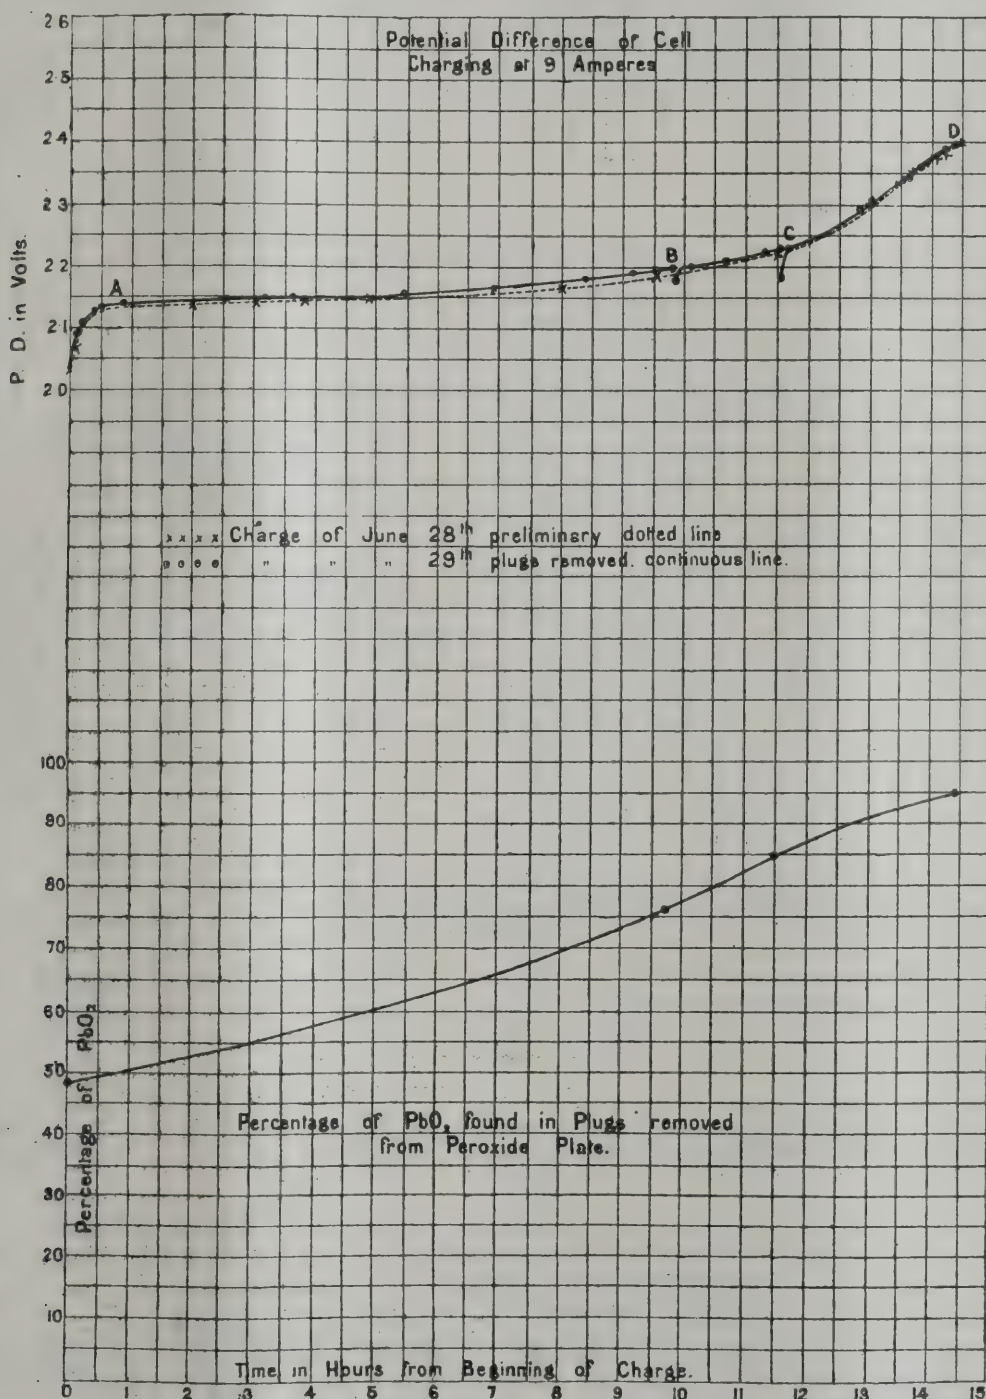

Fig. 1.

As several glass chisels were broken, and the wooden punches worn down in the removal of the plugs, the method has the disadvantage of mixing with the specimens to be analysed splinters of glass and wood, which were found difficult to remove afterwards. On the other hand, the method had the advantage of enabling specimens of the positive plugs to be removed in a comparatively short time on each occasion from the top, the middle, and the bottom of the plates.

As the negative plates were never removed from the acid, the only way to remove the plugs was by working them loose under the liquid by means of long curved glass rods pointed at the end, and by catching the plugs in a narrow wooden scoop with a long

samples were removed from the corner of the plates nearest the lug, and the bottom samples from the corner diametrically opposite, so as to obtain evidence, if possible, of any difference of current density which might exist at different parts of the plates in charging and discharging.

The plugs from the top, the middle, and the bottom of each set of plates were at each of the removals of plugs put into six separate bottles; and, to avoid the possibility of error in their subsequent identification, there was noted on the label of each the character of the plates and the position on them from which the plugs were removed, the time, the P.D., and the specific gravity of the liquid in the cell.

III.

APPEARANCE OF PLATES AT REMOVALS OF PLUGS.

The following notes were made by Mr. Robertson and ourselves at the successive removals of the plugs:—

Point c on Curve 1. Terminal P.D., 2.234 volts. Specific Gravity of Liquid, 1.201.

The previous charges increased in amount. The previous charges increased in amount.

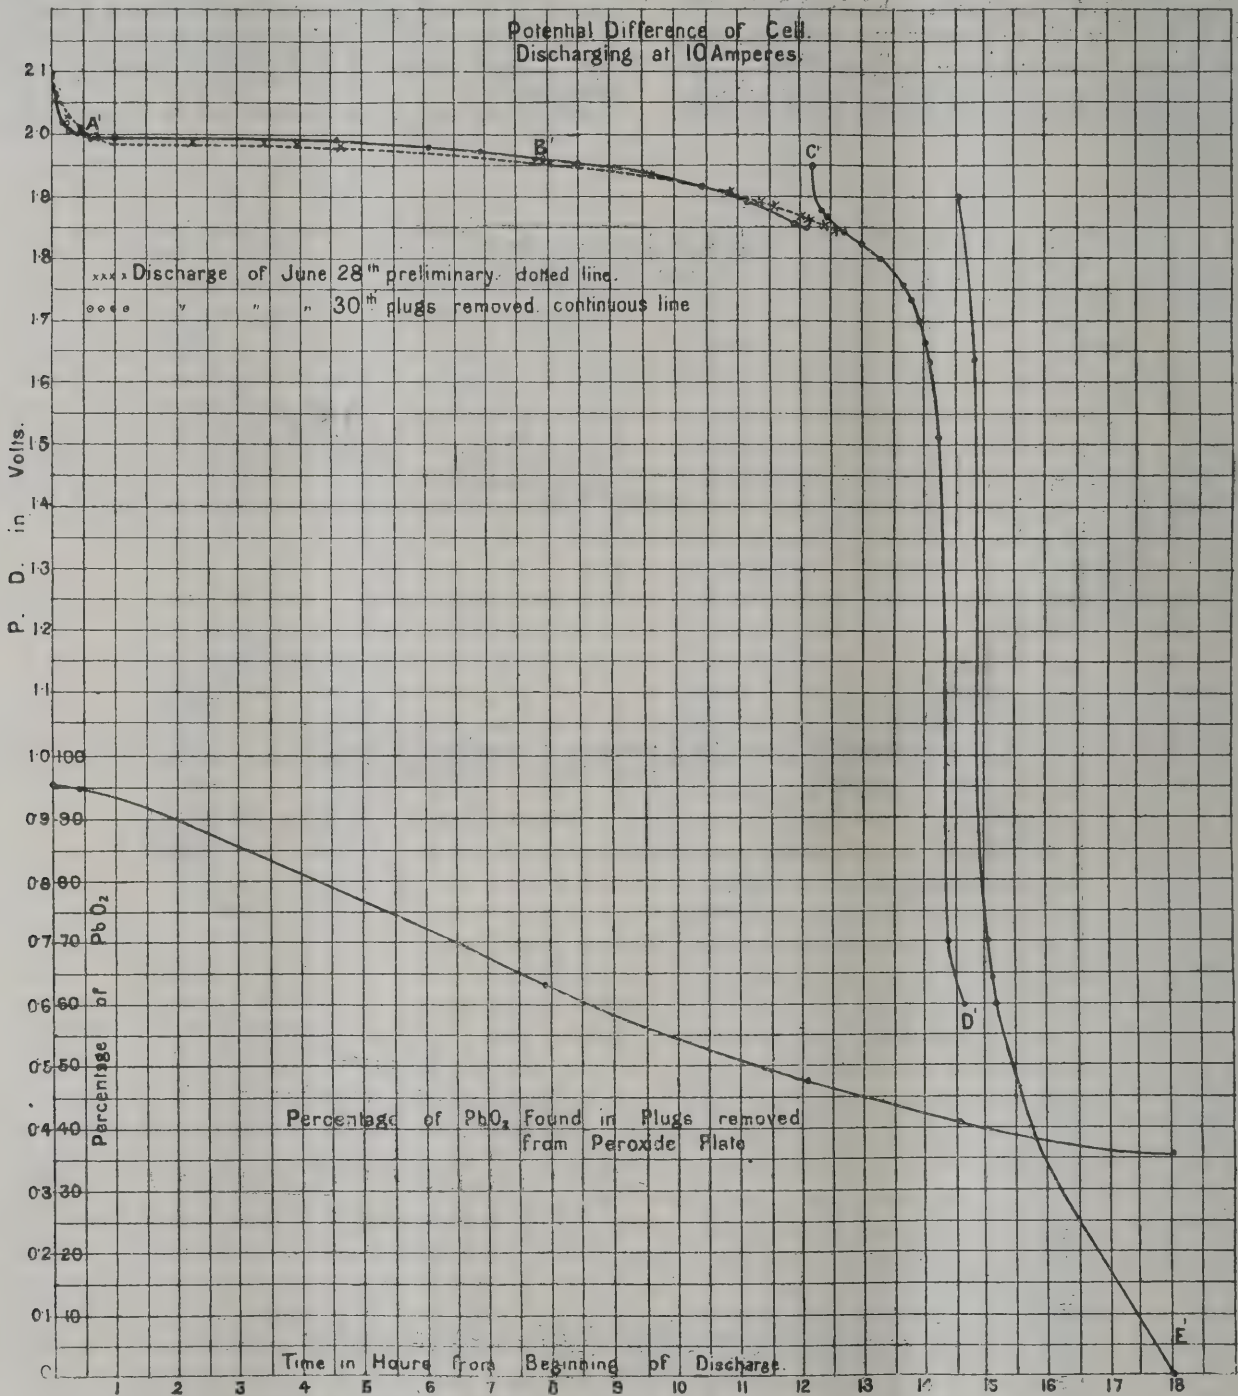

Fig 2.

CHARGING.

POSITIVE PLATES.

NEGATIVE PLATES.

Point A on Curve 1. Terminal P.D., 2.134 volts. Specific Gravity of Liquid, 1.178.

The upper part of the plates had a greyish-brown colour, and presented the appearance of being coated with a very thin film of white sulphate. The lower part of the plates was of a reddish-brown colour.

The plugs at the top were hard, while those at the bottom were quite soft.

Point B on Curve 1. Terminal P.D., 2.2 volts. Specific Gravity of Liquid, 1.198.

The plates had entirely lost their whitish appearance, and showed a uniform reddish-brown colour, darker than the previous colour of the bottom of the plates.

The plugs at the top were the softest.

The plugs both at the top and at the bottom harder than before, those at the top having hardened more than those at the bottom.

Point D on Curve 1. Terminal P.D., 2.4 volts. Specific Gravity of Liquid, 1.206.

The plates had the rich deep brown colour of lead peroxide, except where they were covered with the ebonite separators: there the colour was lighter.

The plugs at the top were slightly the softest, while those at the bottom were much the same as at the beginning.

The plugs had a brilliant metallic lustre, and looked quite silvery when first removed from the plates. The plugs at the top now were the hardest.

DISCHARGING.

POSITIVE PLATES. NEGATIVE PLATES.

Point A' on Curve 2. Terminal P.D., 1.993 volts. Specific Gravity of Liquid, 1.205.

The plugs at the top were harder than those at the bottom.

The plugs had the brilliant metallic lustre observed at the end of the charging.

Point c' on Curve 2. Terminal P.D., 1.850 volts. Specific Gravity of Liquid, 1.180.

The plugs had become much harder.

The plates had become decidedly white, and the plugs were white right through.

Point D on Curve 2. Terminal P.D., 0.6 volt. Specific Gravity of Liquid, 1.175.

The plugs had become extremely hard, especially at the bottom.

The plugs were somewhat softer.

Point E on Curve 2. Terminal P.D., 0 volt. Specific Gravity of Liquid, 1.172.

The plugs had become so hard that they splintered and bits flew about on trying to remove them.

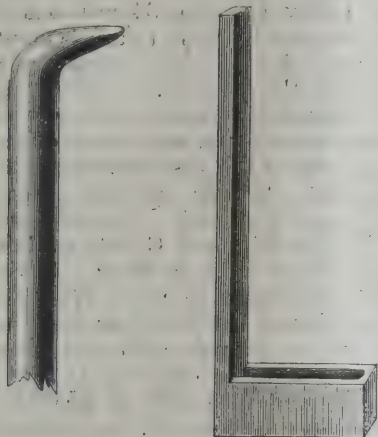

FIG. 3.

FIG. 4.

The bubbling of gas from the negative plates ceased when the terminal P.D. on discharging fell to 1.85 volts (point c' on curve 2), and it began again when the terminal P.D. fell to somewhere near zero.

FIG. 5.—Charging

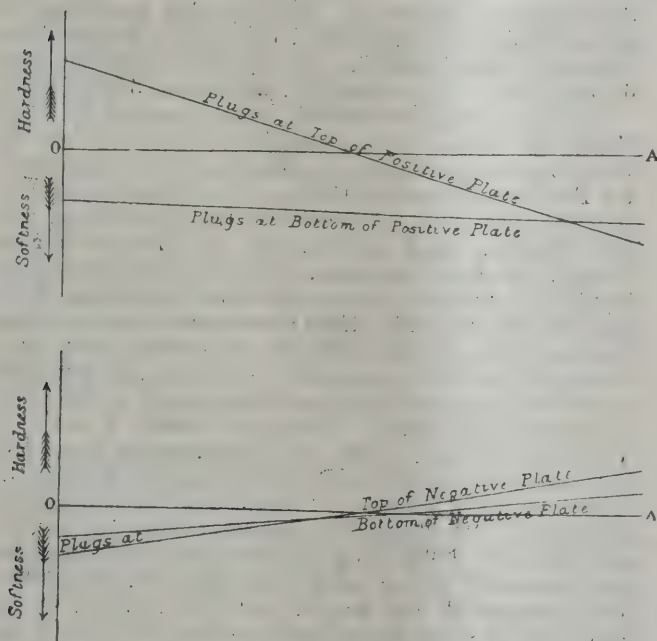

FIG. 6.

The following figures (5 and 6) give an idea of the way in which we found the hardness of the top and bottom plugs of the positive and the negative plates respectively to vary during a normal charge. The figures are not drawn to scale, as we had no standard of hardness beyond our sensations, hence the figures only profess to be qualitative sketches from which mental pictures can be obtained. Distance measured upwards from o A indicates roughly the degree of hardness; distance measured downwards the degree of softness.

It will be seen that during the charging the variation in the hardness of the plugs is far greater at the top than at the bottom of the plates, and consistently with this fact Mr. Robertson's analyses show that, on the whole, the rate of chemical action

at the top of the plates is greater than at the bottom. The difference in the hardness, however, is far more marked than the difference in the chemical action. For example, while the plugs at the top of the positive plates are, during the earlier part of the charging, much harder than those at the bottom, no such striking difference is observable in the percentage of lead peroxide contained by these plugs. The cause of this we are examining experimentally at the present time.

In order to see how far the resistance of the lead grid would tend to make the current density in the upper part of the liquid less than in the lower, as well as for the purpose of seeing how large a fraction of the whole resistance of the accumulators was due to the lead lugs and to the connections between the successive pairs of lugs, the following tests were made by three of the students—Messrs. Hobson, Lee, and Montealegre:—

Parts of the lead lugs of some of the accumulators were scraped, and on these clean spots binding screws, which had been themselves filed bright, were tightly screwed. The accumulators were allowed to send measured currents, the values of which are given in the following tables, and the P.D. between the pairs of binding screws was carefully measured with a sensitive reflecting voltmeter. The resistance of the lugs between the pairs of binding screws is then at once obtained by dividing the P.D. by the current.

(To be continued.)

### The Royal Society.

"Magnetism and Recalescence." By J. HOPKINSON, D.Sc., F.R.S.

IN my experiments, the results of which are published, "Phil. Trans," 1889, A, p. 443, I showed that recalescence and the disappearance of magnetisability in iron and steel occurred at about the same temperature. The evidence I then gave was sufficiently satisfactory, but did not amount to absolute proof of the identity of the temperatures. Osmond has shown that the temperature of recalescence depends upon the temperature to which the iron has been heated, also that it differs when the iron is heated and when it is cooled. He also showed that for some sorts of steel the heat is liberated at more than one temperature, notably that in steel with 0.29 per cent. of carbon, heat is liberated when cooling at 720° C. and at 660° C., and that with steel with 0.32 per cent. carbon there is a considerable liberation of heat before the temperature is reached when this becomes a maximum. It appeared to be desirable to obtain absolute proof that the change of magnetic property occurred exactly when heat was liberated and absorbed, and to examine, magnetically, Osmond's two temperatures of heat liberation. I have not been able to obtain samples of steel of the size I used, showing two well marked temperatures of heat liberation and absorpition, but I have a ring in which there is liberation of heat extending over a considerable range of temperature.

The samples had the form of rings. A copper wire was well insulated with asbestos, and laid in a groove running round the ring, and was covered with several layers of asbestos paper laid in the groove. This coil was used for measuring temperature by its resistance. The whole ring was served over with asbestos paper and with sheets of mica. The secondary exploring coil was then wound on, next a serving of asbestos paper and mica, and then the primary coil, and, lastly, a good serving of asbestos paper was laid over all. In this way good insulation of the secondary coil was secured, and a reasonable certainty that the temperature coil took the precise temperature of the ring, and that at any time the ring was throughout at one and the same temperature. The whole was placed in an iron pot, and this again in a Fletcher gas furnace. Observations were made of temperature as the furnace was heating, and from time to time of induction. In each case the time of observation was noted. Similar observations were made as the ring cooled, the furnace being simply extinguished. We are thus enabled to compare directly at the same instant the condition of the same ring as regards magnetism and as regards temperature, and, therefore, qualitatively as regards its absorption or liberation of heat.

The results for a ring containing 0.3 per cent. of carbon or thereabouts show that there is a considerable liberation of heat, beginning at 2 h. 12 m., temperature 715° C., and continuing to time 2 h. 22 m., temperature 660° C., being apparently somewhat slower at the end. This may, however, be only apparently slower as the furnace temperature would fall lower in relation to the ring. At time 2 h. 22 m., temperature 660° C., the rate of liberation becomes much more rapid, so much so that the temperature for a time remains almost stationary. At time 2 h. 29 m. the liberation of heat appears to have ceased, and the normal cooling to continue. Now, comparing the kicks of the galvanometer, which are proportional to the induction, it is observed that the ring begins to be magnetisable at time 2 h. 12 min., its magnetic property increases till time 2 h. 22 m.; after this point the magnetisability increases much more rapidly, and is practically fully developed at 2 h. 31 m. In this case the development of magnetic property follows precisely the whole of the liberation of heat, observed both at the temperature of about 700° C. and at 660° C. We may, therefore, be certain, that both at the higher and lower temperatures of recalescence there is magnetic change, and that the one is as much dependent on the other as the solid condition of ice is upon the liberation of heat when water solidifies. The two changes occur, not only at the same temperature, but simultaneously. A considerable magnetising force, 6.56, was taken, as it was expected and found that the magnetic property would

then be more apparent when it was in the intermediate condition between the two temperatures of recalcence.

The results of a ring containing 0.9 per cent. of carbon show that there is a slight absorption of heat at time 11 h. 17 m., temperature 710° C., with doubtful effect on the magnetism. At time 11 h. 27 m., temperature 770° C., powerful absorption of heat begins and continues to time 11 h. 55 m., temperature 808° C.; it is between these times that the magnetisability is decreasing, and at the latter time that it finally disappears. The heating was continued to about 840° C., and the flame was then put out. In cooling, heat is liberated at one point only, and in this case with a distinct rise of temperature. The recalcence begins at time 3 h. 47 m., temperature 750° C., and it is precisely at this time that the ring begins to be magnetisable. The recalcence continues to time 4 h. 8 m., and at this time, and not before it, the magnetisability practically attains a maximum. Before the last portion of the curve the ring was heated to 966° C. Here no observations were made magnetically. This part of the curve, therefore, only shows the effect of higher heating in lowering the temperature of recalcence. Unfortunately I had forgotten to record the magnetising force; it was, however, much less than in the last case, probably less than unity.

These experiments show that the liberation and absorption of heat, known as recalcence, and the change in magnetic condition, occur simultaneously. Also that in the case of steel with 0.3 per cent. of carbon both temperatures of liberation of heat are associated with change of magnetic condition.

#### Physical Society.—November 14th, 1890.

Prof. W. E. AYRTON, F.R.S., President, in the chair.

The following communication was made:—

"Tables of Spherical Harmonics, with examples of their Practical Use." By Prof. J. PERRY, F.R.S. The author defined a spherical harmonic as a homogeneous function of  $x, y, z$ , satisfying the

equation  $\frac{d^2 v}{dx^2} + \frac{d^2 v}{dy^2} + \frac{d^2 v}{dz^2} = 0$ , stated the fundamental pro-

perties of such functions, and pointed out their importance in problems on heat, electricity and hydro-dynamics. Referring to zonal harmonics (homogeneous functions of  $(x^2 + y^2)^{1/2}$  and  $z$ ), he showed that these harmonics are symmetrical with respect to the axis of  $z$ , and might be expressed as functions of the angle ( $\theta$ ) which the line joining the point  $(x, y, z)$  to the origin makes with the axis of  $z$ , multiplied by  $r^i$ ; where  $r$  is the radius vector and  $i$  the degree of the homogeneous function. These functions of  $\theta$  are called zonal surface harmonics, and are designated by  $P_0, P_1, P_2$ , &c., according to the degree of the function, and it was the values of these quantities which form the tables brought before the society. The tables comprise the values of  $P_1$  to  $P_8$ , and are calculated to four places of decimals and for every 1° between 0° and 90°.

As an example of such tables, the case of a spherical surface covered with attracting matter whose density varied as the square of its distance from a diametral plane, was taken. It was required to find the potential both outside and inside the sphere, and to determine the equipotential surfaces and lines of force. The potentials inside (A) and outside (B) were shown to be given by

$$\frac{A}{\pi} = 8 + \frac{16}{5} r^2 P_2 \text{ and } \frac{B}{\pi} = \frac{8}{r} + \frac{16}{5} \frac{1}{r^3} P_2 \text{ respectively.}$$

By giving A and B definite values and choosing values of  $r$ , the corresponding  $P_2$  can be calculated and the value of  $\theta$  determined from the tables. Hence any equipotential surface can be easily determined and lines drawn to cut these surfaces orthogonally are the lines of force.

Another problem which had been tried consisted in finding the directions of the lines of force near a circular coil of rectangular cross-section when an electric current circulates in the coil. This was treated approximately by first calculating the potential at 6 points along the axis in the neighbourhood of the coil and then finding by Gauss' method the coefficients,  $A_0, A_1, A_2$ , &c., of an expression in ascending powers of  $z$ , which agreed with the calculated potentials at the points chosen. The formula

$$V = A + A_1 r P_1 + A_2 r^2 P_2 + \text{&c.},$$

or its corresponding expression in inverse powers of  $r$  was then assumed to give the potential at any point in the space considered. By giving  $v$  definite values, a series of equipotential surfaces were determined and the lines of force drawn. On putting the calculations to the test of experiment, the approximate solution of this very difficult problem was found to be very nearly correct.

**The John Pender Gold Medal.**—The Electrical Engineering Gold Medal, presented annually by Sir John Pender, K.C.M.G., through Prof. Jamieson, to the Glasgow and West of Scotland Technical College, has been gained by Arthur H. Allen, who, besides taking the first place in all his college classes, took the first place in the kingdom with first class honours at the Science of Arts Public Examinations, and first class honours at the City and Guilds of London Institute Technological Examinations.

#### CITY AND GUILDS OF LONDON INSTITUTE.

THE annual distribution of prizes and certificates gained by students attending the various colleges of the Institute, took place at Clothworkers' Hall last Wednesday evening. The Right Hon. the Lord Mayor presided, and, in the course of his opening remarks, said it was both his duty and privilege to take part in so important a work as encouraging the spread of technical education. The question had become of vital importance, and it was only too evident that in the past elementary education had been of too academical a character; book-learning had been sought after, while the more important training of hand and eye had been greatly neglected. With the population increasing rapidly, very likely reaching 34 millions at the next census, it was impossible to find employment for all in this country, and while it was absolutely necessary that we should look to the colonies, it was important to remember that for colonists clerks were not required, but bricklayers and carpenters, and others who could use tools and make use of the vast resources nature placed at their disposal. If our national supremacy was to be maintained, technical education was essential to that end, and the City and Guilds of London Institute had been doing what it could. In September of last year there were twice as many applications for admission to the Central Institution as there had been the year before, and to provide sufficient accommodation for the increased number of students the laboratories were being enlarged at a cost of £5,000. Important researches had been carried out, one worthy of mention being that of Prof. Ayrton and his third-year students, on the "Efficiency of Secondary Cells." At Finsbury College the number which had passed the entrance examination was in excess of the number which the college could accommodate, and extensions had been rendered necessary. As a preliminary and temporary measure, a warehouse had been rented, into which the mechanical department would have to move. At the South London School of Technical Art there were at present 103 students, against 78 last year. At the Technological examinations, held by the Institute, over 6,000 students were examined, while over 3,000 passed.

The prizes and certificates were presented by Lord Cross, the names of the students being read out by Prof. Unwin for Central Institution, Prof. Thompson for Finsbury Technical College, Mr. Sparks, superintendent of studies, for the South London School, and Mr. Burdett, head master, for the Leather Trades School. The Lady Mayoress, who was present, smilingly handed the prizes to the successful lady students. After distributing the prizes, Lord Cross gave a short address on the work of the Institute, remarking that, as a liveryman of the Clothworkers' Company, he was glad to say that they had not been behind-hand in the cause of technical education. There was hardly a town in Yorkshire, he said, where the Clothworkers' Company had not been instrumental in establishing classes for technical instruction in connection with the textile industries. Reviewing the history of the subject, he said that, in conducting technological examinations, they were only doing what their ancestors, the masters and wardens of the guilds, had done, when, on an apprentice serving seven years to his trade, they examined his "masterpiece," to determine whether he might be admitted as a master craftsman. Though, with the age, the character of the examination had changed, in extent and object it was still the same. It was a mistake to suppose that they wanted to substitute the technical school for the workshop, for in the nature of things that was impossible, but he held that a workman who had a scientific reason for everything he did was a better workman than one who hadn't, and this reason the technical school endeavoured to supply.

After the usual votes of thanks had been proposed and responded to, the audience adjourned to the refreshment rooms to find further evidence of the liberality of the Clothworkers' Company.

## NOTES.

**Electric Light in Whitechapel.**—The electric light is penetrating into the East End. The Laing, Wharton and Down Construction Syndicate having applied to the Whitechapel Board for the granting of a provisional order, this body referred the matter to a committee, who reported in favour of the board taking the electric lighting of the district into its own hands. The clerk made a statement, from which it appeared that by improvements shortly to be made in a destructor they have erected, there would be waste heat sufficient to generate 100 horse-power of steam, which power it was proposed to apply to the working of dynamos sufficient to light a small area as an experiment. The Whitechapel Board will apply to the Board of Trade for a provisional order.

**Proposed Pacific Cable.**—The *Montreal Gazette*, of November 5th, calls attention to an error into which the *Globe* has fallen with regard to the originator of the trans-Pacific cable scheme. The *Globe* attributes the conception of the idea to Mr. Sandford Fleming, whose proposed route connected Canada with the Fiji and Sandwich Islands and Australia. Prior to this, however, it is stated that Mr. Gisborne, the Superintendent of the Dominion Government Telegraphs, had suggested a cheaper and better route *via* Japan and China. These views were published, accompanied by a chart explanatory of the various schemes, in the *Dominion Illustrated*, of 6th April, 1889. The main idea of Mr. Gisborne's route is apparently the connection with such industrially-important countries as Japan and China, instead of with unprofitable localities such as the Pacific Islands, and his scheme possesses the additional advantage of shorter sections than contained in either of the other routes advocated. As observed by the *Gazette*, priority of idea is not a matter of so much moment, excepting for the sake of such kudos as may be adjudged to the originator of the scheme. The important question is which of the proposed routes is most likely to find the greater number of supporters and the most influential partisans. There seems to be no great difficulty, other than from a financial point of view, attached to the carrying out of either of the suggested systems.

**Use of the Telegraph.**—Telegraph statistics for 1888 show that in the United Kingdom for every 100 inhabitants 140 telegrams were sent. France comes very close to this figure with 136 messages, but Germany is a long way behind with only 35. Italy follows with 20 telegrams, Austria-Hungary with 18, and Russia with only 2. "Is not the use of the telegraph," asks the *Lumière Electrique*, "a positive indication of the spread of civilisation, the progress of industries, and, to an extent, an estimate of intelligence?"

**Woodhouse and Rawson, Limited.**—On Tuesday a statutory meeting of the shareholders of this company was held at the offices in Bradford for the purpose of receiving an account of the reasons which led to the winding-up of the company, and passing a resolution of approval. Only three shareholders put in an appearance, namely, Mr. G. A. Steinthal, Colonel Harrison and Mr. J. Leach. Reporters were not admitted, and were informed that no statement of accounts would be supplied to them. A formal resolution of approval was, we understand, passed.

**Critical America.**—We notice in the New York *Electrical Engineer*, a leading article directed at our recent comments on the electro-deposition of copper. Were it not that such a thing seems impossible we should be apt to imagine that our contemporary had been inspired from this side, but we shall deal more fully with the criticisms of our American cousins in a future issue and endeavour to show that instead of being misleading, our deductions will be found correct even in trans-Atlantic eyes.

**Carbon Shields for Arc Lamps.**—If we are not very much mistaken, the Siemens's arc lamps of, say, 10 or 12 years ago, had a sheath on the lower carbon similar to that which Mr. Hazeltine employs on his upper electrode (see p. 643). Its object was, we believe, a different one; but it would be interesting to know whether any saving of carbon was effected by its use.

**Electrically-fired Mitrailleuses.**—To our readers who are connected with the War Office, the description of an electrically-fired Gatling gun will prove highly interesting, and it is more than probable that in the future there will be a great field for the employment of small electro-motors for such purposes on ship-board.

**Electric Supply Companies in Court.**—London Electric Supply Corporation *v.* Crookshank.—The plaintiffs, on Wednesday, sought to recover £167 for six months' supply of electric current to the Pall Mall Club. The plaintiffs' case was that when at the end of 1887 they had arranged to supply the club at £1 per 10-candle lamp, it was further agreed that the supply should eventually be by meter. They now claimed for six months' supply at meter value. The defendant denied having made any such agreement, and paid a sum into court on the old scale of charges.

His Lordship, in delivering judgment, said it was much to be wished that people would put their agreements into writing. The plaintiffs had no note or memorandum, and their evidence was of an exceedingly hazy character. They failed because of the careless manner in which they did business. He did not find that there was any agreement to pay by meter scale, and his judgment would be for the defendants with costs.

**Dickens and Jones *v.* Metropolitan Electric Supply Company, Limited.**—In this action, on the same day, Messrs. Dickens and Jones, of Regent Street, sought to recover damages for alleged breach of contract to supply electric light to their premises. The defendants denied that there was any written agreement, and pleaded alternatively that if they had entered into any agreement at all, it was an agreement at will only, and made subject to a proviso that the defendants were not to be liable to any damage by accidental interruptions. They pleaded that if the supply had been interrupted, it was accidentally, and by reason of the overhead wires being in an unsafe condition at a period when they could not enter upon the district in which the plaintiffs' premises were situate, for the purpose of replacing them. For the same reason they contended that they were prohibited from supplying the plaintiffs any longer, and only continued to do so by the sufferance of the Board of Trade. They stated, further, that when under the new regulations of the Board of Trade, consequent upon the new Electric Lighting Act, their supplying cable had become insufficient, they had written plaintiffs, offering to provide and fix suitable plant at their cost, which offer had been refused.

In reply, plaintiffs pleaded that, under Section 6 of the Act, defendants were permitted to continue supply until September 29th, 1890.

Evidence was given that, prior to 1888 the plaintiffs had been supplied by the Grosvenor Gallery, and subsequently by Messrs. Pritchett & Co., and that when the business was purchased by the defendant company the supply of electric energy was continued under a somewhat similar contract. It appeared, however, that though a draft agreement had been submitted to Messrs. Dickens and Jones by Messrs. Pritchett & Co., and that though the plaintiffs on taking over the business had sent defendants a printed form of agreement, neither had been signed, and Mr. Lumley Smith, for the defendant, submitted that there was no evidence of any express agreement, and that the electric energy had only been supplied and received at the respective wills of supplier and consumer, and could be terminated by either party without notice.

With this view Mr. Justice Stephen agreed. He nonsuited the plaintiffs, and granted a stay of execution for six days pending appeal.

**Forging Telegrams.**—Henry Ives, the clerk who was convicted at the last sessions of the Central Criminal Court of forging a telegram, to whose case we referred at the time, was on Wednesday last brought up for judgment. Mr. Purcell addressed the court on his behalf, and the Recorder sentenced him to nine months' imprisonment with hard labour, to date from the date of his conviction.

**Overhead Conductor Regulations.**—The memorials which have been sent to the Board of Trade by four important electrical firms are well-timed, but they might have been couched in more vigorous terms. It is almost time that the relations existing between the technical advisers to the Board and the electrical trades should be dealt with in a forcible manner.

**Fatal Electric Shocks.**—The opponents of electrical execution may perhaps change their views as to the efficacy of the method if they ponder for a while on the fatal accident which we record to-day in our "Communications from Austria-Hungary." There have been so many practically instantaneous deaths from electrical shocks accidentally contracted, that it seems too absurd to think that we shall have a repetition of the Kemmler affair as reported, although we have never been amongst those who gave credence to the harrowing details of that death-scene. The approaching end of the Japanese who now awaits the carrying out of a sentence similar to Kemmler's will probably settle once and for all the conflicting opinions which exist on the subject.

**The National Telephone Electrical Society (Midland Branch).**—The first meeting for the Session 1890-1 of this society met at Birmingham on Friday evening last (November 21st, 1890), when the President, Mr. Coleman, M.I.E.E., delivered a highly interesting address on "Telephony at the Present Time." There was a large attendance, members from outlying centres being present.

**The Royal Society.**—Last night Messrs. G. J. Burch and V. H. Velej were down for reading a paper on "The Variations of Electromotive Force of Cells consisting of Certain Metals, Platinum, and Nitric Acid."

**Electric Lighting by Gas Companies.**—It is said from March, 1889, to March, 1890, the American gas companies increased their ownership in the electric lights to the extent of almost 50 per cent.

**Electric Light Accidents in America.**—James Tucker, a foreman lineman of the East River Electric Light Company, while repairing wires in a New York street, fell upon the wires, and died shortly after.

An *employé* of the electric light company at San Francisco has received a shock which is calculated at fully 1,000 volts. The man escaped with his life, but his hands are burned to the bone.

**Lecture to Nurses.**—A lecture to nurses on medical applications of electricity (with demonstrations on living subjects) will be given on December 11th, by Mr. Newman Lawrence, at the Institute of Medical Electricity, 35, Fitzroy Square, W.

**Prospects of Electric Light in Paris.**—M. Fontaine thinks that in 1891 or 1892 the electric lighting in Paris will require for its production motive force equal, in round numbers, to 32,000 horse-power.

**Canadian Telephones.**—It is said that there are about 25,000 telephones in use in Canada, of which more than 20,000 belong to the Bell Telephone Company.

**Overhead Wires.**—The London County Council will shortly apply for leave to bring in a Bill for the regulation and control—and, if need be, removal—of overhead wires.

**The Woking Electric Supply Company.**—The directors are about to make a further issue of shares. There are to be 400 new shares of £5 each, issued for the purpose of providing a working capital. Several residents in the district have expressed a wish to become shareholders in the company, and the directors, realising the importance of obtaining local support, have decided to offer these shares in the first place in this locality only. The total capital authorised is £20,000.

**Provisional Orders.**—The London *Gazette* publishes notices of the corporate authorities of the following places who will shortly apply to the Board of Trade for provisional orders under the Electric Lighting Act:—Coventry, Southport, Ealing, Monmouth, Bolton, Kidderminster, Bromley, Croydon, Torquay, Chiswick, Stockport, Leamington, Weston-super-Mare, Cardiff, Canterbury, and Exeter. Scarborough will apply for the renewal of an order already existing, and public companies will apply for power to supply the following places: Newcastle-upon-Tyne, Weybridge, Westminster, Norwich, Exeter and St. Luke's, Chelsea and St. George's, Hanover Square.

**The Electro-Harmonic Society.**—The amateur concert (ladies' night) will take place on Monday evening, December 8th, and the programme may be seen in our supplement. Members will note with great pleasure that Mrs. Alexander Siemens has again kindly consented to sing, and a new amateur violinist in the person of Mr. Theodor Raaschon, will appear for the first time, to play one of Vieuxtemps' most celebrated and exacting compositions. With the exception of the baritone, Mr. Gordon Heller, and the youthful humorist, Mr. F. Charlton Fry, a son of that well-known elocutionist Mr. Chas. Fry, the remaining solo artistes are more or less familiar. Instrumental music will be in the ascendancy, and no doubt a very enjoyable concert will result. We may add that Major-General Webber has for the second time kindly consented to preside.

**Theatre Lighting.**—The theory of safety from fire in the electric lighting of theatres and other public places has received another check. On Saturday night, during the performance at the Comedia Theatre in Madrid, before a full house, an alarm of fire was raised, and almost immediately the theatre was in complete darkness. A panic of the worst kind appeared imminent; but, fortunately, some candles were quickly lighted, and the presence of mind of some portion of the audience sufficed to allay alarm. It was soon found that the fire was confined to part of the wings of the stage, and was of little importance, and the audience vacated the theatre quietly, without accident. The origin of the fire appears to have been the accidental connection of two imperfectly covered wires, causing them to emit sparks, which ignited some light canvas in the side scenes.

**Failure of Electric Light at Leeds.**—The *Leeds Mercury* complains about the lighting of the Town Hall. It says: "Somehow the dynamo gets lame in its supply. Two or three of the lamps catch the current and give forth a small solar blaze, but the others are as dark as the moon on the obscure side."

**The Paris-London Telephone.**—At Paris, the apparatus in connection with the Paris-London telephone will be provisionally installed at the Bourse. The telephone will be available night and day, and also on Sundays.

**London County Council.**—At the meeting of the London County Council on Tuesday last, Mr. Basset Hopkins drew attention to the fire at the Grosvenor Gallery, and asked whether the fire was caused, as he had heard, by the over-heating of an electric wire. If this gentleman, along with others, would cease to accept newspaper reports as reliable on technical subjects, there would be fewer lost sheep in this world.

**Execution by Electricity.**—The Supreme Court of the United States has approved the judgment of the Circuit Court in the case of Shibuya Judiro, a Japanese, confined in Sing Sing jail under sentence of death by electricity.

**City and South London Railway.**—A number of trains, each consisting of an electric locomotive and three carriages have been running regularly for some days on this railway, in order to educate the staff in the working of the electrical plant, the hydraulic lifts, and other matters which are peculiar to the undertaking. It is expected that the final inspection of the Board of Trade will take place within a few days, and that the line will then be open to the public. On Monday, the 24th inst., on the recommendation of the Prince of Wales, who recently inaugurated the completion of the undertaking, H.S.H. Prince Hermann of Saxe-Weimar privately visited the railway. He was accompanied by Major Cardew, representing the Board of Trade, and was met at the City Station by Mr. C. J. Mott, the chairman of the company; Mr. Greathead, the engineer; Mr. Jenkin, the general manager; and Mr. Basil Mott, resident engineer, and proceeded at once to the special train which was awaiting him at the King William Street terminus. There he was met by Mr. Wm. Mather, M.P., and Dr. Edward Hopkinson, and Mr. Grindle, the resident engineer of Messrs. Mather and Platt. The train rapidly made the journey to Stockwell, stopping at each of the immediate stations. At Stockwell, the boiler house, engine house, and carriage sheds were examined, and the electrical working was explained by Mr. Mather and Dr. E. Hopkinson. On the return journey the Prince expressed a desire to travel on the electrical locomotive, so as to more closely inspect its working. The Prince expressed himself as very much pleased and gratified with all he had seen.

**Electric Tramways Abroad.**—The recent failure of the accumulator system on the Sandhurst-Eaglehawk Electric Tramway, Australia, though it is no doubt a blow against the method of traction, does not appear to be such a complete condemnation as might appear at first sight. In the *Argus* for September 30th, it is stated that the batteries were guaranteed to give a speed of 8 miles an hour on a level road; but that, unfortunately, there were several steep gradients in the line, reaching as much as 1 foot in 20 feet, the result being that an average of about 6 miles an hour only could be attained. If the circumstances as reported are correct, it is not surprising that failure was the result; it is only a wonder that the cars were kept running for the 94 days that they did. To attempt to work such heavy gradients with the power at command was the height of folly. For the colonies, generally, there appears a splendid opening for electric traction, as the streets are wide, and, as a rule, nearly straight, and, moreover, the traffic is not congested. For some streets, however, there seems to be a great objection to the overhead system, whilst the channel system cannot be used, owing to frequent flooding; probably, however, in view of the advantages of the method of traction, overhead wires may, after all, be allowed.

**Electric Light in Barcelona.**—In a note of this subject on October 31st, we stated the *Los Anales de la Electricidad* looked unfavourably on a scheme of lighting at 10,000 volts. This voltage was a mistake, as the machines supplied by Woodhouse and Rawson United, Limited, are Ferranti machines, and only work at 2,400 volts. It is expected that the installation will be fitted up in about two months.

**Royal Naval Exhibition, 1891.**—Firms intending to exhibit objects connected with the Royal Navy or Maritime interests are reminded that all applications must be made by November 30th.

**Seeing by Electricity.**—Coining new words is seldom a successful pastime, and no matter how reasonable a suggestion may be, a host of objectors is sure to spring up who find fault, generally from "pure cussedness," if for no other reason. The use of the word "telephane" is, of course, at once objected to, but the objector in suggesting "telope" is certainly not right, as "ope" represents nothing connected with the subject. The nearest in that direction would be "teleopt," from *optikos*, i.e., pertaining to sight. "Telephane" is certainly euphonious, and its derivation from *phainein*, "to show," or *phaneros*, "visible," is etymologically correct.

**Electric Light in Birmingham.**—Two public companies, the Birmingham Electric Supply Company and the Birmingham House-to-House Electricity Company, have applied to the Board of Trade for provisional orders enabling them to supply electricity for public and private purposes in that city.

**A Storehouse of Knowledge.**—The November number of the Proceedings of the Physical Society contains a number of articles bearing on electricity, to wit:—"On a Carbon Deposit in a Blake Telephone Transmitter;" "The Villari Critical Points in Nickel and Iron;" "On the Shape of Movable Coils used in Electrical Measuring Instruments;" "Considerations on Permanent Magnetism;" "On the Results of Some Recent Magnetic Work;" "Galvanometers;" "On Huygens's Gearing in Illustration of the Induction of Electric Currents;" "On the Diurnal Variation of the Magnet at Kew;" "The Effect of Change of Temperature on the Villari Critical Point of Iron;" "Notes on Secondary Batteries."

**Tenders Wanted.**—Tenders are required for electric lighting plant and machinery for Pretoria, in the South African Republic. Particulars will be seen in our advertisement columns.

**Count Mattei Again.**—Under the heading of "People we Know," a weekly journal, which is claimed to have a certain status, holds forth as follows:—"Count Mattei, the famous Italian cancer curer, is now over two-and-eighty, but looks three decades younger, and, though he has lived for many years alone on the hills near Bologna, his manners are those of a polished man of the world. He says he owes his rugged health to the use of his famous electric globules, which he takes daily in his coffee, and which give the taker an imperceptible electric shock—the principle and secret that distinguish his medicines from homoeopathy. He tells many stories of miraculous cures he has effected by the aid of his "blue electricity," and says that he owes its discovery to a mangy dog, which every day ate at the same plant in the woods. Before that time he had cured people of nervous disorders by putting them into a completely violet room, which, he declares, is most soothing to the nerves. By trying a decoction of the plant used by the dog, he was able to cure skin diseases. His great secret lies in the fixing of electricity in these decoctions; this secret nobody knows, not even his adopted son, and when the medicines are thus far prepared by other hands, he puts the supreme and finishing touch himself." In the words of a financial contemporary, we may say, "Lord, how long?" How long will such statements be scattered broadcast to delude the ignorant, and how long will papers continue to advertise these absurdities?

After referring to the visit of Mr. Stead to Count Mattei, for the purpose of writing an article in the next issue of the *Review of Reviews*, regarding the latter's "secret electricity," the *Star* states that "the electricity is taken internally."

**New Cable Across the North Sea.**—A new cable was completed last week for the Great Northern Telegraph Company, between Newbiggin (near Newcastle) and Marstrand (Sweden). The cable was manufactured by the Telegraph Construction and Maintenance Company, and laid by that company's vessel, the *Seine*. The work seems to have been carried out with very creditable despatch. The total length of cable specified amounted, we believe, to about 550 nautical miles, and comprised the following types:—Shore end: Inner sheathing, 12 galvanised iron wires, each 0·170 inches diameter; outer sheathing, 14 galvanised iron wires, each 0·300 inches diameter. Total weight about 15 tons per N.M. Heavy intermediate: 12 galvanised iron wires, each 0·300 inches diameter. Total weight about 10·5 tons per N.M. Intermediate: 12 galvanised iron wires, each 0·200 inches diameter. Total weight about 5 tons per N.M. Deep sea, No. 1: 12 galvanised iron wires, each 0·170 inches diameter. Total weight about 3·75 tons per N.M. Deep sea, No. 2: 17 galvanised homo wires, each 0·099 inches diameter. Total weight about 2·5 tons per N.M. The core is composed of seven strands of copper, weighing 180 lbs. per N.M., and 180 lbs. of gutta-percha. The foregoing figures are necessarily only approximate, and we are unable to state the quantity of each particular type manufactured or laid.

**"A Coming Man."**—The *London Figaro* gives a short biographical sketch of Mr. Greathead, the engineer of the South London Railway, under its series of "Coming Men." Considering that Mr. Greathead is a man who "has come," it appears that the *Figaro* might have reserved its space for somebody less well-known.

**Telephonic Appointment.**—The newly-licensed Mutual Telephone Company has just concluded an arrangement with Mr. A. R. Bennett, whereby he becomes their general manager and chief engineer for three years. Mr. Bennett has retained power to practise as a consulting electrical engineer, and will have his headquarters in London. It will be remembered that Mr. Bennett resigned his post of divisional general manager in Scotland to the National Telephone Company last July in consequence of disagreements with the directors who insisted upon reverting to methods of construction which he had abandoned years before as obsolete.

**Applied Classics.**—The *Daily Telegraph* asks, Do electrical engineers, as a rule, know their Latin grammar? If not, the Postmaster-General's so-called epigram at the Criterion Restaurant on Thursday evening must have been "caviare to the general." If, however, there did lurk within their scientific brains any memory of an early and effete classical education, they must have found it somewhat difficult to reconcile Mr. Raikes's paraphrase with the original. The point of the Latin lines is that the three-fold goddess has three distinct offices with three different weapons in three divergent regions. As Proserpine she scares the shades below with her sceptre, as Luna she lights the upper air with her beams, as Diana she drives the wild beasts with her arrow. If the application must be transferred to the various uses of the electric light, it might run somewhat as follows: "The Underground she lights upon its way (or rather she ought to, if only the Metropolitan Railway Company were sufficiently civilised), or helps the high-throned 'gods' to see the play, or drives the 'Bears' on 'Change to find their prey."

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**House-to-House Electric Light Supply Company, Limited.**—At an extraordinary general meeting of the members of this company, held at the Central Electric

Lighting Station (Kensington), Richmond Road, S.W., on the 9th, it was resolved that £60,000 in 12,000 shares of £5 each, being part of the original capital, be issued as 7 per cent. cumulative preference shares, with a right of priority on any distribution of assets, and with the option of exchange of each preference for an ordinary share upon giving one month's notice. The resolution was confirmed on the 24th ult. and was registered 17th inst.

**Monte Video Telephone Company, Limited.**—The annual return of this company, made up to the 14th inst., was filed on the 17th inst. The nominal capital is £220,000 divided into 29,000 preference and 15,000 ordinary shares of £5 each. The shares taken up are 28,000 preference and 15,000 ordinary, 3,000 of each being considered as fully paid up. Upon 25,000 preference and 12,000 ordinary shares the full amount has been called, the calls paid amounting to £185,000.

**Northern Counties Electric Light and Power Company, Limited.**—The statutory return of this company, made up to the 9th inst., was filed on the 17th inst. The nominal capital is £1,000 in £1 shares, 100 of which are founders' shares; 7 founders' shares are taken up, upon which no call has been made. Office, 13, Victoria Street, S.W.

**Paddington and Bayswater Electric Light and Power Supply, Limited.**—The statutory return of this company, made up to the 9th inst., was filed on the 17th inst. The nominal capital is £1,000 in £1 shares, 100 of which are founders' shares; 7 founders' shares are taken up, but no call has been made thereon. Registered office, 13, Victoria Street, S.W.

**Electric and General Investment Company, Limited.**—The statutory return of this company, made up to the 30th September, was filed 10th ult. The nominal capital is £200,000, divided into 39,900 ordinary and 100 founders' shares of £5 each. The shares taken up are 10,000 founders' and 20,000 ordinary, and upon the former the full amount has been called, and upon the latter £1 per share has been called. The calls paid amount to £20,400, and unpaid to £100. Registered office, 1 and 2, Great Winchester Street.

**Yorkshire House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889, filed 20th inst., with the House-to-House Electric Light Supply Company, Limited, provides for the allotment to that company of 100 fully-paid founders' shares in this company, in consideration of the payment of the preliminary expenses. The first director nominated by the House-to-House Company is Mr. Robert Hammond, who is to be paid £100 per annum of the £500 per annum set aside for minimum directors' fees.

**Western House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889 (filed 20th inst.), with the House-to-House Electric Light Supply Company, Limited, provides for the allotment of 100 founders' shares to that company, in consideration of the payment of preliminary expenses. Mr. Robert Hammond is appointed a director, and is to receive £100 per annum of the £500 per annum set aside for minimum directors' fees.

**South of England House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889, and filed 20th inst., with the House-to-House Electric Light Supply Company, Limited, provides for the allotment of 100 founders' shares to that company, in consideration of the payment of the preliminary expenses of this company, and also appoints Mr. Robert Hammond a director, at a remuneration of £100 per annum out of the £500 per annum set aside for minimum directors' fees.

**Scottish House-to-House Electricity Company, Limited.**—An agreement of 24th June, filed 20th inst., with the House-to-House Electric Light Supply Company, Limited, is similar in terms to the agreements of the three preceding companies.

**Northern House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889, filed 20th inst., is similar in terms to the four preceding companies' agreements.

**Midland House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889, filed 20th inst., with the House-to-House Electric Light Supply Company, Limited, is similar in terms to that entered into by the five preceding companies.

**Manchester House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889 (filed 20th inst.), with the House-to-House Electric Light Supply Company, Limited, is similar in terms to the foregoing.

**Liverpool House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889, with the House-to-House Electric Supply Company, Limited, is similar in terms to the foregoing.

**Lancashire and Cheshire House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889 (filed 20th inst.), with the House-to-House Electric Light Supply Company, Limited, is similar in terms to the foregoing.

**Irish House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889 (filed 20th inst.), with the House-to-House Electric Light Supply Company, Limited, is similar in terms to the foregoing.

**Birmingham House-to-House Electricity Company, Limited.**—An agreement of 24th June, 1889 (filed 20th inst.), is similar in terms with the agreement entered into by the preceding companies.

## CITY NOTES, REPORTS, MEETINGS, &c.

### The Electric Construction Corporation, Limited.

THE directors' report to be submitted to the shareholders at the ordinary general meeting to be held at Worcester House, Walbrook, London, E.C., on Monday, the 8th day of December, 1890, at 12 o'clock noon, shows a profit of £52,639 3s. 2d. It further states that this may be considered as eminently satisfactory, having regard to the facts that (1) the corporation did not enter into full possession of all the properties acquired until October 31st, 1889; and (2) the corporation has not during the past year had the benefit of the increased power and economy of production to be derived from the new Bushbury Works, to which special reference is hereafter made.

From the profit of £52,639 3s. 2d., the board have written off the whole of the preliminary expenses of the formation of the corporation, amounting to £4,348 7s. 6d., and they have also carried to capital account a considerable sum resulting from licenses and re-sales of patents. No patents have been sold or licenses granted which can, in the opinion of the directors, prejudice the profit-earning power of the corporation, and possibly a certain portion of the amount so applied to capital might have been regarded as divisible profits; but, having regard to the large amount of the capital of the corporation at present represented by patent rights, the directors are satisfied that the shareholders will support the more prudent policy which has been adopted.

From the profit balance of £48,290 15s. 8d. the directors recommend:—1. That the sum of £15,000 be placed to reserve account against depreciation. 2. That a dividend of 6 per cent. be declared and paid upon the capital which has been from time to time called up, and paid in respect of the ordinary shares of the corporation, from the date of allotment on the 7th day of June, 1889, to the 30th day of September, 1890, inclusive, carrying forward the balance to the current year's account.

At an early date after acquisition of the Elwell-Parker business, the directors satisfied themselves that the existing Wolverhampton (Commercial Road) Works were inadequate to cope with the large and increasing orders for electrical goods, and particularly for those of the heavier class now in demand for central stations. A very advantageous site was secured at Bushbury, near Wolverhampton, immediately adjoining and in direct communication with the London and North Western Railway Company. Works have been there erected which, it is believed, will enable the corporation to supply electrical work of any class; but, having regard to the manner in which the business of the corporation has developed, provision has been made for still further extensions, should the necessity arise. The cost of the construction of these works with the necessary land, sidings and machinery, has, of necessity, been great; but the directors are satisfied that the capital of the corporation has been well expended.

In the prospectus of the corporation, it was stated that "as the business and profits of the corporation increase the directors will

from time to time propose the issue of additional capital, but care will be taken that the holders of the original capital shall be entitled to a preference or priority of allotment in subsequent issues." To secure the full advantage and profits of increasing business, it is desirable that a considerable addition should be made to the resources of the corporation. In the opinion of the directors a debenture issue would be more economical and advantageous to the present shareholders than an increase of capital either by ordinary or preference shares. Subject to any expression of opinion on the part of the shareholders at the general meeting, the directors therefore propose to make a sufficient debenture issue. Care will be taken that shareholders desiring to subscribe to these debentures shall have the opportunity of doing so.

In accordance with the articles of association, four of the directors, viz., Sir Daniel Cooper, with Messrs. Balfour, Courtenay and Dibley, retire from the board, all of whom are eligible, and offer themselves for re-election. The directors regret that the pressure of his professional engagements has compelled Sir Douglas Fox to resign his seat at the board. Sir Henry C. Mance, C.I.E., has consented to give the corporation the benefit of his great experience and scientific knowledge, as chairman of the board.

Messrs. Broads, Paterson & Co., the present auditors of the corporation, retire and offer themselves for re-election.

### Swan United Electric Light Company, Limited.

AN ordinary general meeting of the above company was held on Tuesday last at the Cannon Street Hotel, when the eighth annual report, which appeared in our last issue, was presented, and a balance of 10 per cent. for the year was declared.

The Chairman (Mr. J. S. Forbes), in the course of his remarks, said: The share capital of the company amounted to £375,000. Of this, £3,531 had been paid by people who had omitted to pay up their calls, and was consequently forfeited to the company. The cost of patent rights, &c., represented by shares in the Edison and Swan United Electric Light Company, was £208,478; shares in La Compagnie Générale des Lampes Incandescentes amounted to £30,489, and over and above those two solid assets there were patents held by the company for Germany, and other sources of income which were open to them as possessors of patent rights in England and abroad—outside of Europe. The absorption of the British business of the company by the Edison and Swan Company had been a very happy investment for them, as the bulk of the dividend which it was proposed to divide that day had come to them in respect of shares held in the Edison and Swan Company. Referring to the French Company, they had been in litigation with a powerful body of people in France—and France meant Russia, Austria, and other countries as well—for the Edison and Swan Company were doing in France what they had been doing in London, litigating the patents. They had thought it wise to avoid litigation among themselves and come to terms. A company was formed, a certain amount of money was subscribed by the two companies, and each was credited with a further sum in the nature of a goodwill. Out of Europe they had all the world—with some exceptions—which they could supply with lamps if they could find the customers. Referring to profit and loss, among other items was £26,733 due from sundry debtors, a large sum of money, but about £23,000 of it was dividend payable by the Edison Company to themselves. The older shareholders would remember that for some years no dividend had been paid, and, what was worse, the balance at the end of the year had been against the undertaking: they had determined as a matter of prudence to write down out of the profits of the following years all losses realised in the earlier years of the company. Their first balance to the good had been in 1887, in the following year they had had a further credit balance, but the proprietors had concurred with the directors in recommending that both amounts should be held in hand, and it was in 1889 that for the first time in the history of the company a dividend was distributed. The sums thus saved figured now in the balance sheet. The total outlay upon patent rights amounted now to £330,837 2s. 5d. They had been writing down their stock and plant very liberally for a number of years. They had an investment in the Prussian Consols, which the German Government had required them to deposit as a sort of caution money, and £29,004 19s. 6d. invested in the 2½ per cents. Cash on deposit and in hand amounted to £10,669 16s. Referring again to the item of stock, they had thought it prudent to write down stock approximately to the manufacturing price, because something might arise which would prevent the sale of a large stock of lamps at a much higher one, and lamps were put down at 10d. each which if sold for even so low a price as 1s. 6d. would leave a very large profit. Office expenses, &c., amounted to £3,513, and wages and expenses at factory to £5,000. On the other side of the account they would see among other figures the dividend on the shares in the Edison and Swan, £30,665 13s. 8d., which was quite 8 per cent. on the money invested with them. Those who had taken sufficient interest in the company, attended its meetings, and read its reports, knew that its future was likely to be fairly prosperous. They had protection for a certain number of years, but their policy was not founded upon protection. They hoped at the end of the protected period to have such a capacity, and such a clientèle that nobody should be able to work against them; but so long as protection lasted the dividend from the Edison and Swan Company might be looked for as a considerable one. The French

company had only just started, but already they had a very fine factory, though they had not succeeded so well as the English company in producing an efficient and economical lamp. It took a long time to get into the best groove, but they had all the advantage of the experience gained by the English company. Another difficulty of the French company was that they were still in litigation, and that a number of people took advantage of the fact to infringe their patents. Until the litigation was settled, too, they did not know the value of their business there. In Germany they were engaged in litigation with the Edison Company, and until the decision of the Supreme Court at Leipzig, to which they had appealed, was given, they would not know whether they had a right to make and sell their lamps in that country or not. The Chairman concluded by moving the adoption of the report, which was carried.

A few remarks by Mr. F. J. Mills were replied to by the Chairman, and the two retiring directors (Mr. F. R. Leyland and Mr. W. C. Quilter) were re-elected. The usual vote of thanks concluded the meeting.

### The Montevidean and Brazilian Telegraph Company, Limited.

AN extraordinary general meeting of this company was held at Langthorn House, on Tuesday, to receive special resolutions as to the winding up of the companies, and to consider an agreement made with the Western and Brazilian Telegraph Company for taking over the whole undertaking. The solicitor, having read the agreement,

The Chairman, in explaining the state of affairs, dwelt with satisfaction on the good bargain which he considered had been made. If anyone was inclined to cavil at the results of the working of the company, he would remind them that the present directors were not responsible, as when they came into office 15 or 16 years ago the affairs were in a very bad way. The first duty was to rescue the company from bankruptcy, and the secretary and himself had to assist the company by advancing a considerable sum of money to tide over difficulties. They had never been able to develop the resources of the company, because agreements with the Platino Company and the Western Brazilian Company bound them hand and foot. The speaker then referred to the agreement of 1885, which was drawn out, but was not finally accepted for some reason or other by the Western Company. Had this taken place at that time the property would have been secured on much better terms. On account of their own shares being now more valuable, a highly favourable arrangement had been made.

After further remarks the following resolutions were adopted:—

1. That the company be wound up voluntarily under the provisions of the Companies' Acts.
2. That George Fraser, F.C.A., be and he is hereby appointed the liquidator to conduct such winding-up.
3. That the agreement submitted to this meeting, dated 3rd November, 1890, and expressed to be made between this company of the one part, and the Western and Brazilian Telegraph Company, Limited, of the other part (being an agreement for the sale and transfer to the Western Company of the whole of this company's undertaking) be and the same is hereby approved. And that the liquidator be, and he is hereby authorised, in pursuance of Section 161 of the Companies' Act, 1862, and of all other powers enabling him in that behalf to carry said agreement into effect with such modifications (if any) as he may think expedient.
4. That the liquidator be and he is hereby authorised to receive, and when received to distribute amongst the holders of preferred shares in this company, the rent accruing to this company from the Western and Brazilian Telegraph Company, Limited, for the year ending 31st December, 1890.

A meeting to confirm the foregoing resolutions will be held in a fortnight's time.

### Blackpool Electric Tramway Company, Limited.

#### ANNUAL MEETING OF SHAREHOLDERS.

THE sixth ordinary general meeting of the members of the Blackpool Electric Tramway Company, Limited, was held at the Victoria Schools, Tyldesley Road, Blackpool, last Saturday afternoon. Mr. Alderman Richard Horsfall, J.P., C.E., F.S.I. (Halifax), chairman of directors, presided, and the following directors were present:—The Mayor of Blackpool (Mr. Alderman J. Bickerstaffe); Mr. T. H. Morris, J.P. (the Lodge, near Halifax), Vice-Chairman; Mr. J. Broadbent (Manager), Blackpool; Mr. G. H. Smith, Park House, Halifax; Mr. John Oddie, Halifax; Mr. Theodore Ormerod, Elm Royd, Brighouse, directors.

After the report had been read (an abstract of which appeared in the REVIEW last week),

The Chairman said it was his pleasure to meet them again as chairman of the Blackpool Electric Tramway Company, and to congratulate them, he thought, upon their balance-sheet. He did not know that he could say anything to them that day, excepting perhaps that they were working satisfactorily, all the machinery was in good working order, their furnaces were good, and that the directors felt that they came before the shareholders with a thoroughly sound and honest balance-sheet. (Hear, hear.) He had great pleasure in proposing the adoption of the report and balance-sheet as presented.

Mr. MORRIS (Vice-Chairman), in seconding the resolution, concurred in the remarks of the chairman. All their plant and property was in first-class order, while the prospects of the company, so far as they were able to judge, were never more satisfactory than at the present time. The dividend had been honestly and satisfactorily earned, and the amount put away for depreciation was felt to be needed for contingencies that might arise in the future.

The resolution was carried unanimously.

ELECTION OF DIRECTORS.—SOMETHING LESS THAN A COMPLIMENT.—AN OUTSPOKEN SHAREHOLDER.

Mr. Barcroft moved that the retiring directors, Messrs. Ormerod, Shaw and Smith be re-elected.

Mr. Hoyle: Does Mr. Holroyd Smith (patentee) ever attend?

Mr. G. H. Smith: I am his brother; he is not on the directorate.

Mr. Hoyle: Oh, that alters the case. I was going to ask him a question or two, for a more one-sided bargain, from first to last, I never came across than the one made by this company with the Blackpool Corporation. It is so bad in fact, that I consider it a positive disgrace, and I am ashamed to tell anybody about it. (Laughter.) It was the most one-sided business he had known "since he were created." (Loud laughter.) Was there any need to re-elect the three retiring directors? He had been at meetings where he had heard of the directors of that company say that five directors were ample. He believed they could be too many.

Acting on a suggestion here, the attendances of the directors were read.

The Chairman said the meetings varied according to the season. He came down frequently, and if he thought it necessary to hold a meeting, one was called. There were no fixed dates for meetings. In answer to a question, the Chairman said they had two resident directors. Formerly they had three, but Dr. Kingsbury had sold out his shares.

Mr. Hoyle said he might say that he had so much confidence in the manager, that he believed if the directors never came but once a year that they would not be any worse off. (Laughter.) It was more a matter of form having them as directors than anything else, in his opinion. (Renewed laughter.) Only they were a large number; whether they were all electricians or not he could not tell. No doubt all the shareholders would have been charged with something of the sort had there been no dividend for them. (Laughter.) He, however, had no objection to seconding the re-election of the three retiring directors. (Hear, hear.) Was it necessary to take the three together?

The Chairman: You require to give seven days' notice before proposing a new director, according to the rules.

Mr. Hoyle: Are there articles of association?

The Chairman: Yes.

Mr. Hoyle: I would be glad to have one and pay for it.

It was agreed to supply them to all shareholders at 1s. each copy.

Mr. Hoyle: I understand that at the end of seven years this concern can be taken from us by the corporation?

The Chairman: The corporation can give us notice during the last term of the first seven years. On the other hand, if they do not take that course, we shall have to give them notice that we wish to continue in possession. Then the same routine is gone through at the end of 14 years, and then if we keep it for 21 years, we shall reach the expiration of the agreement. This fact accounts for the large sum put to depreciation—we are compelled to provide for the worst contingency.

Mr. Hoyle: If it is a good thing they can take it?

The Chairman: Yes.

Mr. Hoyle: Then you may rely upon it they will take it. Blackpool people know a good thing when they see it, you may depend on that, and anything they can lay their hands on they will not let go past them. I have not much confidence in Blackpool people, I can tell you. I know them. (Laughter.)

The Chairman: If they take it they will have to pay for it.

Mr. Commissioner Buckley: Those who have got shares at a premium are likely to lose money by such an arrangement.

The Chairman: Well, I suppose they bought the shares for the dividends, and 7½ per cent. capitalised will make up the difference. Any shareholder who wishes to see the agreement between this company and the Corporation can do so only with the consent of the directors. This precautionary measure was necessary in the interests of the company.

The resolution was carried.

#### ELECTION OF AUDITORS.

Messrs. J. D. Taylor & Co., of Halifax, were reappointed auditors to the company, on the motion of Mr. Hoyle, seconded by Mr. Barcroft.

After further remarks and a vote of thanks to the directors, the meeting terminated.

#### TRAFFIC RECEIPTS.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending November 21st, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £4,421.

The Brazilian Submarine Telegraph Company, Limited. The traffic receipts for the week ending November 21st were £6,637.

## ITALIAN TELEGRAPH STATISTICS.

The following statistics are compiled from a recent official return regarding the position of telegraphy in Italy from July, 1888, to June, 1889:—

<i>Telegraph Lines.</i>		
Length in miles	...	21,647
Length exclusively for railway service	...	1,424
Mileage of wires	...	61,455
Mileage of wires for railway use	...	19,279

<i>Telegraph Offices.</i>		
State offices	...	2,437
Railway and private offices	...	1,369
Various	...	40

<i>Telegraph Apparatus.</i>		
Morse type	...	3,789
Hughes "	...	101
Various "	...	63

<i>Personnel.</i>		
Central office	...	213
Other offices	...	7,036

<i>Home Telegrams.</i>		
Subject to taxes	...	6,364,212
Despatched by the railways	...	713,797
Exempt from taxes	...	583,246

<i>International Telegrams.</i>		
Sent abroad	...	646,980
Received from abroad	...	773,829
" in transit	...	131,482
Service messages	...	216,860

<i>Receipts.</i>		
Home messages	...	£409,374
Foreign "	...	147,328
Various "	...	32,987

<i>Expenses.</i>		
Extraordinary: new offices, &c.	...	£23,979
Ordinary staff expenses	...	345,682
Maintenance, &c....	...	166,133

DINNER OF THE INSTITUTION OF  
ELECTRICAL ENGINEERS.

The second annual dinner of the Institution of Electrical Engineers was held last Thursday evening at the Criterion Restaurant, Dr. John Hopkinson, F.R.S., President, in the chair. About 200 gentlemen sat down to table, and among them were:—The Right Hon. H. C. Raikes, M.P. (Postmaster-General); Mr. Latimer Clark, F.R.S. (past president); Sir E. E. Webster, Q.C., M.P. (Attorney-General); Prof. G. Carey Foster, F.R.S. (past president); Mr. G. Berkley (vice-president Institution of Civil Engineers); Prof. W. Grylls Adams, F.R.S. (past president); Mr. W. H. M. Christie, F.R.S. (Astronomer-Royal); Mr. Edward Graves (past president); Prof. J. J. Thomson, F.R.S.; Sir Douglas Galton, K.C.B., F.R.S., D.C.L.; Major F. A. Marindin, R.E. (Inspector of Railways, Board of Trade); Major P. Cardew, R.E.; Sir Albert Cappel, K.C.I.E.; Sir Henry Mance, C.I.E.; Mr. Gisbert Kapp; Sir George Gabriel Stokes, M.P. (President Royal Society); Mr. W. H. Preece, F.R.S. (past president); Mr. J. Tomlinson, jun. (President Institution of Mechanical Engineers); Major-General Webber, C.B. (past president); Sir R. Rawlinson, K.C.B. (Vice-President Institution of Civil Engineers); Mr. C. E. Spagnoletti (past president); Prof. Dr. Coleman Sellars (member of the International Niagara Commission); Prof. D. E. Hughes, F.R.S. (past president); Sir Stevenson Arthur Blackwood, K.C.B. (Secretary General Post Office); Sir David Salomons (member of council); Captain W. J. L. Wharton, R.N., F.R.S. (hydrographer to the Admiralty); Sir James N. Douglass, F.R.S. (member of council); Sir James Anderson (member of council); Sir H. Trueman Wood (Secretary Society of Arts); Prof. S. P. Thompson, B.A., D.Sc. (member of council); Colonel B. Raynsford Jackson (member of council); Captain Stiffe; Mr. R. E. Crompton (vice-president); Herr Fritsche; Dr. Fleming; Mr. J. W. Swan; Mr. Bidwell, F.R.S.; Staff-Commander E. W. Creak, R.N.; Mr. W. Crookes (vice-president); Mr. J. C. Lamb, C.M.G.; Major-General Stotherd, C.B., R.E.; Prof. George Forbes, F.R.S.; Prof. W. E. Ayton, F.R.S. (vice-president); Prof. W. C. Unwin, F.R.S.; Mr. Gordon; Mr. Alexander Siemens (vice-president); Mr. F. H. Webb (secretary); and Mr. F. H. Webb, jun.

The PRESIDENT, in proposing the "Army and Navy," said he could have wished that this toast had been consigned to abler hands, but the committee who had arranged the toasts had insisted

that it was the duty of the President to propose the major portion of them, and he had to give way. If there was any one profession to which electrical engineers were indebted more than to any other it was the profession of arms. The telegraph was the nervous system of the army in the field, the application of electricity to explosions and to submarine minings was a necessity, and the largest arc lights, as they knew, were those which were employed observing the approach of hostile torpedoes; while, further, if the nation were not ready to repel aggression by force of arms, the enormous system of submarine telegraphs could hardly exist. He coupled with the toast the name of General Stotherd, who, as they knew, paid considerable attention to field telegraphs, and who was also head of the ordnance survey. With the toast of the navy he coupled the name of his friend, Captain Wharton, who was best known in connection with the more peaceful functions of the navy.

General STOTHERD spoke of the enormous sums of money spent in order to bring the army and navy to that state of efficiency which has been necessary of late years. When he was at Chatham, nearly 20 years ago, he had the pleasure of organising the field telegraphs, also the system of submarine mines, which had since been adopted. The gallant gentleman referred to the extensive use of the telegraph in the last Russian campaign, and averred that in the wars in the Soudan and South Africa the extensive operations could not have been carried out without it. While speaking of the electric telegraph, he drew attention to the extensive reserve in connection with field telegraphy in the Post Office. By means of that reserve they had been able recently to enter upon—and without difficulty to carry on—operations simultaneously in the Soudan and in South Africa. With regard to submarine mines, they had not yet, he was glad to say, had any opportunity of trying what they could do in war, and, indeed, he sincerely hoped they would never have to use them. Many people were averse to them because they thought merchant vessels would be prevented coming into port; but he entirely disagreed with them. The system was so arranged that there would be no difficulty whatever.

Mr. RAIKES, in returning thanks, said: Mr. President and Gentlemen, it is, I am aware, no small honour to return thanks for the toast of Her Majesty's Ministers in such a company and on such an occasion. And yet I feel some little diffidence in addressing myself to the task when I remember that it has been previously performed by no less a person than the head of the present Government, the Marquis of Salisbury, and he is not only the head of the Government, but he is, what I cannot pretend to be, a somewhat expert electrician. I have also near me another friend of mine, who likewise belongs to her Majesty's Government, the Attorney-General, who is known to many gentlemen here not less as an electrical expert than as a profound lawyer; and on one very important occasion, when I had recourse to his advice, I found that, in my opinion, his electricity was as good as his law. (Laughter.) At all events, his electrical skill enabled us to steer out of a difficulty which otherwise might have required us to apply to his law. (Laughter.) It is no doubt a fact that the department which I am called on to preside over has closer relations with electrical engineering than perhaps any other of the great departments of the State. It is not necessary that I should refer in detail to the enormous amount of telegraphic business which has grown up in the 19 years during which the department of the Post Office has been charged with its administration in this country. But it is probably interesting to know that in that time the number of telegrams has grown from 10,000,000 in 1871 to 62,500,000 in 1889 that is to say, it has sextupled in the course of those 18 years. You will easily understand how important it is for our department to be *au courant* with all the latest developments of electrical science and the wonders of electrical skill. It is not without feelings of pride that I recall the fact that the Post Office has given to this institution three of its presidents—Mr. Scudamore, Mr. Preece, and Mr. Graves—for all of them occupied the chair which you, Mr. President, now fill; and I am happy to think that they have been able to render great service to the science of electricity at the same time that they have not thereby been induced in the smallest degree to neglect their public duty to the department which they so efficiently served. But it is not the Post Office alone of Government departments which has relations with electrical engineering. Second to the Post Office, if indeed second, is the Board of Trade in relation to your science. The Board of Trade has special charge of lighthouses, and the Board of Trade has had the opportunity of testing and of specially utilising more than one of the considerable discoveries of your president in that branch of electric science. We can only regret that in the neighbouring country of Spain, on whose shores that terrible catastrophe happened the other day, there is not, as far as I am aware, either a Board of Trade or an Institution of Electrical Engineers. If they had the advantages which we possess, we might hope and believe that the lights at Cape Villano might have been in such a state as to prevent the loss of that good ship and of those brave lives that went down into the deep. The Board of Trade is not only interested in lighthouses, but also in the great question of electric lighting. I know that a great many gentlemen, and perhaps a majority of those present, are of opinion that electric lighting has been unduly arrested by the jealousy of Parliament, or of departments of the Government. I understand that feeling, but I do not share it. When you have a young science, it is desirable to give that science time to feel its feet, and in some way appreciate what it can do before you rush headlong into employing it. I cannot but think that Parliament has been wise in holding

its hand for some years before taking any decisive steps for licensing and extending the use of the electric light, because it has no doubt given time for experiments to greatly improve the science, and to secure for the public, now that they are beginning to make use of it, a very much better article in the way of electric light than they would have done had they rushed blindly into it eight or ten years ago. The Board of Trade has another connection with electrical engineering—with respect to electricity as a motive force. The recent opening of the new subterranean railway in South London has given us all an opportunity of testing, by actual experience, how this most interesting experiment will work, and it will be the special duty of the Board of Trade to keep its eyes open, to study the working of the new system, and report upon it in an independent way, which will enable the public generally to judge for themselves how far that experiment may be imitated elsewhere. Then the Admiralty has its relations with electrical engineering, because day by day it is becoming more and more necessary to have recourse to electricity in handling those great monsters of the deep, which are the fighting ships of our day, and are so ponderous and unwieldy, that ordinary skill might be powerless to handle them. The War Office, too, as you know, is also dependent on electrical engineering, for no man nowadays could take the field for a campaign unless he had obtained the best means for the supply of information, both from the front to headquarters and from headquarters to the front. Therefore you see all those departments of the State are separately very much beholden to the electrical engineers. It is on behalf of them all that I address you this evening and tender to you the grateful thanks of her Majesty's Ministers for the great services you have rendered to them. It is almost impossible, in dealing with the operations of a body like this, to over-estimate the enormous changes which through your instrumentality are affecting our daily life. I am not going to say, as I believe some enthusiasts say, that you have actually annihilated time and space, but you have so far modified time and space that it is impossible for those who live in this day to attach to those words anything like the sense in which they were used in the preceding generation. You are perpetually finding out new fields. It is not merely that you have covered all these grounds, but you are making for yourselves a great field in manufactures; and even in the healing art electricity is coming to play a very important part. Not only may a man be taken to his business in the morning by electricity, not only may he see his manufactory conducted by electricity, but he may have the advantage of having his tooth taken out by electricity if he has any weakness of that kind. It is impossible to forecast the enormous future before this particular branch of science. You seem to have taken to yourselves the attributes of the whole of that Pantheon, the whole of those influences which in ancient days were supposed to dominate our sublunary life. But if I had to single out among those mythological deities any one which might seem more appropriately to be the patron or patroness of your science, I would say that you seem to me to have borrowed in a special degree the attributes of that goddess who, we remember—probably those of us who still retain the rudimentary features of our school training—adopted a threefold name and a threefold aspect. If you will permit me, I will conclude with those two lines with which our Latin grammar has made us familiar:—

"Terret, lustrat, agit Proserpina, Luna, Diana,  
Ima, suprema, feras, sceptrum, fulgore, sagittâ."

As I was coming down here I thought I might perhaps venture to string together this little paraphrase of those lines:—

"Our threefold goddess, with her magic spells,  
By turns alarms, enlightens, and impels,  
While hangs the pale exchange upon her strings,  
Her lamp cheers cities, and her touch gives wings."

Mr. LATIMER CLARK, Past-President, in proposing "The Learned Societies," said it was unnecessary for him, in a meeting such as this, to give any commendation or recommendation to that toast. They knew perfectly well what the learned societies had done for them and for science; they knew they had given lustre to the times in which they lived. They had to a large extent, perhaps, created benefits to the electrical engineers greater than to any other body of men. They—the electrical engineers—had received from those societies, to a very large extent, the laws which enabled them to know the behaviour of that singular agent, or fluid, or force with which they had to deal. But the learned societies had a yet higher claim upon their respect and admiration. The learned societies of this and other countries had been able to pursue not only the love of science and the desire to gain knowledge, they had also been able to attain, or to endeavour to attain, to absolute truth; and, so far as he knew, no other human agency sought that truth from such pure motives as the learned societies. Whatever might be the consequence of those researches, they sought truth and truth only. He therefore proposed this toast, coupled with the name of the President of the Royal Society, Sir George Stokes.

Sir GEORGE STOKES, in responding, said the toast of "The Learned Societies" was a very wide subject, if they took in all the institutions which deserved that name. From the nature of those institutions, and from the speech of the gentleman who proposed that toast, he supposed it was not meant to include in that term literary and philological societies, but to confine themselves more especially to scientific societies; though here the field was somewhat limited, because there was another toast which would be proposed in due time—the kindred societies—societies kindred

to the Electrical Engineers. It was quite true that there were societies who had claims to abstract discovery of scientific truth, apart from its applications. These discoveries, he had no doubt, formed the groundwork of subsequent applications, and there were many such societies, due to particular branches of science, with which electrical engineering was brought more especially into contact. It was brought into contact even with abstract mathematics. It was brought into contact, again, with chemistry, that strange agent which they had to deal with and turn so much to practical account, for electricity, as they knew, was intimately bound up with chemistry. Circumstances at the present led him to look more to the future than to the past. No doubt his name had been connected with this toast in consequence of the honourable office which for the present he was filling; but his tenure of that office was now drawing to a close, and in a few days he would cease to hold it. Perhaps he ought not to name his successor, because that was determined by the votes of the fellows, and those votes were given by ballot; yet he thought it was what he could call an open secret that in all human probability his successor would be one who, though somewhat his junior in age, he could look up to as his master in science, and more especially in electricity. He was one well acquainted with them, and he had already filled the position which his friend on the right occupied at that very moment. With that he would say no more.

Mr. W. H. PREECE proposed "The Kindred Societies," and said that there was every reason to hope that the next President of the Royal Society would be Sir William Thomson.

Mr. GEORGE BERKLEY, Vice-President of the Institution of Civil Engineers, responded, and referred to the cordial intercourse which existed between American Engineers and those of this country, pointing out that after a visit to the United States one came back with the feeling that this country was somewhat behind in adopting the advantages which electricity conferred.

The PRESIDENT proposed "Our Guests." Referring to the Attorney-General, he said that there was no one by whom it was more pleasant to be examined in cross-examination; but, whether as friend or as foe, in time one's admiration for his strength and judgment was almost overshadowed by a respect for his honesty of purpose and firmness. They would also find that the honourable and learned gentleman knew a great deal about electricity, and that he had consented to join the institution. Their other guest was Dr. Coleman Sellers, member of the International Niagara Commission, who having attained to the highest eminence in other branches of science, was considering the problem of utilising to a useful purpose part of the vast energy which was going to waste in the falls of Niagara.

The ATTORNEY-GENERAL on rising was received with loud applause. He said: Mr. Chairman and Gentlemen,—I feel it a great privilege to have been selected as one of two who are to respond on behalf of the gentlemen who have been invited here to-night, and I honestly wish that by some process of induction or otherwise I could worthily represent the feelings of thankfulness which, I am sure, are in the breasts, or some other part, of the persons of the gentlemen who have enjoyed the excellent dinner that has been set before them to-night. I fear, though, that had they known that I was to be selected as a speaker on their behalf they would almost have resented it; for they have heard, on no less an authority than the Postmaster-General, that my law is as bad as my electricity. I confess I shall go out of this room to-night a sadder and, I trust, a wiser man, determined by some process or other to endeavour to imbibe, if not a little more law here, a little more electricity, which may conduce to a higher standard, up to which I may direct my law. My excellent friend Dr. Hopkinson has spoken in kindly terms that there are many in this room whom I have met in combat. I have always liked to see them on my side, and when they were opposed I regarded it as a temporary misfortune as far as I was concerned. I confess I never knew before that I was going to join the society because I was an electrician. I was asked by a very distinguished electrician, no less a person than my friend Sir David Salomons, whether I would consent to become a member. I said, "I thought you only admitted great electricians." "Oh," he said, "we take duffers as well." (Laughter and applause.) On these terms I felt that there were some possibilities of my being not blackballed but elected. It is not for that reason only that I have a very great desire to improve my knowledge of electricity, and I think that if I were to dine here more frequently, to sit between Mr. Latimer Clark and Mr. Preece, that some secondary currents might possibly find their way into my miserably insulated body—perhaps I ought to say, my perfectly insulated body, so far as electrical ideas are concerned. Years ago I studied secondary batteries, or tried to, and I think they represent my constitution. My excellent friend Mr. Crompton told me that I was no good; I charged very well, but discharged much too rapidly. (Laughter and applause.) I am at the present time in a state of despondency, because not very long ago, while considering some of these abstract problems, I met Prof. Forbes, and I explained to him my condition. After looking at me very carefully he said, "You are wound the wrong way, you want re-winding." (Laughter and applause.) I am possessed by the hope that some subtle agency will possibly do something for me. I have thought that I might venture to ask for admission within these sacred portals. I hope that many of the guests on whose behalf I have spoken will follow my example. I can assure you that it has given us much pleasure to be here, and we shall be only too glad to be your guests on any future occasion.

Dr. SELLERS (America), in his speech, referred at considerable length to the project of utilising the waters of Niagara.

Mr. RAIKES, in proposing "The Institution of Electrical Engineers," pointed out that the Institution of Electrical Engineers then called the "Society of Telegraph Engineers," was founded in 1871. The total number of members of all classes in 1872 was 268. In the present year it was 1,738, an increase of 1,470. In 1872 there were only two "students" in the list, whereas now there were 102. The students generally were young men employed by companies and firms of one kind or other. They benefited by hearing the papers read at the ordinary meetings of the institution, but they had also a special organisation, and held meetings of their own. Sir David Salomons, a member of the council of the institution, had recently founded an exhibition for the benefit of the students. The exhibition was awarded, after a suitable examination conducted by the staff of one of the technical colleges. The institution had an invested fund of £2,300, and might now be considered as occupying an assured position. Referring to matters in which electrical engineering concerned our daily life, he recalled the system of block signals on railways, and the great advantage of synchronising time in the most distant parts of the kingdom, and thus securing one cardinal time. This was of enormous benefit in regulating all sorts of matters connected with daily life and ordinary commerce. It was to the electrical engineers that they owed their system of 120,000 miles of submarine cables, and within the limits of these islands 2,000,000 miles of telegraphic system. That did not, he believed, include the telephonic systems, but on this burning question he would say as little as he could; with the expiry of the telephone patents in the course of the next year or two, a fresh field would be opened for the inventive genius of electrical engineers.

The PRESIDENT briefly acknowledged the toast, after which the company separated.

## CORRESPONDENCE.

### The Electro-Deposition of Copper.

I would have been content to leave this matter to the judgment of your readers, having clearly set out eight points in which your objections to the process were in my opinion unfounded, and which eight points remain unanswered.

You, however, imply by your note in last week's issue, that my meaning was not clear to you, and I will therefore restate with greater fulness the points which dispose of your previous criticisms upon the process.

1. Your calculation of the current necessary was "practically ridiculous," because

(a.) You assumed 60 hours per week instead of the usual 156.

(b.) You assumed that the whole of the depositing goes on in one tank, which is, of course, out of the question.

By these two assumptions you arrived at the enormous figure of 287,620 ampères, a current which, if correct, would certainly be a serious objection in practical work.

The correct figure is somewhat less than 3,000 ampères, as appears clearly in Dr. Hopkinson's report from which you have quoted.

The following extract from *Nature* (January 26th, 1888, p. 303), endorsed by Dr. Gore in his well known book (p. 7), is further confirmation of my contention. "Messrs. Bolton at Widnes, and Messrs. Vivian, as well as Messrs. Lambert at Swansea, are each depositing 40 to 50 tons per week by currents [of] from 5,000 to 10,000 ampères."

2. Your calculation of the resistance of "the bath," founded upon the necessity of a current more than 90 times as great as that actually necessary, is consequently incorrect in the same degree; and the fact of your making this calculation shows distinctly that you contemplated the work being done entirely in one bath or on one circuit, which, I repeat, is practically out of the question.

3. The necessity for this enormous "bath" conceived by you therefore disappears in reality, and I may add that the size of the tanks in the Elmore process has never presented the slightest difficulty.

None of the "eminent scientists and authorities," quoted by you, have written a word that will support your contention that "20 tons per week would involve the use of enormous tanks worked under conditions

that would be impossible except by a heavy outlay for plant and tank space.

4. As a proof of your wisdom in accepting my view as to the practical range of current-density, I would again refer you to Dr. Gore (p. 208), where he says, "the range of variation in these cases is from 0.82 to 10 ampères" [per square foot].

You add that you fail to see the force of my contention. It is this, that the weight of metal that can be deposited in a given time with a given tank plant is, *ceteris paribus*, proportional to the current density which is feasible, and therefore the higher current density in the Elmore process effects a corresponding economy in tank plant.

5. You have not been able to deny the correctness of my criticism.

6. Again, you do not deny my statement but rely upon a quotation from Mons. Fontaine's book, which applies to the state of the industry more than five years ago. Your quotation is now entirely misleading, for, as I stated, the cost of refining a ton of copper cannot be £12, inasmuch as the market price does not exceed £8.

7. I am glad that you disclaim any intention to reflect upon the quality of the articles produced by the Elmore process.

The belief expressed by me, as to the profit to be made in the manufacture of wire by this process, is founded upon facts which have already appeared in an article in your journal, and upon opinions expressed by manufacturers of many years' experience.

8. In confirmation of my statement that competent authorities had verified the correctness of the statements, which have been made with regard to the cost and quality of the articles manufactured, I enclose you a copy of the report, by publishing which you will oblige me.

I may mention that Messrs. Vigreux and Bourdon are professors at the Central School of Arts and Manufactures of France, and were respectively head and assistant engineers in the Mechanical and Electrical Section of the Paris Exhibition of 1889. Mons. Secretan's practical knowledge of the subject is beyond dispute.

With regard to your demand for a detailed statement of the cost of manufacture, the Elmore Company have, in the exercise of their undoubted right as manufacturers, objected to these figures being given by me.

W. Stepney Rawson.

November 19th, 1890.

### Report of Mons. Eugene Secretan.

[TRANSLATION.]

17, Boulevard Beausejour,  
Paris, October 15th, 1890.

To the President and Members of the Board of  
The French Elmore Company, London.

Gentlemen,—In accordance with what was agreed at the last board meeting, Messrs. Vigreux and Bourdon, members of the committee, and I, went to the factory at Leeds to inspect it, and to make ourselves definitely acquainted with the value of the Elmore process, and of the cost to manufacture by it.

My colleagues and I have been able to satisfy ourselves that the figures that were given to us were perfectly exact, and the experiments we made upon articles manufactured before us demonstrated to us in the most absolute manner the high qualities of the articles obtained by this process.

\* The statement which accompanies this is prepared upon the supposition that at least 900 tons per month are made—an amount which it is easy to reach in a very short time.

The expenses set out in this statement are taken at the maximum, and cannot be exceeded, but, on the contrary, can be reduced when a definite project is prepared.

The receipts have been taken certainly at the minimum, as the prices calculated are based only upon very low figures, and below those which are currently quoted.

My colleagues and myself, as well as the very able technicians men who accompanied us, have no doubt that the Elmore process

\* The statement referred to is a long and detailed technical report on the cost of production and prices to be realised.

will permit of the economic manufacture of articles which are sold at very high prices, and this would form a large revenue not included in our calculations.

Now, the above being well established, it is necessary [to] take immediate steps to commence work, and I therefore beg of you, Gentlemen, to take into consideration at the very first meeting of your board the following proposal, and to adopt it in principle.

However, you may find it is more prudent to decide for the moment on the construction of a factory capable of only turning out 300 tons per month, and this course I now propose.

I am certain that as soon as this, the first part of our programme, is executed, and the board can take stock of its success, they will not hesitate to give orders to obtain the necessary plant to increase the output.

To arrive at these results, of which there is not the least doubt, work must be undertaken. To work, plant and material in sufficient quantity are necessary, and I therefore beg the board to give me without delay the necessary instructions and means to enable me to proceed.

This being decided upon, one can, without rashness, predict a brilliant future to your company. What is here written is more over a justification of the heading of the prospectus, calling the Elmore process "a revolution in the copper industry."

I beg of you to accept my high consideration,

The General Manager,

E. SECRETAN.

"After having read the above report we approve the contents, and we declare ourselves very satisfied with what we have seen at Leeds."

L. VIGREUX and C. BOURDON.

The abstract of the specification of Mr. H. Wilde's patent of 1876, for electro-coppered iron rollers, which appeared in the last issue of the ELECTRICAL REVIEW, induces me, as one closely associated with Mr. Wilde in the development of his invention and its successful working, to bring under notice some facts connected with the history of the subject which may be of interest, and correct any wrong impression prevailing as to the value of the burnishing process described in the specification. The principal feature in Mr. Wilde's improvements in the electro-deposition of copper in cylindrical forms was the imparting a rapid rotatory motion to the electrolyte or depositing liquid in which the roller is immersed, in order that fresh particles of the electrolyte might be brought into contact with the electrodes. By this means powerful currents of electricity could be brought to bear upon small surfaces of metal, without detriment to the quality of the copper deposited, while the rate of the deposit is greatly accelerated. This improvement formed the subject of Mr. Wilde's patent of December, 1875, No. 4,515. The copper deposited by the new process was superior in tenacity and other qualities to that produced by any other metallurgical process, as was evident from the turnings off a cylinder, which had the ductility of well annealed copper wire, and could be reeled off during the process of turning in lengths of hundreds of feet. Great density was also given to the electro-copper cylinders by submitting them to the action of a steel burnishing roller, and when no special means were taken to secure adhesion between the metal surfaces, the iron and copper cylinders readily separated themselves by the milling or burnishing process. I have now before me a 400 feet length of a copper wire turning, and an electro-copper cylinder, 36 inches long, and 5 inches in diameter, produced in the manner described, 14 years ago.

As the production of separate copper cylinders was not the principal object Mr. Wilde desired to attain, but a compound roller of iron and copper inseparable from each other, as a substitute for the solid copper rollers used in calico printing, it was found that, by depositing one or more thin coatings of copper on the iron before the thicker or final coating, the internal friction of the copper surfaces caused perfect adhesion between the metals, so that the compound rollers would then withstand the heavy milling and burnishing to which they are subjected in some processes of engraving. Soon after the manufacture of these compound rollers was established it was found that milling of the separate coatings was an unnecessary process, and that the

essential cause of the adhesion of the iron and copper surfaces was the separation of the internal coatings, which could be brought about either by exposing the newly-deposited copper to the action of the air, or by a temporary reversal of the electric current.

During the last 14 years these electro-copper rollers and cylinders have entered largely into the industries of the country for a variety of purposes, and thousands of them are manufactured annually by the Broughton Copper Company, Manchester, to whom Mr. Wilde disposed of his patent rights ten years ago. The rollers and cylinders have been exhibited by the company at several industrial exhibitions, including the Electrical Exhibition at the Crystal Palace in 1882, at which Elmore & Co. were also exhibitors of dynamos and electro-plating apparatus. The last of Mr. Wilde's patents expired in September last, so that the public are now at liberty to use whatever there is of value in them for the electro-deposition of copper cylinders and for other purposes. It may, therefore, be taken as conclusive that the art of producing electro-copper cylinders on a large scale and increasing the density of the copper by the process of milling and burnishing has been well known to the industrial world during the last 14 years, except to Mr. Elmore and the astute financiers who use the name and patents of Elmore to conjure with, and take advantage of the unbounded credulity of the general public in the possibilities of electricity.

John Hill.

16, St. Oswald's Grove, Harpurhey,  
Manchester, November 25th, 1890.

P.S.—I am sending by parcel post small pieces of the wire turning and electro-copper cylinder referred to, which you are at liberty to make use of as you may think proper.—J. H.

[We have received the articles to which Mr. Hill refers in his postscript, and very interesting they are; we only hope that his evidence may be the means of opening the eyes of Elmore shareholders to the true value of the stock they hold.—EDS. ELEC. REV.]

#### Overhead Conductor Regulations.

It will interest your readers to know that two memorials have recently been forwarded to the Board of Trade upon the subject of the regulations relating to overhead conductors. The memorials, of which, at the request of members of the firms interested, I enclose copies, explain themselves.

The Brush Electrical Engineering Company, Limited.

R. PERCY SELLON, Assistant Manager.

November 24th, 1890.

[COPY]

London, November 6th, 1890.

To the Right Hon. Sir EDWARD MICHAEL HICKS-BEACH, Bart.,  
M.P., President of the Board of Trade.

Sir,—We, the undersigned companies, firms and persons, interested in the supply of electricity in the United Kingdom, beg respectfully to memorialise your Board with reference to regulation No. 9 of the regulations for the protection of the public safety, &c., prescribed by the Board of Trade under the provisions of the Electric Lighting Act of 1889.

With reference to this regulation, the undersigned beg leave to state that it is the general experience based upon numerous actual tests, that for pressure up to 2,000 volts, whether alternating or continuous current, a thickness of one-tenth of an inch of dielectric is unnecessary in conductors of small section.

For conductors having a relatively large sectional area, we are satisfied with the expediency of the Board of Trade requirements, but for conductors having a relatively small sectional area, the disproportion between the conductor and the insulation is so excessive, as not only to render the use of such conductors prohibitory in view of their high price, but actually dangerous in the presence of snow and high winds on account of the very large surface presented in proportion to the total weight of the conductor and its covering.

Four of the principal companies interested in this branch of work,

viz.: The Brush Electrical Engineering Company, Limited; Messrs. Crompton and Company, Limited; the India-Rubber and Gutta-Percha Company, Limited; and Messrs. Laing, Wharton and Down Construction Syndicate, Limited, were represented at the experiments carried out at the works of Messrs. Crompton and Company at Chelmsford, by your adviser, Major Cardew, and their representatives were so thoroughly convinced by these experiments of the reasonable character of their request for a modification of the existing rule, that the above-mentioned companies heard of the receipt by Messrs. Crompton and Company of the letter from the Board of Trade, dated May 30th, with the greatest astonishment and regret.

The undersigned beg leave, therefore, most respectfully to request the Board of Trade to give the decision therein communicated their favourable reconsideration, and to suggest that this rule may be modified in accordance with the following:—

Every high-pressure aerial conductor must be continuously insulated with a durable and efficient material, to be approved of by the Board of Trade, and to a thickness of not less than one-seventh part of the actual conductor diameter, in cases where the extreme difference of potential does not exceed 2,000 volts; but for all higher voltages this thickness must be increased in direct proportion to the increase in difference of potential.

In no case must the thickness of insulation be less than one-sixteenth of an inch, and the cables must have an insulation resistance of not less than one megohm per mile per volt of electromotive force when tested in water at 60° Fahr. (after immersion of at least 60 consecutive hours). This insulation must be further efficiently protected on the outside against injury or removal by abrasion. If this insulation or protection be wholly or partly metallic, it must be efficiently connected to earth, so, however, as not to cause undue disturbance to other electric lines or works by electrostatic induction or otherwise.

The undersigned are willing and anxious to conduct any additional tests which the Board of Trade may wish or suggest, in proof of the contentions herein stated.

The undersigned make these representations while fully recognising the necessity in the interests, not only of the public, but also of the electrical industry generally, that all overhead electric lines should be carried out in the safest possible manner.

We have the honour to be, Sir,

Your most obedient servants,

(Signed) THE BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED,  
MESSRS. CROMPTON & CO., LIMITED,  
THE INDIA-RUBBER AND GUTTA-PERCHA COMPANY, LIMITED,  
THE LAING, WHARTON AND DOWN CONSTRUCTION SYNDICATE, LIMITED.

[COPY]

London, November 6th, 1890.

To the RIGHT HON. SIR MICHAEL EDWARD HICKS-BEACH, Bart.,  
M.P., President of the Board of Trade.

Sir,—We, the undersigned companies, firms, and persons interested in the supply of electricity in the United Kingdom, beg respectfully to memorialise your Board with reference to regulations No. 2 and 12 of regulations for the protection of the public safety, &c., prescribed by the Board of Trade under the provisions of the Electric Lighting Act of 1889.

With reference to these regulations the undersigned beg leave to bring before the Board the fact that in conjunction with overhead conductors having a small sectional area of copper, the use of suspending wires is not only necessary, but exceedingly dangerous to public safety, on account of the large surface presented to wind and snow, and the great strain put upon the supports.

It is admitted that this does not apply with so much force to the use of suspending wires with conductors of relatively large sectional area, but the undersigned are strongly of opinion that both in the interests of the electrical industry, and in those of public safety, it is advisable that overhead conductors up to a sectional area of hard-drawn copper, equivalent to 7 No. 16 S.W.G. should be run without suspending wires.

The undersigned beg leave, therefore, most respectfully to request the Board of Trade to give their favourable reconsideration to the foregoing regulations, and to suggest that they may be modified in accordance with the following:—

Clause 2. Every aerial conductor shall be attached to supports at intervals not exceeding 200 feet where the direction of the conductor is straight, or 150 feet where this direction is curved, or where the conductor makes a horizontal angle at the point of support. If suspending wires are used, as required in Clause 12, the above intervals may be increased to 250 feet and 200 feet respectively.

Clause 12. Every aerial high-pressure conductor shall be efficiently suspended by means of non-metallic ligaments to suspending wires, so that the weight of the conductor does not produce in it any sensible stress in the direction of its length, and the insulated conductors and suspending wires, where attached to supports, shall be in contact only with material of highly insulating quality, and shall be so attached and guarded, that in case they break away, it shall not be possible for them to fall away clear of the supports.

Provided that where the aerial high-pressure conductor is equal to, or less than, 7 No. 16 S.W.G., the suspending wires shall not be compulsory if the conductor be of hard drawn copper, or other material of equal strength.

The undersigned are willing and anxious to conduct any tests which the Board of Trade may wish or suggest, in proof of the contentions herein stated.

The undersigned make these representations while fully recognising the necessity in the interests, not only of the public, but also of the electrical industry generally, that all overhead electric lines should be carried out in the safest possible manner.

We have the honour to be, Sir,

Your obedient servants,

(Signed) THE BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

MESSRS. CROMPTON & CO., LIMITED.

THE LAING, WHARTON & DOWN CONSTRUCTION SYNDICATE, LIMITED.

### Single-Cord Telephone Switchboards

We much regret that by an oversight we have not replied sooner to the criticism which appeared in your issue of the 31st October of a particular pattern of single cord board by the Western Electric Company, through Mr. Kingsbury. This board, described in your issue of the 24th October, was selected as being the simplest pattern; it is one of large numbers we have made, to sample received, in which accessibility for adjustment and repair, and certainty of action of the indicator drops, are most considered. Mr. Kingsbury has fallen into the error of assuming that this is the only pattern of board made; the dimensions he gives are wrong, a complete 150 line board has a width of 6 feet 2 inches, and not of 15 feet, as he appears to assert. However desirable compactness may be, accessibility must be considered; still, if we make use of the small annunciators shown on the W. E. board 31st October, the S. C. board will be quite as compact.

For the moment, assuming Mr. Kingsbury's list of connecting and disconnecting operations to be correct, it should be noted that the W. E. operations, even when using speaking and ringing keys, need seven movements in all; the single cord board criticised, requires the same number of movements *without* special speaking and ringing keys, but *the movements are reduced to four*, for connecting and disconnecting two subscribers, if these special keys, or their equivalent, are used. Such S. C. boards with small annunciators, and with special apparatus by which only four operations are needed, we are ready to supply.

Telegraph Manufacturing Company, Limited.

November 25th, 1890.

### High-handed Proceedings—(continued).

We have again been requested to insert the following correspondence, but in future we must either summarise the letters or omit them altogether.

Glasgow, November 18th, 1890.

Wm. Alex. Smith, Esq.

Dear Sir,—I learn from Mr. Laid, law stationer, St. Vincent Street, and Mr. Woolfield, Buchanan Street, that you and Mr. Smith, the secretary of the National Telephone Company, called to buy two of my telephones "for export." It seems a waste of money to offer Mr. Woolfield double the price when, by applying to me, you can get a ship load at even less money. If you will give me your marks and numbers, with shipping port, I shall be very pleased indeed to take your order, and as I have nearly 2,000 lying in the Rue Caumartin, Paris, you need not have to wait long for them. Of course you are well aware that these cannot be introduced into this country as a sale till 9th December, but as you represent the National Telephone Company here that is a difficulty that need not stand in our way. You are aware in March last you and Col.

Jackson gave me an order for some which were delivered within 48 hours from Paris, and further, I may say they will be as much superior to your present telephones as Madame Patti's voice is to that of a broken-winded foxhound. May I expect a report from your engineer soon on the Lacombe cell which you asked from me.

Yours truly,  
A. E. MUIRHEAD.

6, South Hanover Street, Glasgow,  
18th November, 1890.

A. Erskine Muirhead, Esq.,  
Crossmyloof.

Dear Sir,—Your favour of this date has just reached me. I observe it is addressed to me as "Chairman of the Local Board," although I have informed you some time ago that for years no such Board has existed.

You have been incorrectly informed that Mr. Smith and I called on the parties named by you.

I have not seen any telephone from you which have not been tested by us long before I heard of your having anything to do with telephones. As to the efficiency of such telephones, you will excuse me when I say I am in a better position than you are to give an opinion.

The cell which you asked me to test for you has not yet been reported upon, but as soon as I do get a report of it it shall be communicated to you. As far as I can judge of it, it, like the other appliances submitted by you, are modifications of forms well-known to us for years.

Yours respectfully,  
WM. ALEX. SMITH.

Glasgow, November 19th, 1890.

Wm. Alexr. Smith, Esq.

Dear Sir,—I have yours of 18th. I called at shop, and as it was re-asserted that you were the person that called to buy the telephones, I can only ask that you will accept my apology and record it as another extraordinary case of mistaken identity. It is, moreover, very odd that the persons calling should say that by exposing those telephones for sale the shopkeeper was placing himself in a position in which the N. T. Company could claim damages, so it might be well if you consult your secretary and find some one has been acting for you to have it put a stop to, as you are aware that it is perfectly legal for anyone to offer (1) a telephone for sale for export; (2) to sell a telephone that does not infringe the patents of the N. T. Company. As regards your third paragraph *re* the efficiency of the "Ader" and "Berthon" telephones compared with the one in use by the N. T. Company, seeing both of us have very high opinions of our own judgment, I would suggest that if you really want an unbiassed opinion on the merits of the telephones, and to have the matter settled *you* will at hazard name a dozen members of telephones from the Paris Exchange, the editor of the *Herald* or *Citizen* will name 12 from the Glasgow Exchange. Those instruments as they stand will be conveyed to Glasgow and submitted to tests as they stand, not to be in any way touched. You can name six of your own subscribers, and I will name other six, or we can take them also at hazard, and ask them to report the results. I will use the Lacombe cells, of which you ask a sample, for trial. As regards the Kilmarnock affair, seeing we are going to fight a more serious battle, I will again make an offer to show your engineer the four telephones there, and trust if they are what I represent them to be, that you will apologise to Mr. Richmond. If they are infringements of your patent, then by all means proceed with your action; however, you will find them what I say they are, and I beseech you to ask your company to leave off the rôle of private detective, as it requires a capacity they seem to lack. I need not again remind you I am running

bronze wires in the principal centres in Scotland, England, and North of Ireland, to which I am fixing "Ader" and "Berthon" telephones. After the 9th December, no microphone will be used at that date, as the "Ader" receiver is quite ample for any distance below 20 miles; but I again offer you a list of those lines, and an order to your engineer in the respective districts to inspect them, and thereby prevent a massacre of some of your *employés*, who might force their way in to see the telephones uninvited.

A. ERSKINE MUIRHEAD.

The National Telephone Company, Limited,  
Glasgow Offices, Royal Exchange Buildings,  
21st November, 1890.

A. E. Muirhead, Esq.

Dear Sir,—I am directed by Mr. W. A. Smith to acknowledge receipt of yours of 19th inst., and to say that he has nothing to add to his letter in regard to the first portion of what you say.

I have to thank you for renewing your offer to allow our engineer to inspect the telephones erected by you, and shall feel obliged by your forwarding the necessary permission to this office, as well as orders to our engineer to inspect telephones you have erected in other parts of the country.

Yours truly,  
D. JOHNSTONE SMITH,  
*District Secretary.*

Glasgow, November 21st, 1890.

Mr. D. Johnstone Smith,  
Secretary National Telephone  
Company, Limited, Glasgow.

Dear Sir,—A very singular incident has happened, viz., that two gentlemen, thought to be Mr. W. A. Smith and yourself, went into Mr. Woolfield's shop in Buchanan Street, where one of my telephones was exposed in the window, with the enclosed card fixed to it. A very fancy price was offered for a pair, but as Mr. Woolfield could not sell them till 10th December, no business resulted, but the mysterious strangers then gave Mr. Woolfield to understand that by exposing those, even for export, he was doing an act that would bring the N.T. Company on him for damages. As you are the recognised chief of the N.T. Company in this city, perhaps you may see fit to disclaim all knowledge on your part, and that of the N.T. Company, of what I hold to be an interference with the liberty of the subject. As you are, perhaps, well aware, the Caledonian Railway Company's telegraph have at least a dozen different types of those French telephones in their possession. If you are not aware, I now take this opportunity to say I am quite at liberty to advise you of the fact, so that if the N.T. Company think they have a legal right to dictate to the Caledonian Railway for being in possession of those telephones, they can try it. It is patent to everyone that the N.T. Company have in this country tried to fill the vacancy left by the Society of Jesus, in the department of espionage and tyranny.

The S.J. had at least the credit of doing anything, however bad, *well*. Their staff contained the best men in every department. I leave it to you to say if yours is up to this standard. You may think it odd that I should insist in having this matter cleared up. I want to show Mr. Woolfield that I have not put him in a false position by asking him to do something that was illegal. I trust you will leave a reply to this, addressed to me at the bar of Royal Exchange, which I will at once show to Mr. Woolfield.

Yours, &c.,  
A. ERSKINE MUIRHEAD.

I may add that a proof of circular, and also the advertisement now appearing in the *Times*, *Standard*,

*Daily Telegraph, Herald, Scotsman, Citizen, News and Scottish Leader*, were submitted to your London office before insertion.

The National Telephone Company, Limited,  
Glasgow Offices, Royal Exchange Buildings.  
21st November, 1890.

A. E. Muirhead, Esq.

Dear Sir,—I beg to acknowledge receipt of your letter of this date, but regret that I do not see my way to enter into any correspondence regarding this.

Yours truly,

D. JOHNSTONE SMITH,  
*District Secretary.*  
*Per J. D. W.*

Glasgow, November 24th. 1890.

Wm. Alex. Smith, Esq.,  
National Telephone Company's Office,  
Glasgow.

Dear Sir,—As you have at least always replied to me, I cannot be outdone by you in politeness. I now beg to enclose order on Mr. J. Richmond to allow your Mr. Aitken to inspect telephones. As regards Woolfield's affair, the "Flying Dutchman," Wandering Jew, or the German Baron must have paid our city a visit. As regards giving your engineer an order to inspect the other lines I am erecting in various parts of the country, it would (1) simply be impossible for him to overtake them before 10th December, as they are numerous, and are scattered over the country between Inverness and Bristol; (2) and, further, when your company came across Dr. Kelly's wire you were able then to offer him terms that induced him to take your telephone, though I hear that he may change his mind again, so you must excuse me declining to show you my hand when your company are so ready to take advantage of such information.

Your truly,

A. ERSKINE MUIRHEAD.

I shall be glad to hear if you have yet tested the Lacombe cell.

Glasgow, November 24th, 1890.

Mr. D. Johnstone Smith,  
Secretary National Telephone Company,  
Glasgow.

Dear Sir,—Your note of 21st is duly to hand. I shall leave it to others to say whether it is a satisfactory reply to my note of 21st.

A. ERSKINE MUIRHEAD.

I have sent your London office a copy proof of enclosed circular. I may leave for London before I have their reply. If they want to see me they can address me at St. Pancras Hotel.

6, South Hanover Street, Glasgow,  
24th November, 1890.

A. Erskine Muirhead, Esq.,  
Crossmyloof.

Dear Sir,—I am directed by Mr. Wm. Alex. Smith to acknowledge receipt of your favour of this date, enclosing order to inspect the instruments erected at Mr. Richmond's, for which he desires to thank you.

He takes good note that you now withdraw from your offer to give similar facilities to the telephone engineers in other parts of the country.

The report on the Lacombe cell is fairly satisfactory, but, of course, its durability can only be tested after a year or two's experience of the same.

Yours faithfully,

D. CAMPBELL.

#### Telephonic Research.

I suppose it has also seemed peculiar to you that none of the text-books, &c., on telephones state the source from which the information is derived that Mr. Yeates, of Dublin, experimented with the Reis telephone, and placed a drop of water between the electrodes. To-day, while going through a mechanical magazine, I noticed an article which is very suggestive, because it says that the *Dublin Medical Press* (presumably of 1864) contains a description of experiments with an acoustic telegraph (presumably Reis's), and says that a membrane at the receiving station was thrown into vibrations corresponding to the vibrations of the membrane at the transmitting station. I enclose the article (in German) just as it appears in journal found by me:—

*Zeitschrift des Architekten Vereins für das Königreich Hannover*,  
A.D., 1866, Vol. XII., page 147.

Neues System A Rustischen Telegraphie. Die *Dublin Medical Press* veröffentlicht einen Artikel über diesen neuen Apparat welcher gestattet die Töne der menschlichen Stimme nach einem entfernten Orte zu übertragen. Man spricht in ein Rohr hinein nahe welchem eine Membrane angespannt ist deren Schwingungen durch den leitenden Draht auf eine gleiche Membrane an der Endstation übertragen werden. Durch die gleichen Schwingungen wird derselbe Ton hervorgebracht und so soll es möglich sein in der That mit einem anderen Welttheile ein Gespräch zu führen.

Article said to be taken from *Nouvelles Annales de la Construction*, 1864, January to September, page 39.

I am not at present in a position to consult the *Dublin Medical Press* (it does not appear to be a widely-disseminated journal, else we would have heard of it ere this). I suppose you will consider the matter of sufficient importance to consult the *Dublin Medical Press*, and give what it states in your Journal? I notice that someone has brought up the *Didaskalia* as being a new thing. I trust I'm not in same boat. Anyhow, the article in German journal (copied from French journal) ought to settle question that Reis had in view transmission of articulate speech. In this I'm a follower of Prof. S. P. Thompson.

A. M. Tanner.

Berne, November 21st, 1890.

**Australian Cables.**—The Hon. John Gavan Duffy, Postmaster-General to the new Cabinet of Victoria, has expressed himself in favour of the cable guarantee, notwithstanding the refusal of Queensland and New Zealand to bear a share.

Public opinion is gradually beginning to assert itself in the mother country as to the desirability of a direct cable from Canada to Australia, says the *Toronto Empire* of November 17th. Readers are doubtless familiar with the discussion which took place in the English Press this summer on this question, and the timely action of Mr. Sanford Fleming, impressing the advantages of a Pacific cable, has already had important bearings. The great shipping agency, Lloyd's, has taken a decided stand in the matter, as the following extract from a letter received by Mr. Fleming to-day from Mr. H. M. Hozier, secretary of that body, shows:—I ought to inform you that my committee have personally drawn the attention of the Prime Minister in this country and of the Chancellor of the Exchequer to the necessity of an alternative telegraphic route to Australia and the East by means of a telegraphic cable across the Pacific, and I am sure that my committee will be most happy to bring this matter forward and give it their assistance in every way in their power on all occasions.

## OVERHEAD LINES AND THE BOARD OF TRADE.

THE two memorials to the Board of Trade, copies of which were published in the correspondence columns of our last issue, show that a wide difference of opinion exists between that Department and some important manufacturing and contracting firms with regard to the precautions necessary for the erection of a safe overhead line. Whilst agreeing with the memorialists that a change is certainly necessary, we cannot help thinking that they have not made as good a case as was possible; and we hope, therefore, that if, as is probable, the Chamber of Commerce takes the matter up, it will, before addressing the Board of Trade, make an exhaustive enquiry; and by obtaining the views of all manufacturers and contractors who have had practical experience with overhead conductors, be enabled to present a strong and well-stated case. Had such a plan been followed by the committee of the Council of the Institution of Electrical Engineers, when the regulations were first submitted to them, the need for amendments so soon after the issue of the rules ought never to have arisen; but, instead of acting in this manner, a committee of gentlemen, who were either without the necessary experience, or had not sufficient personal interest in the questions involved, appear to have approved of the proposed regulations in the name of the whole trade, without ever realising in the slightest degree what it was to which they were agreeing. Naturally this approval of the regulations may be used as an argument against the proposed amendments, and it therefore behoves the trade generally to try and arrange a new *modus operandi* by which they shall secure to themselves the right of being consulted by the Board of Trade before any regulations affecting their business are promulgated.

The first memorial deals with the regulation specifying the thickness of the dielectric, and a brief consideration of the requirements of a safe overhead conductor shows that these are; (1) a sufficiently

high insulation resistance to render accidents practically impossible through direct leakage, if the outer covering of the cable comes in contact with a human being or another wire; (2) a sufficient thickness of insulating material to allow of the necessary handling during erection without damage to the cable; and (3) the protection of linesmen and others from shocks due to the discharge from the exterior surface of the cable of the charge which is induced thereon.

So far as accidents from direct leakage are concerned, ample experience has been gained in working high-pressure alternating circuits underground to show that a thickness of one-tenth of an inch of insulating material, if of suitable quality, is quite unnecessary for the smaller sized conductors; and we may here draw attention to the fact that, so far as guarding against accidents from this cause is concerned, the Board of Trade regulations are quite insufficient, since they specify a uniform thickness of dielectric, irrespective of the size of the conductor, or of the nature of the insulating material employed. The only reasonable form of specification for dealing with this condition is such an one as is proposed in the memorial, viz., that the cables shall have at least a certain minimum insulation resistance per mile, when tested under the best conditions for discovering the existence of faults.

The insulation resistance proposed by the memorialists appears to us sufficiently high to meet all practical requirements, and if a clause were added specifying that during immersion the cable should be subjected to a difference of potential at least equal to that at which it is to be used, we think that no reasonable objections could be offered to the proposed amendment on the score of danger from direct leakage.

The second requirement has to do with the mechanical strength of the insulating material, and here again the experience of all work done, whether indoor or outdoor, underground or overhead, shows that small cables with much thinner insulation than that specified can withstand a considerable amount of rough usage.

Many of us have seen cables with even less than a

sixteenth of an inch of insulating material pulled into pipes, bent round corners of small radius, straightened out again, and subjected to other such treatment without injury; and, were it only this that had to be looked to, we would say that the thickness now suggested was more than was necessary; but there is another matter, which is really one for manufacturers to speak on, and is dependent on the excellence of their machinery, and the care with which their work is done, and that is the difficulty of being absolutely certain that throughout a long length of cable the covering is perfectly even and homogeneous. We believe that excellent results are now obtained in this respect, but for all that we think that, when high pressures are to be used, it is well to err a little on the safe side. A fault due to a slight unevenness in the covering would not show any perceptible difference in the measured insulation resistance; but the test at high pressure already suggested should discover it, if sufficiently bad to be in the slightest degree a cause of danger; and this test, together with the thickness of dielectric now proposed, should be a sufficient safeguard against accidents caused by mechanical faults.

Generally speaking, so far as the two conditions of safety already spoken of are concerned, there is no reason why any difference should be made between underground and overhead cables; and it is therefore, we suppose, with a view to guarding against accidents from discharge that the greater thickness of dielectric is specified. This particular source of danger does not appear to have received the consideration due to it; otherwise the attempt to get rid of it by simply thickening the insulation would not have been made. It is true that an increase in the thickness of the dielectric will decrease the discharge, other things being equal; but a far more important factor in practice is the extent of surface in electrical contact with the discharging circuit. When the outer covering of the cable is dry, and therefore the contact surface is practically limited to the amount covered, say, by a man's hand, no unpleasant results need be apprehended with the ordinary class of cable and a pressure of 2,000 volts; but should the outer covering be wet, so that the surface is a fairly good conductor, the man's hand would really be in contact with a considerable area, and an unpleasant shock would certainly result, even with cables covered with a tenth of an inch or more of insulating material. We are not aware of any exact measurements having been made; and as it is not desirable that they should be first made, when a human being is the measuring instrument, we would commend this matter to the notice of manufacturers and others, who have the necessary appliances for making tests, in the hope that they will be able to supply further information.

The insulated suspending wire, which is connected at frequent intervals by non-metallic ligaments to the outer coating of the cable, will, when these ligaments are damp, be just as unpleasant to touch as the cable itself; being, in fact, under those conditions, equivalent to a metallic sheathing. Now, we find it specified that when a metallic covering is used, that covering shall be

efficiently connected to earth; and the same reasoning, which shows this to be necessary, should also require the earthing of all suspension wires. Such a course of action, by providing an easier path for a discharge than through a human body, would supply the necessary safeguards against accident.

The other regulation, to which exception is taken, is that relating to the use of suspending wires; and here we consider that a grave mistake has been made, since the Board of Trade is asked to make the use of suspending wires optional with cables where conductors are not larger than 7 No. 16; whilst no notice is taken of the regulation concerning the wind pressure to be allowed for, a regulation which, if it remains in force, will render the proposed alteration inoperative; since, as a little calculation would have shown, these smaller cables cannot be used without suspending wires for spans for anything like 200 feet, when a wind pressure of 50 lbs. per square foot, and a factor of safety of six have to be allowed for. We do not propose to enter into any discussion of this question, as in a recent issue\* we printed an article on this subject by Mr. Russell, which showed how much the requirements of the Board of Trade were in excess of what has been previously considered sufficient for safe work; but we think that all efforts should be directed to getting the wind-pressure clause amended, and that until this is done, it is futile to discuss the question as to whether suspending wires are necessary or not in particular cases.

In concluding our present remarks, we would congratulate the trade on the fact of some steps having now been taken to get these regulations amended; steps which, we hope, will lead to a more satisfactory arrangement. We are, however, surprised that the firms whose signatures are appended to these memorials should have been content to put their case before the Board of Trade in such a feeble manner; more especially when we consider that two of them are connected with the manufacture of cables, and should have sufficient experience to enable them to present a much more forcible memorial, and one that could not but carry great weight with it.

---

#### Galvanometers.

THE proceedings of the Physical Society recently published, contain the interesting paper of Prof. Ayrton, Mr. T. Mather and Mr. Sumpner on "Galvanometers." The whole history of this valuable and indispensable piece of electrical apparatus would form a voluminous work, and might be appropriately dealt with by that indefatigable electrical historian, Prof. Silvanus Thompson. Attention to various points of detail has vastly improved the original form of the Thomson reflecting instrument, though it is surprising how closely in general form the early patterns have been (and wisely so) adhered to. There is still room for improvement, however; the hinging of the coil frames is one most noticeable change that has been marked within the last 20 years, but we find that the absurd arrangement of bringing out the coil

---

\* ELECTRICAL REVIEW, 24th October, p. 489.

ends near the centre of the coils is still adhered to, the result being that the coils cannot be swung on their hinges without having to disconnect the ends of the wires from the terminals to which they are attached; if this is not done the spiral connections are pulled out of shape, and in any case are made very untidy. The spiral connections ought, of course, all to be led to and brought out close to the hinges where the movement is least, and we are surprised that this has never been done.

#### Submarine Telephony.

IT is surprising how little the conditions for telephonic working through underground or submarine wires seem to be grasped by numerous so-called electricians; one would have imagined that the law was as well known as that of Ohm. That the product of the total capacity in microfarads and the total resistance in ohms of the line, or its "KR," must not exceed a certain value is a simple and easily recollected law. What this value is, depends upon circumstances; but its average value for good speaking is about 10,000. This figure is known to be correct as the result of numerous experiments, and it disposes of the absurd notion that some people have, that telephoning through a cable several hundred miles long is possible.

#### The Censorship of the Board of Trade.

A CORRESPONDENT writes:—"In the latter part of one of your leading articles entitled 'State Control,' the action of the Board of Trade with reference to electric lighting is severely criticised, but not so severely as it deserves, for that would be impossible. Your remarks would bear repetition again with special reference to the overhead wire question. I think it perfectly scandalous that after electric lighting has reached its present stage of progress by private enterprise and individual effort, the Government should step in with its grandmotherly legislation and restrictive policy and so hinder future progress. But it is always the same. Officialism does act always so, must in fact act so, though people cannot see it until by getting the Government to interfere in their affairs they make a rod for their own backs. The scientific adviser to the Board of Trade knows nothing about practical electric lighting, save what those he now dictates to have taught him, small claims, I think, for so important a position."

#### Projected New Telegraph Lines.

THE *South American Journal* of 29th ult. says:—"Mr. E. Barra has applied to the Government of the Argentine Republic for the privilege to build a line of telegraph from Buenos Ayres to the Cordillera, where it would join another line to the Pacific. This line is intended to compete with the Transandine Telegraph." It is also announced that the *Diario Oficial* of October 30th contains a ministerial resolution issued by the Department of Public Instruction, Posts and Telegraphs, authorising the Western and Brazilian Telegraph Company to lay a duplicate cable along the coast of Brazil. The Chilean Government has accepted a tender for the construction of a line of telegraph between Tongoi and Tamayo.

#### Insulation of Under- ground Lines.

AT a recent meeting of the Berlin Electro-Technical Society, M. Grauwinkel read a paper on the condition of underground lines belonging to the Administration of Posts and Telegraphs of the German Empire, describing at the same time the system adopted in the various tests. In contrasting the results of tests taken during 1889 with those of former years, the author is forced to come to the conclusion that the much lower insulation observed in the gutta-percha core more recently laid down, as compared with the insulation obtained originally on the older lines, is due to nothing else but the inferior quality of the gutta-percha now employed; a consequence resulting from the enormous demand for this material.

#### The Testing of Insulated Wires and Cables.

THE first instalment of a series of articles under the heading of "A Practical Guide to the Testing of Insulated Wires and Cables," written by Mr. Herbert L. Webb, appears in the *New York Electrical Engineer* for November 19th, 1890. So far as the subject is at present carried, we fail to see that the treatment is in any degree more simple than that to be found in many text-books, Culley, for example, although the *raison d'être* of the article is nominally for the purpose of assisting the "budding expert" to grasp the rudiments of electrical testing. Perhaps as the matter advances we may find reason to alter our opinion. We must admit that it is rather early to come to a conclusion.

#### A Candid Statement.

IT is not often that a journal devoted to gas matters makes a candid statement regarding electric lighting, but the *Gas World* in its last issue has done so. In referring to the financial position of the Swan United Electric Light Company, our contemporary says:—"Go where we will, however, this fact stares us in the face, that electric light companies are getting customers in quarters where formerly gas reigned supreme. Whether they will be able to retain these customers, or whether these customers will continue to pay the high price which must be charged to earn dividends, are different questions. All we can say is, that when the two illuminants come into competition the gas shareholder does not suffer, that is, if the manager or engineer keeps abreast of the times and pushes business in quarters hitherto neglected."

#### The Electro- Deposition of Copper.

THE lengthy letter of Mr. Desmond G. FitzGerald, which appears in our correspondence columns, relieves us of the necessity of replying at length to an esteemed trans-Atlantic contemporary, to whose criticisms we briefly referred in our last number. We would recommend both the *New York Electrical Engineer* and Mr. Stepney Rawson to peruse Mr. FitzGerald's communication, which may tend to make both parties moderate their transports. In connection with this matter we cannot refrain from again mentioning how curiously alike are the contents of Mr. Rawson's recent letter and our contemporary's leader.

## SOME FACTS CONCERNING GUTTA-PERCHA.

In a previous issue (November 21st) we gave a brief description of the conditions attending the gutta-percha industry. The last number (22nd November) of *La Lumière Electrique* contains the first instalment of an article from the pen of M. Sérullas upon the same subject. The author, it appears, is exceptionally well qualified to discuss the question in all its bearings, as not only has he made a special study of the gutta-percha trees, from a botanical point of view, but he was also engaged, between the years 1884 and 1889, in extensive exploration and comprehensive research throughout the gutta-percha producing districts.

The author describes the extirpation of certain varieties of the gutta-percha tree, and explains the difficulty now experienced in obtaining the best gums in any appreciable quantity. He incidentally mentions the fact that two French manufacturing companies were compelled to abstain from competing for cables between France and the north coast of Africa, recently offered to tender by the French Government, owing to the scarcity of gutta-percha of a suitable quality.

M. Sérullas affirms that absolutely no percha, free from adulteration with inferior mixtures, now leaves the forests, and he describes how the natives bring to their villages, for the purpose of general mixing, all sorts and conditions of low-class gums. He further shows that the second-class gums are becoming as scarce as the better variety, and that now the percha quoted as being of the best quality is not even equal to the classes which originally figured as third rate.

Although, the author continues, many European merchants, at the centres of exportation, pride themselves on their intimate knowledge of the attributes of the various gums which come under their notice, they are but children in the hands of the native collectors and of the Chinese middleman. And in addition to the devices and tricks which the gums are subjected to, the difficulties attending the selection of gutta-percha are further increased by the great differences presented by the same species due to the particular locality of growth, the age of the plant, and the method and season of collection. It is consequently impossible to place any reliance upon the supposed quality of gutta-percha, even when carefully selected for employment in its most important rôle, that is to say, as the dielectric in submarine cables; the adulteration or mixture of various and inferior gums follows no rule, no proportion, either as to quality, quantity, or species.

M. Sérullas states that after a laboured study of the various gums, he has succeeded in arriving at an analytical method, by which he is able to determine the qualities of mixtures of gums recently collected; but this method cannot be depended upon to indicate the quantities of the component parts, and it is completely at fault with regard to old mixtures. With the latter, chemical reactions, electrical tests, spectral analyses, and microscopical examination, are ineffectual, although in certain cases the presence of secondary resins, and the results of the separation of the glucose colouring matters which stain the gums, may indicate the existence of such and such a gum in the mixture, but that is all.

A gum, such as that obtained from the *Minuesops Balata*, almost entirely composed of the fundamental hydro-carbons of the guttas, is not invariably the one which will be longest in changing. A remarkable fact connected with gutta-percha is that two mixtures, exactly similar in all respects, are quite likely to give very different results after the lapse of a few months. Hence, M. Sérullas says, it is not to be wondered at that different portions of a core, in all of which the same percha is supposed to be used, may develop very dissimilar characteristics, even in a comparatively short period.

Gums of low quality, even when pure, behave with regard to their constancy and lasting properties in the same manner as mixtures. And with respect to oxida-

tion, and to the combination of elements and atomic distribution, a very interesting question presents itself as to the changes in molecular equilibrium to which these substances are subject.

The *Isonandra Gutta*, or *Isonandra Percha*, the most valuable of the family of guttas, is also the one most infrequently met with. It will not grow near the sea, nor at a height of more than 200 feet above the sea level, and, although it requires constant humidity, it does not thrive in the neighbourhood of stagnant water. It is almost exclusively found in shallow ravines where the soil is of a compact clay, and where the roots can seek running water. Other reasons besides those connected with climate and locality combine to make the *Isonandra* scarce. The reproduction of the species by seed never occurs at any considerable distance, the young plants being always found grouped close around the adult trees. The seeds not only very quickly lose their germinative power but when ripe are eagerly sought for by many of the birds and beasts of the forests.

In addition to the wholesale cutting down of adult trees, and of the second growth before it attained maturity, for it has been the practice for some considerable time to cut trees only 10 or 11 years old, the reckless clearing and burning of the forests for the cultivation of gambier, and in Borneo for coffee planting, in Sumatra for coffee growing, and in the Malacca peninsula in the search for tin, have contributed towards the extirpation of the *Isonandra*, for though the jungle grows again after the forests have been burned, the gutta-percha trees do not reappear where fire has once passed.

The serious position in which submarine telegraphy is placed owing to the complete extirpation of the only tree producing a gutta-percha suitable for the core of submarine cables, and the utter failure of all attempts to replace it, for this especial purpose, either by low class gums, or by nondescript preparations, is clearly set forth by M. Sérullas. He points out that all these would be substitutes, are precisely lacking in the very quality which gives its great value to pure gutta-percha of the best variety when used as a dielectric under water, that is to say, its almost indefinite immutability. The author has a good deal to say on this point, but we need not follow him further in this direction, since there is nothing very novel in his remarks, and his contention scarcely admits of controversy.

Some idea may be gained of the tremendous inroads made upon the gutta-percha producing districts of Malaysia from the following figures:—

In 1845 there were imported to Europe 19,836 lbs. of gutta-percha. In 1851 the amount barely reached 30,856 lbs.; but in 1855, when collecting commenced to spread throughout the archipelago, the quantity considerably exceeded 661,200 lbs.

In 1857, there were placed on the Amsterdam market alone nearly 551,000 pounds, which was valued at 3.28 francs per kilogramme, or, roughly, at 1s. 3d. per pound.

In 1870, Malacca and Selangore alone, exported rather more than 220,400 pounds.

In 1879, the quantity imported to Europe reached the enormous total of 4,408,000 pounds; of this amount, Sumatra contributed 297,540 pounds, Borneo 2,865,200 pounds, and the remainder principally came from Padang and Perak.

The gutta-percha brought to the Singapore markets in 1879-80 was double the quantity sold in that place in 1869-70; but since 1880 there has been a considerable and continual decrease. M. Sérullas is not very explicit as to the dates when the various districts despoiled of gutta-percha trees ceased exportation. This information would, perhaps, be difficult to obtain with any degree of accuracy; but we gather that all collecting ceased in Singapore in 1857, in Malacca and Selangore about 1875, and in Perak between 1883 and 1884. These districts, it should be remembered, had been amongst the most fruitful in their yield.

It was not until 1883 that the British Government ordered the cessation of gutta-percha collecting throughout their possessions in the Straits; too late, indeed,

to preserve the existence of the tree. Unfortunately, the method adopted by the natives of collecting the gums attracted but little attention on the part of European Governments until too late to avoid the consequences. The real yield of the gutta-percha tree was unknown until quite recently, and such information as was given, notably, by Dennys, Morton, Von Gaffron, and Schlimmer, led to exaggerated ideas as to the inexhaustible resources of Malaysian forests.

The author, in dealing with the very important question of the yield of sap per tree, points out that even the more moderate estimates of Dr. Burck are greatly in excess of the actuality, and he lays some stress upon the fact that whereas this well-known botanist could only have examined a few trees, and these not under the most favourable conditions, he, M. Sérullas, experimented upon more than 6,000 *Isonandra* of various ages and in different localities.

The *Isonandra* of good quality is not fully grown till 28 or 30 years of age. It then commences to flower, an operation repeated every two years. When mature, the trunk is generally cylindrical, having a circumference of about three feet at a height of 5 feet from the ground. The adult *Isonandra*, under ordinary circumstances, supplies about one-third of a pound of sap. Adopting this figure, M. Sérullas estimates the number of *Isonandra* cut down in Borneo alone during the year 1879 at not much less than five millions.

In attempting to arrive, by reference to the quantity of gum of the best quality exported from Malaysia, at some idea of the destruction of *Isonandra*, it must be remembered that the wholesale cutting of adult trees necessitated, in order to keep up the supply, enormous inroads upon the immature plants, which naturally gave very much less sap per tree than the fully-grown ones.

(To be continued.)

## ON THE NEW STANDARD EDISON ELECTROLYTIC METER.\*

By A. E. KENNELLY and R. S. WHITE.

SINCE the last meeting of the association, the new and improved pattern of the Edison meter has been decided upon, received Mr. Edison's approval, and has been completed by the Edison General Electric Company. It has already been introduced into two stations, Brooklyn and Winnipeg, and the reports upon its behaviour in each case are excellent. There are four standard sizes of these 3-wire meters, Nos. 1, 2, 4 and 8, designed to supply 40, 80, 160 and 320 lamps respectively. Meters of larger capacity than these are made specially. In all sizes, however, the bottles and plates are alike, and of the pattern shown. The spools, too, are alike, making the resistance of the bottle circuit the same in every meter, and the drop of potential in the shunt at full load is the same, namely, four-tenths of a volt.

It is arranged that in the smallest or No. 1 meter, each milligramme of weight transferred represents one ampère-hour of supply, and the transfer is 10 milligrammes per hour on full load. Similarly every meter transfers 10 milligrammes per hour at full load, so that each milligramme of transfer in a No. 8 meter represents eight ampère-hours, and in a No. 4 meter four ampère hours, the number of the meter being the index of the supply in each case.

This greatly simplifies the system, reduces the weight of bottles that have to be daily transported, reduces the stock that the station has to keep in hand, makes only one balance requisite instead of two, and with reasonable care the use of a separate multiplier for each size of meter is not found to be an inconvenience. The

objection has been urged against the system that there is danger in making one milligramme of transfer stand for so large a unit as eight ampère-hours in the No. 8 meter, since an error in weighing or in the proportions of the meter would result in an error in the bill eight times as great as the same discrepancies would produce in a No. 1 meter. Even granting the validity of the objection, however, it is evident that since meters are introduced in the capacity proportionate to their duty, the error in the No. 8 meter bill will only bear the same ratio to the whole amount charged, that the smaller No. 1 error bears to its bill. As a matter of experiment, taking, for instance, a series of tests made with the meters by one of the writers at Brooklyn, the records of a set of Nos. 1, 2, 4 and 8 meters, worked in series, and at intervals for a week on half load for the smallest, or five ampères, one-sixteenth of the load for the largest, showed practically the same results, the No. 8 meter under indicating about 2 per cent.

This high degree of relative accuracy, setting aside all questions of care and skill, is secured by three things; The first is a higher degree of absolute accuracy in general. The old pattern meter is universally admitted to be a faithful and accurate instrument, but the intrinsic accuracy of the new pattern is about three times as great. The only chance for error in the operation of the electrolytic meter, accidents aside, is the variation of resistance in the bottle whereby the true ratio between the currents in the bottle and shunt circuits is upset. The extent of such a disturbance of course depends upon the relative proportions of resistance in bottle and spool. Suppose it were possible for the new bottle to even double its resistance and to become 5 ohms instead of 2.5 ohms, at normal temperature. In circuit with a spool of 46½ ohms, such a change would only upset the balance, and make the record in defect 5 per cent. In the old pattern meter the doubling of the bottle resistance, were such a variation to be expected, would make the readings 15 per cent. in defect.

The second preventive of error in the larger sizes is due to the uniformity in the size of plate. A cause of discrepancy has always existed in a slight gain of the plates in weight independently of the current's action and due to their oxidation superficially. With care this source of error has always been minimised, but with the old meters it increased with the size of the meter, since a larger plate offered a larger surface to oxidation. In the new patterns it is of course a fixed amount in all sizes, and owing to the small area of plate, is in any case very small.

The third precaution against error in the larger sizes is the use of duplicate bottles in the Nos. 4 and 8, as mutual checks which are not required in the Nos. 1 and 2.

Another improvement is in the plates. These are castings of pure zinc alloyed with 2 per cent. by weight of pure mercury. This amalgam has the advantage of being more readily brought into good condition for use than the rolled plate; the trouble of varnishing is also saved.

The only other noteworthy change has been in the solution, which is about twice as dense as in the old bottles.

Mr. Edison has recently completed a mechanical meter on the pattern of one of his early patents in that direction. This instrument is a small motor delicately constructed. The armature commences to rotate as soon as one lamp in the supplied circuit is turned on. The rotation accelerates as more lamps are lit, until at the full load of 20 lamps the speed is 600 revolutions per minute. A counter worked from the armature shaft records the number of rotations, and on duly proportioned dials the supply. The field magnets are kept charged by a feeble current from the mains, while the main current passes through a shunt as in the electrolytic meter, and from the shunt terminals wires pass to the armature. The drop of potential in the shunt at full load is 1.5 volts. The model, though complete in itself, will be slightly modified in detail to suit commercial use, and will then be available for such cases

\* Read at the Convention of the Association of Edison Illuminating Companies.

where a mechanical meter is desirable. Mr. Edison does not consider that a mechanical meter can possibly be as cheap or as reliable as the electrolytic meter, firstly, owing to the necessary frictional error which makes the record too low for very light loads and low speeds, and, secondly, owing to the mechanical wear and tear of the working parts, which will need attention and exchange from time to time; but there are cases in which a direct-reading mechanical meter will be an advantage, and he expects that from the tests and behaviour of this model it will serve the purposes.

The conclusions, drawn from an experience of one year with the standard Edison meter, are as follows:—During the year's work with the new standard meter, we have taken 4,088 incandescent, 853 arc lights, and 244 motor readings—a total of 5,185, and have obtained uniformly good results. In a large number of cases customers have kept tally of lamp-hours, and in every instance expressed themselves as satisfied. A considerable number of tests have shown marked accuracy. The greater despatch and care with which the meter work can be performed has been abundantly shown. The use of small and uniform plates secure, by the balance method, doubled accuracy in weighing and the elimination of the oxidisation error. In brief, our experience with the standard meter shows improved ease and economy in operation with more uniform and accurate results. In so far as a chemical meter "fills the bill," little remains to be said.

It may be interesting to note the use of four Aron meters on our circuit for the past year. The frank, open countenances of these meters have won the favour of the meter man and the confidence of the customer. We may conclude, then, it is in the line of a direct reading dial meter that we are to look for the next advance in the commercial treatment of the meter question.

### THE ELECTRIC RESISTANCE OF BISMUTH IN A MAGNETIC FIELD.

MONS. A. LEDUC has recently been engaged on the problem of determining a mathematical formula by means of which it would be possible to calculate the resistance

$$R_{M,t}$$

of a wire of bismuth placed in a magnetic field of value,  $M$ , and at a temperature,  $t^{\circ}$ , in terms of its resistance,  $R_0$ , at  $0^{\circ}$ , outside the field.

The resistance at  $t^{\circ}$ , outside the field, is well expressed by the general formula

$$R_t = R_0 (1 + k t + m t^2 + n t^3)$$

in which the coefficients vary according to the character of the specimen of bismuth that is being examined.

Under the influence of the field the unit of resistance has been shown to be subject to an augmentation,  $Z$ , which is given by the hyperbolic equation

$$Z^2 + \beta Z - \alpha M^2 = 0.*$$

And this is of such a kind that if we assume  $b = \frac{\beta}{2}$  we finally get the formula

$$R_{M,t} = R_0 (1 + k t + m t^2 + n t^3) (1 - b + \sqrt{b^2 + \alpha M^2}) \quad (1)$$

Leduc has been examining the influence of temperature upon the coefficients  $\alpha$  and  $b$ , and at a recent meeting of the Paris Academy of Science he read a paper embodying the results of his research.

The specimens of bismuth which were examined were of the following nature:—One was a fine thread of metal obtained by the electrolysis of the nitrate; the

other two were wires wound in the form of a double spiral, and were made from metal that had been fused and run into tubes, which were then placed in an oil bath at  $280^{\circ} \text{C.}$ , and slowly cooled down. The metal from which one of these spirals was prepared was the pure bismuth of commerce; in the other case it was specially prepared from the pharmaceutical sub-nitrate by solution in nitric acid, precipitation with ammonia, and subsequent reduction with cyanide of potassium.

On the whole, the results obtained for those specimens were very nearly the same; but the specimen last described had a sensitiveness to magnetism which was superior by 10 per cent. to that of the first, and by about 15 per cent. to that of the second. On the other hand, its resistance outside the field presents a minimum towards  $23^{\circ} \text{C.}$  This specimen was considered by Leduc to be the purest of the three.

The coefficients were both found to vary with the temperature, as indicated in the table below. The influence of temperature diminishes slightly as the intensity of the field increases.

$t$	$18^{\circ}$	$44.7^{\circ}$	$100^{\circ}$	$130.8^{\circ}$	$157.5^{\circ}$
$\alpha \cdot 10^{11}$	221	143	55	33	22
$\beta \cdot 10^3$	263	275	301	316	342

The values of  $\beta$  are given approximately by the formula

$$\beta = 0.258 (1 + 0.000907 \cdot t + 0.00000723 \cdot t^2) \dots\dots\dots (2.)$$

Those of  $\alpha \times 10^{11}$  are given by the formula

$$\alpha \cdot 10^{11} = 288.5 (1 - 0.01455 \cdot t + 808 \cdot 10^{-7} \cdot t^2 - 163 \cdot 10^{-9} \cdot t^3) \dots\dots\dots (3.)$$

But this equation indicates at about temperature  $165^{\circ}$  a change in the curve which experiment does not confirm and according to it  $\alpha$  disappears at about  $209^{\circ} \text{C.}$

Leduc's results are well illustrated by the equation

$$\alpha \cdot 10^{11} = 288.5 (1 - 0.0145 \cdot t + 819 \cdot 10^{-7} \cdot t^2) \dots\dots\dots (4.)$$

$$- 194 \cdot 10^{-7} \cdot t^3 + 141 \cdot 10^{-12} \cdot t^4)$$

According to this equation  $\alpha$  disappears at about  $261^{\circ} \text{C.}$

In spite of the somewhat empirical character of this function and the uncertainty existing in the determination of its coefficients, Leduc considers that  $\alpha$  does disappear and that the influence of magnetism vanishes at the fusing point of bismuth.

The resistance of a specimen of bismuth may be calculated within the limits of Leduc's experiments by means of the formulæ (1), (2) and (3), and probably at temperatures lower than the melting point by means of the formulæ (1), (2) and (4).

It may be added that in the above case we have

$$k = - 57.10^{-5}$$

$$m = 125.10^{-7}$$

$$n = - 10^{-8}$$

In applying this property of bismuth to the measurement of magnetic fields it will be sufficient to know the variations of  $\alpha$  and  $\beta$  at the ordinary temperature, and then they may be expressed by the binomial formulæ.

Thus if we express  $Z$  in thousandths, we may in such an actual case merely take

$$\alpha = 0.00231 [1 - 0.0153 (t - 15)]$$

$$b = 131 [1 + 0.0011 (t - 15)]$$

And this will only necessitate four measurements of  $Z$ , made in two known fields, at, for example,  $10^{\circ}$  and  $20^{\circ} \text{C.}$

**Lighting the Meuse Forts.**—The War Department in Belgium recently appointed a commission to investigate the subject of employing electric projectors for the defence of the forts of the Meuse. The apparatus, which has been made by the Société de la Meuse, was placed in armoured turrets, which protect the *personnel*, and the current was supplied by a dynamo driven by a gas engine. The report of the commission has not yet been published.

THERMO-ELECTRICAL RESEARCHES.

By MESSRS. CHASSAGNY AND ABRAHAM.\*

IN the course of our study of the thermo-electrical elements, the comparison of several couples formed of different metals has furnished us with a valuable means of checking the accuracy of our measurements. This system of check consists in the fact that the values obtained verify very accurately the law of the intermediate metals.

For the known temperatures of the junctions we get, between the electromotive forces of the couples formed by three metals, A, B, C, the relation  $E(A\ C) = E(A\ B) + E(B\ C)$ .

The experiments were arranged as described in a former article.† In order to ensure the same temperature at the heated junctions, the wires of the metals under consideration were soldered at one end into the same mass of copper. The other extremities, which were soldered to copper wires, were kept in vessels of ice insulated by wedges of paraffin.

The experiments related to couples formed of the following metals:—iron, platinum alloyed with 10 per cent. of rhodium; copper, pure platinum.

We will now give the results of an experiment in which the junction was placed in the vapour of boiling water:—

COUPLES.	Electromotive forces observed. volts.
Iron-platinum alloyed with rhodium ...	0.0008945
Platinum alloyed with rhodium-copper ...	0.0001980
platinum alloyed with rhodium-platinum ...	0.0007897

From these quantities we deduce for the electromotive forces of the couples iron-copper, iron-platinum, and copper-platinum, the following values, opposite which we have placed those that were observed directly.

Couples.	Electromotive Forces.	
	Calculated.	Observed.
	Volts.	Volts.
Iron-copper ...	0.0010925	0.0010926
Iron-platinum ...	0.0016842	0.0016842
Copper-platinum ...	0.0005917	0.0005917

This system of check, which was necessary for the continuation of our researches, shows, at the same time the degree of exactness of the measurements.‡

THE ELECTRIC LIGHT AND THE PARIS  
MUNICIPAL COUNCIL.

AT the last meeting of the Paris Municipal Council, it was established that the fire at a café on the boulevard was occasioned by too high electrical tension, and numerous complaints were also expressed as to the large quantity of smoke produced by the plant working the dynamos. A long discussion arose on these two questions raised by MM. Binder and Duplan. The solution, however, as was indicated by M. Lépine, Secretary-General of the Prefecture of Police, did not lie within the jurisdiction of the administration. Still, in order to elucidate the duties of the city authorities in regard to the concessionary companies, the council, on the proposition of M. Ferdinand Duval, invited the Prefect of the Seine, to publish the contracts entered into by the city authorities with the Popp Company for the transmission of power, and with the electric lighting companies. A resolution, proposed and seconded by MM. Stupuy and Morane, was then ordered to be sent to the administration, inviting it to make experi-

ments and trials in order to find a good smoke-consuming apparatus.

We take the following, on the above subject from *Le Soleil*, which it prints under the heading of "The Popp Company":—"The accident which occurred in the cellars of the Grand Café was again spoken of. M. Maurice Binder wished to know the results of the inquiry made by the Prefecture of Police. The Secretary-General of the Prefecture stated that the Popp Company had installed, on its own account, in the cellars of the Grand Café, batteries of accumulators which were used for the feeding of about 1,400 lamps. The accumulators became too highly charged, the apparatus worked badly, which caused an explosion and fire. And it appeared that the same cause had already caused similar effects on several previous occasions, which is the best proof that the surveillance of electrical stations is quite insufficient."

ILLUMINATION BY ARTIFICIAL LIGHTS.

By S. ALFRED VARLEY.

THE report of Sir C. G. Stokes, Lord Rayleigh, and Sir William Thomson, on the respective penetrating powers of oil lights, gas lights, and the electric light through hazy sea atmospheres, has been briefly noticed in the ELECTRICAL REVIEW of October 31st, 1890. The conclusion which was arrived at by the above-named distinguished physicists as the result of carefully-conducted observations is, that the electric light, as exhibited at the South Foreland, has greater penetrating power than the light produced from burning oil or gas.

The purpose of this article is not to criticise in any way the efficiency of the electric light for lighthouse purposes, but to direct attention to certain matters bearing on the subject of general illumination. The object of all artificial illumination is to enable us to see in the absence of sunlight, but the part played by our optical organ seems to the writer to have been very generally overlooked in public discussions on the efficiency of the different systems of artificial illumination.

The amount of light which the earth receives at any given spot is much greater in the summer than in the winter; the light at mid-day is also greater than, say, an hour before sunset; but we nevertheless see practically as well on a bright winter's day as we do in the summer, and we see in the afternoon of a summer's day equally as well as we do at mid-day, the reason being that the pupil of the eye automatically adjusts itself to the amount of light received.

Now, when arc lights are employed for the purpose of general illumination, the brilliancy of the light causes the pupil of the eye to contract, and consequently their actual efficiency is really very much less than that indicated by a photometer.

It would be very interesting if a series of experiments were carried out to determine the penetrating power of quantity, as distinguished from the quality of the light.

The oldest living electrician, as long as he can remember, has been familiar with the terms, quantity, and intensity as applied to electricity, and he has clearly grasped the relationship of the one to the other in electrical phenomena; but the same can scarcely be said of the influence which the quantity of matter in a state of combustion has on the penetrating power of luminous rays through the atmosphere, apart from the actual intensity of the combustion itself.

The penetrating capabilities of a large quantity of burning matter of low intensity were forcibly brought home to the writer in his daily journeys as a schoolboy over Blackfriars Bridge. He was so much impressed with the apparent brilliancy of the lights on the coal-lighters as seen from the bridge on a winter's evening, that he went down to the river bank to ascertain their source, and to his great surprise he found what appeared to be

\* Comptes Rendus de l'Académie des Sciences.  
† Recherches de Thermo-Electricité (Comptes Rendus, Vol. cxi., p. 477, 1890).  
‡ Experiments made at the Physics Laboratory of the Higher Ecole Normale.

very brilliant lights when viewed from a distance were only smoky coal fires burning in iron baskets.

The apparent brightness of open coal fires, when viewed from a distance in a dark night, is undoubtedly in no small degree to be attributed to the behaviour of the optical organ itself. The pupil of the eye under such circumstances is very fully dilated, and consequently receives a large pencil of rays, and these rays being of low intensity, they do not irritate the eye and cause the pupil to contract. Now, it is within our experience that a large number of rays of low intensity entering the eye produces a similar effect on the retina, as a smaller number of light rays of higher intensity, and if the fact be taken into consideration that luminous rays of low refrangibility, such as those which a coal fire burning in the open air produces in abundance, are not nearly so much obstructed as rays of light of higher refrangibility (especially when the atmosphere is hazy), then the apparent superior brilliancy to the eye of a coal fire as seen from a distance over that of a gas flame, or even an electric light, is easily accounted for.

The writer well remembers his attention being directed to a very brilliant light in the distance in the middle of a high road, which impressed the eye as being very much more brilliant than the gas lamps, and he found the light proceeded from the turnpike man's fire-grate, an ordinary coal fire, which was not a very brilliant one.

In the year 1860, or thereabouts, a company, actively promoted by the late Sir Charles Bright, was formed for lighting the streets, buildings, &c., with the oxyhydrogen limelight, and the company lighted for a short time, experimentally, old Westminster bridge. So far as general illumination was concerned, the system proved to be a complete failure, the impression produced being that the bridge was dotted with a number of bright and pretty stars, but that the illumination of the bridge was being effected by the ordinary gas lights.

In the year 1874, speaking from memory, the late Robert Sabine, Mr. Gatehouse, and the writer were experimenting at the British Telegraph Company's works with a Gramme machine of the—at that time—largest size manufactured. The electric lamp was in a glass room on the top of the building looking towards the south, and the day was fine, but the sky was covered with light clouds through which the sun shone.

We had a long wedge of semi-opaque neutral tinted glass for looking at the arc with, the surfaces of the wedge were ground flat and polished, the thinner end being a knife-edge and the thicker end being about half-an-inch thick. When looking through the wedge at about two inches from the thinner end the electric light was just visible to the eye, and a little higher up it became wholly obscured. Now the writer found to his surprise that when he looked at the sun through this wedge the sun could be seen through a considerably greater thickness of the semi-opaque glass than the electric light was capable of penetrating. It occurred to him afterwards that the wedge was possibly largely composed of opaque matter, and that the light passed through what was practically a number of fine pin holes, and that, as when looking at the arc, the glass wedge was not more than 7 or 8 inches from it, the greater percentage of the rays struck the glass at an angle and passed consequently through a greater thickness than they would have done if the rays had been parallel as was the case when looking at the sun. At the same time, it seems somewhat remarkable that the sun's rays after passing through 95,000,000 miles of space, and then through clouds and our atmosphere, should have greater power to penetrate semi-opaque matter than an electric arc light which was only a few inches from the glass wedge.

Everyone who has witnessed a great fire must have been impressed with its powers to illuminate. The writer had the good fortune to see the great fire which occurred in Tooley Street, now, a good many years ago. The dome of St. Paul's, the Monument, and the buildings on the Middlesex side of the river were lighted up magnificently, owing to the quantity of light as distinguished from the intensity of the combustion.

Now the writer would very much like to see syste-

matic experiments carried out to ascertain the respective penetrating powers of coal fires, gas lights, and the electric light through hazy atmospheres, and he would not be surprised if the results obtained from such experiments went to show that, under special conditions, it would be more economical for the purpose of illuminating distant objects, for a given amount of coal to be burned in an open fire grate than to burn a similar quantity in a steam engine, and from the energy developed, produce an electric light.

## ELECTRICITY METERS.\*

By ROBERT SHAND.

BEFORE proceeding to consider the subject of this paper, it may be interesting to glance briefly at the developments which have secured for electricity meters the wide attention they receive, and which have made them important factors in the success of any general system of electrical distribution.

When the incandescent lamp was first introduced to an expectant public, people were quick to recognise its many merits and advantages, and the more consideration they gave the new illuminant, the more apparent became its vast superiority to all other illuminants in use for purposes of interior illumination. It was cleanly, and produced comparatively little heat, the atmosphere was not robbed of oxygen and vitiated with combustion products, as was the case where gas or oil flames were employed, and it could be used in many places where gas or oil would be unsafe. It was perfectly understood, however, by those interested in the development of the new illuminant, that however much it might be admired, however desirable it might appear, its progress into general use would be determined principally by its price. If it cost more than people were accustomed to pay for their light, they would continue the use of the elderly, smoky article, and await the development—that is, the cheapening of the new and cleanly method of lighting. The expense and difficulty attendant on the maintenance of small isolated installations, involving the use of steam, gas, or other engines, dynamos, &c., was such as but few people could afford to incur; so that as long as this presented the only means whereby the benefits of the new illuminant could be secured, it must remain a luxury, the desired development could not be effected, and its progress into use must necessarily be extremely slow and unsatisfactory.

Consideration, then, of the practical requirements for the supply of small consumers, suggested the construction of central stations where electric energy could be generated on a large scale, and which could be fitted with a wide-spreading system of conductors in such a manner, that people so desiring, could have stores, houses, &c., within the area of distribution fitted up, and electric energy placed at their disposal in a manner analogous to that followed by gas and water companies in their supply systems. The construction of central stations promised cheap distribution, and as, at that time, cheap production of electric energy by means of dynamo-electric machines was already an accomplished fact, it was assumed quite generally that electrical energy would almost immediately become available to small consumers; but unfortunately many obstacles, then unforeseen, acted to postpone the realisation of these sanguine hopes.

Towards the end of the year 1886 it was estimated that the total number of incandescent lamps in use in the United States was only about one-half million, all practically supplied on the two and three-wire, low tension, direct system. Then came the development of the high tension parallel system of distribution employing alternating currents and transformers. Many local companies engaged in arc lighting saw the opportunity afforded them to supply incandescent lamps also, and quickly took their places in the new field of

\* New York Electrical World.

enterprise thus opened. They realised that by using this transformer system many of the obstacles that prevented the growth of incandescent lighting on the low tension direct system, in other than districts closely built, were materially reduced. Numerous new companies were organised that made more or less a speciality of the alternating current system. Their activity reacted on those engaged in the development of direct current supply systems, spurring them to renewed and greater efforts than before, with the result that at the present time a conservative estimate places the number of incandescent lamps in use in the United States at over three millions, of which number probably one-third are supplied on the alternating current system. This development still continues, and its progress is so rapid that one cannot be said to risk much in expressing the belief that we are now on the highway toward the realisation of the condition of things eagerly anticipated and hoped for when central station construction was commenced; that is, a distribution of electric energy so cheap and so generally available that all who wish may become consumers and secure its benefits, the one necessary condition being that they agree to pay the exact value of the energy consumed, no more, no less.

This brings us at once to the question, On what depends the value of the electric energy consumed? This question must be answered before we can begin to devise methods of determining the "value received" which it is necessary to know before presenting the consumer with the record of his extravagance—his bill.

The value of the supply depends upon its volume or quantity and the electromotive force or pressure at which it is delivered. The product of the current in amperes by the electromotive force in volts gives the rate of the supply, that is, the power at any time in volt amperes, or watts. The total consumption, therefore, is represented by the product,

$$\begin{aligned} &\text{volts} \times \text{amperes} \times \text{time} \\ &\text{or volts} \times \text{coulombs.} \end{aligned}$$

For example: if we suppose two incandescent lamps in use, each taking one ampere of current at 50 volts potential, electric energy is then being converted into heat in the lamps at the rate of 100 watts per second. Assuming the current and the pressure to remain constant for one hour, the energy converted into heat in the lamps during that hour will equal 100 watts for 3,600 seconds, or 360,000 watt seconds or joules. In practice this quantity would probably be expressed at 100 watt hours. It might also be expressed as 265,000 foot-pounds, or .134 horse-power hours. When an ampere hour is spoken of, the electromotive force or pressure is disregarded, and an expression adopted which it is sometimes convenient to use, what is really meant being a supply of 3,600 coulombs of quantity of electricity. This supply may be delivered in a second, or in an hour, or any measurable interval of time may be taken in its delivery, but so long as the product of the current strength in amperes by the time during which it was supplied equals 3,600, it may be expressed as an ampere hour.

For the measurement of any particular time of the electrical quantities we are considering, numerous beautiful and accurate instruments are available, but these evidently cannot comply with the conditions for ascertaining the value of a supply, extending, it may be, over a month or longer, the reason of this being that they are not furnished with means of constant following and registering its successive progressions. In order to know the value of a consumer's supply with certainty and completeness, an instrument must be provided capable of measuring the two factors of the supply—quantity and pressure—and also capable of making a continuous and cumulative record of the supply as it proceeds. An instrument capable of doing this is called a watt-hour meter, energy meter, or erg meter. When, however, it is considered permissible that the pressure factor be accepted as a constant by which the ampere seconds or coulombs recorded may

be multiplied and the product accepted as representing the energy consumed, then the instruments capable of doing this, of recording ampere seconds or coulombs, are called coulomb meters.

In any parallel system of supply the maintenance of constant potential at all points of supply is the characteristic and most important feature, and, where it is maintained, coulomb meters may do the work satisfactorily, but where the potential fluctuates between limits not necessarily wide, energy meters would appear to be desirable.

In forming an opinion regarding the relative merits of coulomb and energy meters, it must be remembered that what the consumer pays for is energy, and if the potential factor of his supply is allowed to fall, the result will probably be a much greater fall in the efficiency of his supply, whether light or power called for at the point of consumption. It would certainly appear, therefore, that the most scientific instrument, the energy meter, ought also to be the most satisfactory in use, inasmuch as it most nearly measures that which the consumer really pays for. If electrical energy was a material substance, a rarefied combustible, for instance, like its would-be rival, gas, it would then be sufficient that the coulomb-meter measure its volume, temperature and pressure being constant, in order to know the amount of consumption. Electricity, however, cannot be measured by the cubic foot like gas, and since it cannot be measured directly at all, some of the effects produced in the conductor, or in the neighbourhood of the conductor, must be measured; in other words, it must be made to do work of some kind, and the relation existing between the amount of work done and the electric energy necessary to do it having been determined, the one becomes the measure of the other.

The effects, then, which electricity is capable of producing are three in number, viz., chemical, magnetic, and heating, and these three effects or properties mark three lines along which inventors have laboured in the production of electricity meters.

The first of these properties, the chemical, has been extensively applied ever since its laws were discovered by Faraday. When a current of electricity passes through an electrolytic cell containing the salt of a metal in solution, it carries metal with it to the cathode (i.e., the plate by which it leaves the liquid), and deposits it there. The weight of metal thus deposited is proportional to the number of coulombs that have passed through the cell, and, in order to determine the number, it is sufficient that one of the plates be removed from the cell, weighed, and the difference in weight, the amount it has gained or lost, divided by the number representing the weight of metal which an ampere in a second would deposit from the solution contained in the cell.

This method is so beautifully simple, and so easily applied in any direct system of supply, that a superficial view would suggest its immediate adoption. If we study the method closely, however, with the view of applying it to our purpose, we find in the electrolytic cell inherent weaknesses which are apt to become quite important sources of error when the cell is left to itself for any considerable length of time. Non-uniformity in density of solution employed, foreign substances present in the material of the plates, variations of temperature, are some of the causes interfering with the reliability of the method. If we consider, also, that the consumer is unable to inform himself regarding the progress of his supply by inspecting his meter, and the necessity which exists for taking the meter apart in order to discover it, we will probably concede the possession by the electrolytic cell of many features undesirable in a meter.

The magnetic property of the electric current is apparently the one of which the greatest number of inventors have availed themselves, and which they have applied in the construction of meters. Often, when this method is applied, the meter takes the form of an electric motor having a revolving armature and fitted with some brake device which absorbs the work of the

motor in such a way as to make its rate of movement proportional to the current strength. For example, if the force acting on the armature is proportional to the square of the current, in order that the motor may rotate with twice the velocity when the strength of the current is doubled, it is necessary that the square of the rotations measure the brake force against which the motor is doing work; then the square of the number of rotations in a given time is a measure of the square of the electric current. Therefore, the rate of rotation measures the strength of the current and the number of rotations its quantity.

A form of electric motor, in the adaptation of which to use as an electricity meter, much thought and labour has been expended by inventors, is that depending for its action on the electro-magnetic rotation of mercury. When mercury (or other conductor) is traversed by radial currents (*i.e.*, currents which enter at the centre and leave at the outside, or *vice versa*) and is at the same time acted upon by a magnetic field, the lines of induction in which act in a direction perpendicular to the surface of the mercury, it will rotate in a direction perpendicular to the lines of force and to the direction of flow of the current. Reversing the field changes the direction of rotation, but if at the same time the direction of flow of the current be changed, the direction of rotation will remain as before. The rotative force is said to vary as the square of the current, and the speed as the square root of rotative force. Liquid friction, therefore, in this case supplies the necessary controlling force. We see, therefore, that such a meter should be applicable to both systems of supply. With one notable exception, however (which will be mentioned later), inventors would seem to have met but scant measure of success in the adaptation of this form of motor meter.

In another application the meter takes the form of a machine driven by a constant force and controlled by a force which is also constant so long as no current passes through the conductor. Immediately when the current passes, however, the controlling force is modified, and the velocity of the machine accelerated by a quantity determined by and proportional to the rate of consumption. The acceleration thus becomes a measure of the consumption.

The heating effect of the electric current has received much attention, and many applications have been made of it to the work of electricity meterage since alternating current supply systems became prominent. When a current of electricity passes through a conductor, resistance is encountered and heat is generated, as shown by Joule, at a rate represented by the resistance multiplied by the square of the current. The heating effect being practically the same with alternating and with direct currents, its application seemed to promise a meter equally applicable in both systems of supply, which would approach the electrolytic method in its simplicity, and share at least one important advantage of the magnetic method, inasmuch as it might readily be made to register on dials. Numerous novel and beautiful applications of the heating property of an electric current have been made by Prof. Elihu Thomson to meters, giving their indications by the expansion of gases, by the evaporation, under special conditions, of various liquids, and in other ways.

The ordinary compound bar formed from two strips of material, generally metals possessing different coefficients of expansion and firmly attached to each other throughout their length, may also, in certain combinations, be applied to metering purposes. If one end of such a bar be fixed, and the other end left free to move under the influence of heat, the free end will be deflected through a distance which will be greater or less according as the heat producing the deflection is greater or less. If an inking stylus be attached to the free end of such a bar, and a cylinder or circular dial carrying a properly lined chart revolved at a constant speed in such relation to the bar that the stylus bears lightly against the surface of the chart, heat developed in the bar will cause it to be deflected and the stylus will trace a line on the chart at a greater or less distance from the

zero point, according as the flow of current heating the bar is greater or less. It is apparent, however, that an ordinary compound bar being a simple temperature-measuring device will have motions of its own, independent of the current effect, produced by variations of temperature in the surrounding atmosphere. Errors due to this cause must be avoided. Profs. Geyer and Bristol, in a meter invented by them and constructed on the above plan, avoid this source of error by substituting for the common bar its equivalent made from two pieces of the same material, to one of which is given a radiating surface very much greater than that possessed by the other one. These pieces are firmly secured together, but insulated from each other throughout the greater portion of their length, and are traversed in series by the current which it is desired to measure.

The meter of Prof. E. W. Rice is an integrating or recording meter, and in its construction the arrangement of the compound bars at once eliminates all danger of errors arising from changes of external temperature. In its arrangement two bars are used, which are secured a short distance apart, their free ends being yoked together. The construction of the bars is such that a very slight development of heat is sufficient to effect a considerable displacement of the free ends. Heat is developed in the bars alternately, one only being in the circuit at any time. A slow vibration of the bars results, and within certain limits the rate of vibration can be made to measure to a close approximation the rate of flow of current, which is registered on a common counter in the usual manner.

Another method is that applied by Prof. Forbes. The current to be measured is passed through a conductor placed under a glass or metal cover. When the conductor becomes heated, connection currents circulate in the air in which the conductor is immersed, and these currents are made to expend a portion of their energy in driving a mechanism which effects the registry.

We will now briefly consider a few of the meters which have met with more or less extensive application in practical work. A meter which has been much noticed of late is that known as the Aron meter. This meter is a development of the clock ergometer proposed by Profs. Ayrton and Perry many years ago. Its operation depends on the fact that, within certain limits, the rate of vibration of a pendulum increases with the square roots of the forces attracting it. In one form of this instrument a permanent steel magnet forms the pendulum bob, and immediately underneath, secured to the base of the instrument, is placed a coil of wire, through which the whole of the current to be measured is passed. In the meter case are placed two clock movements; one drives an ordinary pendulum, the other drives the pendulum carrying the magnet; the acceleration of the latter, due to increase of the attracting force acting on the magnet when current is passing in the coil is, by means of differential gearing connecting the two clock movements, indicated upon dials, which are read by the aid of a constant experimentally determined for each instrument. This arrangement constitutes a coulomb meter.

The arrangement originally proposed by Profs. Ayrton and Perry (who seem quite early to have recognised the importance of the meter question) was that of an energy meter, the pendulum bob being a fine wire coil of high resistance connected in shunt across the installation. The latest form of the Aron meter, one which is applicable to the meterage of both alternating and direct systems of supply, is constructed according to their method, the bob being a coil of thin wire attached to the end of the pendulum rod and encircled by the horizontally placed current coil. An interesting feature of this meter is the differential gearing. Two wheels, each about one and a quarter inches in diameter, and having two sets of teeth, being at once spur wheels and crown wheels, are placed about half an inch apart and driven in opposite directions on the same axis, one by each of the clocks. The cylindrical (or crown) gears are placed opposite each other, and a small planet wheel, free at the same time to turn on its own axis

and to roll around that of the cylindrical gears, is arranged between the latter, engaging both. Evidently if the velocity of the two wheels is equal and opposite, the planet wheel will simply be turned on its own centre, but if one of the wheels be driven at a greater velocity than the other, then the planet wheel will suffer a displacement, and will be carried round bodily in the direction and rotation of the wheel having the greater velocity, and this displacement being recorded indicates the consumption. When carefully placed in position, and delicately adjusted, this meter operates satisfactorily, and is sufficiently accurate. It is, however, large, and as yet costly, and it also requires that the clock springs be wound up about once a month.

The meter constructed by Prof. Forbes and introduced by him some two years ago is a beautiful instrument, sufficiently economical and capable of metering alternating and direct currents with equal accuracy. It would, therefore, seem to possess the qualities necessary to secure it a wide application in practical work. It does not appear, however, to have been applied to any extent in the United States. This meter depends for its action on the air currents created by the heat developed in a spirally arranged conductor attached to the base of the instrument; the resistance is said to be about one-hundredth of an ohm. Pivoted above this conductor is a light paper cone having a small pinion attached at the apex and a ring of thin mica at the base. Around the periphery of this ring are fixed eight small cylinders of pith, each carrying a light mica vane inclined at an angle of about 45 degrees to the mica ring. Inside the pinion at the top is a ruby jewel, which rests on a needle point supported upon and rising from the base of the instrument. When current passes through the conductor the convection currents rising impinge on the vanes and cause the cone to revolve (at a rate which Prof. Forbes succeeded in making almost exactly proportional to the current passing through the conductor) and to drive the counter which registers the number of revolutions. The revolving part of this meter is exceedingly light, and when the recording train is carefully constructed, the friction, it is claimed, is relatively small, even when the current is only one-twentieth of the meter's rated capacity. This instrument, is, of course, a quantity or coulomb meter.

The meter of Mr. Shallenberger is essentially an alternating current quantity, or coulomb meter. The construction of the meter is about as follows:

A coil of copper wire of oblong shape, placed horizontally, and traversed by the whole of the current to be measured, constitutes what may be called a primary or inducing circuit. Secured in the interior of this coil are a number of bare copper punchings, which, together, form a closed secondary circuit, and become the seat of induced currents. The planes of the primary and secondary coils cross each other at an angle of about 45 degrees. Inside the secondary closed coil, and closely embraced by it, is a thin ring of soft iron, secured on a light steel shaft, which is pivoted vertically, and free to rotate. The pulses of current, alternating in direction, and flowing through the outer coil to the lamps, induce secondary currents in the closed conductor, and also at the same time polarise the iron ring. Assuming these poles to be formed along the magnetic axis of the coil creating them, they will immediately be attracted toward the field of the closed secondary circuit, situated at an angular distance of about 45 degrees. Thus the pivoted iron being free to rotate, a motive force is created, which is within the range of the instrument approximately proportional to the square of the current. The controlling force in this meter is afforded by air friction, which opposes the motion of a four-winged fan, secured to the shaft carrying the iron ring. It is evident the indications of this meter must be affected by barometric and temperature changes, and also, to some small degree, by changes in the rate of alternations. The former effect would probably be specially noticeable if meters calibrated at sea level were used at varying heights above sea level. These

meters are made of 20 and 40 ampère capacity, and a large number are said to be in use.

The meter of Mr. Ferranti, though almost unknown in the United States, is said to be extensively employed in England in connection with the supply system of that inventor. This is a kind of motor meter, having a magnetic circuit which suggests that of Dr. Hopkinson's Manchester dynamo, the top pole piece, however, being prolonged downward, and wound with a few turns of copper conductor, around which the current is led to the mercury, which it traverses radially. The mercury being placed in a gap in the magnetic circuit, and crossed by lines of force, rotates, carrying a small paddle around with it. A small pinion fixed on a slender shaft rising from the paddle, drives a carefully jewelled train of wheel-work which registers the revolutions. Long range is one of the points aimed at in this meter, and the iron used in its construction (which is laminated) being necessarily but slightly magnetised, the driving force developed by small currents is feeble, thus making the internal friction of the machine relatively important.

Prof. Elihu Thomson early realised the importance assumed by internal friction in meters dynamical in their action, and devised a method by which errors due to it could be made vanishingly small without making extreme delicacy of construction necessary; this he accomplished by supplying to the meter subsidiary energy by means of a shunt or special winding, for instance, sufficient to create a force equal to that opposed by friction and inertia. Since that time the method has been applied by others. Mr. Ferranti winds on his meter magnet a high resistance shunt coil in addition to the conductor carrying the current measured. Arranged in this way a 50-ampère meter is said to start with less than one ampère, a range and a delicacy which are certainly remarkable in an instrument of its class.

An exceedingly interesting application of the electrolytic method to the metering of alternating currents has been made by the English firm of Lowrie, Hall and Co. In applying their method the inventors include in the secondary circuit of the transformer an electrolytic cell containing a saturated solution of copper sulphate in distilled water. The copper plates employed in the cell expose a surface of four square inches per ampère with maximum load. In the same box with the deposition cell is placed an accumulator cell, and the entire current supplied to the lamps is passed through these two cells in series. The effect of this arrangement is to introduce an electromotive force of constant direction into the circuit which adds itself to the alternating electromotive force during the half period when it is in the same direction, and subtracts itself during the half period when it is in the opposite direction. If, for instance, the alternating electromotive force equals 100 volts, and the constant electromotive force of the accumulator cell is two volts, then in the one direction there is acting an electromotive force of 102 volts, and in the other direction, an electromotive force of 98 volts. The volume of current, therefore, flowing in one direction during a half period is greater than that flowing during the other half period by a quantity equal to four volts divided by a resistance which is determined by the number of lamps in circuit. This quantity of current is available, therefore, to make a record in an electrolytic cell. This system does not suggest itself as a very practical one, but is, however, exceedingly interesting from the fact of its being the only application of the electrolytic method to the commercial meterage of alternating currents.

In this article it has merely been attempted to describe a few types of meter in common use. A very large number, however, have been invented and from time to time introduced. Reference, however, to the work of each inventor is more than can be attempted in any single article on the subject. And still the work goes on, no existing electricity meter satisfying all requirements so fully as to render its use completely satisfactory.

## THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.

(Continued from page 650.)

## ELECTRO-MAGNETS FOR MAXIMUM TRACTION.

These have already been dealt with in the preceding lecture; the characteristic feature of all the forms suitable for traction being the compact magnetic circuit.

Several times it has been proposed to increase the power of electro-magnets by constructing them with intermediate masses of iron between the central core and the outside, between the layers of windings. All these constructions are founded on fallacies. Such iron is far better placed either right inside the coils or right outside them, so that it may properly constitute a part of the magnetic circuit. The constructions known as Camacho's and Cance's, and one patented by Mr. S. A. Varley in 1877, belonging to this delusive order of ideas, are now entirely obsolete.

Another construction which is periodically brought forward as a novelty is the use of iron windings of wire or strip in place of copper winding. The lower electric conductivity of iron, as compared with copper, makes such a construction wasteful of exciting power. To apply equal magnetising power by means of an iron coil implies the expenditure of about six times as many watts as need be expended if the coil is of copper.

## ELECTRO-MAGNETS FOR MAXIMUM RANGE OF ATTRACTION.

We have already laid down the principle which will enable us to design electro-magnets to act at a distance. We want our magnet to project, as it were, its force across the greatest length of air gap. Clearly, then, such a magnet must have a very large magnetising power, with many ampère turns upon it, to be able to make the required number of magnetic lines pass across the air resistance. Also it is clear that the poles must not be too close together for its work, otherwise the magnetic lines at one pole will be likely to curl round and take short cuts to the other pole. There must be a wider width between the poles than is desirable in electro-magnets for traction.

## ELECTRO-MAGNETS OF MINIMUM WEIGHT.

In designing an apparatus to put on board a boat or a balloon, where weight is a consideration of primary importance, there is again a difference. There are three things that come into play—iron, copper, and electric current. The current weighs nothing, therefore, if you are going to sacrifice everything else to weight, you may have comparatively little iron, but you must have enough copper to be able to carry the electric current; and under such circumstances you must not mind heating your wires nearly red hot to pass the biggest possible current. Provide as little copper as you conveniently can, sacrificing economy in that case to the attainment of your object; but of course you must use fire-proof material, such as asbestos, for insulating, instead of cotton or silk.

## A USEFUL GUIDING PRINCIPLE.

In all cases of design there is one leading principle which will be found of great assistance, namely, that a magnet always tends so to act as though it tried to diminish the length of its magnetic circuit. It tries to grow more compact. This is the reverse of that which holds good with an electric current. The electric circuit always tries to enlarge itself, so as to enclose as much space as possible, but the magnetic circuit always tries to make itself as compact as possible. Armatures are drawn in, as near as can be, to close up the magnetic circuit. Many two-pole electro-magnets show a tendency to bend together when the current is turned on. One form in particular, which was devised by Ruhmkorff for the purpose of repeating Faraday's celebrated experiment on the magnetic rotation of polarized light, is liable to this defect. Indeed, this form of electro-magnet is often designed very badly, the yoke being too thin, both mechanically and magnetically, for the purpose which it has to fulfil.

Here is a small electric bell, constructed by Wagener of Wiesbaden, the construction of which illustrates this principle. The electro-magnet, a horseshoe, lies horizontally; its poles are provided with protruding curved pins of brass. Through the armature are drilled two holes, so that it can be hung upon the two brass pins; and when so hung up it touches the ends of the iron cores just at edge, being held from more perfect contact by a spring. There is no complete gap, therefore, in the magnetic circuit. When the current comes and applies a magnetizing power it finds the magnetic circuit already complete in the sense that there are no absolute gaps. But the circuit can be bettered by tilting the armature to bring it flat against the polar ends, that being indeed the mode of motion. This is a most reliable and sensitive pattern of bell.

*Electro-magnetic Pop-gun.*—Here is another curious illustration of the tendency to complete the magnetic circuit. Here is a tubular electro-magnet (fig. 53), consisting of a small bobbin, the core of which is an iron tube about two inches long. There is nothing very unusual about it; it will stick on, as you see, to pieces of iron when the current is turned on. It clearly is an

ordinary electro-magnet in that respect. Now suppose I take a little round rod of iron, about an inch long, and put it into the end of the tube, what will happen when I turn on my current? In this apparatus as it stands, the magnetic circuit consists of a short length of iron, and then all the rest is air. The magnetic circuit will try to complete itself, not by shortening the iron, but by lengthening it; by pushing the piece of iron out so as to afford more surface for leakage. That is exactly what happens; for, as you see, when I turn on the current the little piece of iron shoots out and drops down. You see that little piece of iron shoot out with considerable force. It becomes a sort of magnetic pop-gun. This is an experiment which has been twice discovered. I found it first described by Count Du Moncel, in the pages of *La Lumière Electrique*, under the name of the "pistolet électromagnétique;" and Mr. Shelford Bidwell invented it independently. I am indebted to him for the use of this apparatus. He gave an account of it to the Physical Society, in 1885, but the reporter missed it. I suppose, as there is no record in the Society's proceedings.

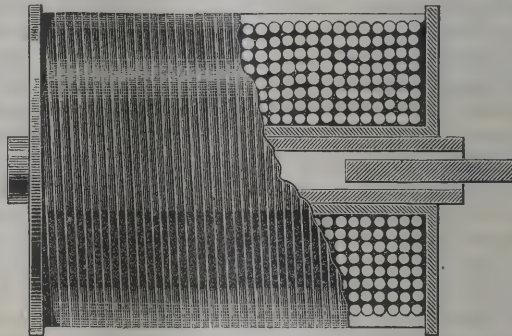

FIG. 53.—ELECTRO-MAGNETIC POP-GUN.

## ELECTRO-MAGNETS FOR USE WITH ALTERNATING CURRENTS.

When you are designing electro-magnets for use with alternating currents, it is necessary to make a change in one respect, namely, you must so laminate the iron that internally eddy currents shall not occur; indeed, for all rapid acting electro-magnetic apparatus it is a good rule that the iron must not be solid. It is not usual with telegraphic instruments to laminate them by making up the core of bundles of iron plates or wires, but they are often made with tubular cores, that is to say, the cylindrical iron core is drilled with a hole down the middle, and the tube so formed is slit with a saw-cut to prevent the circulation of currents in the stance of the tube. Now when electro-magnets are to be employed with rapidly alternating currents, such as are used for electric lighting, the frequency of the alternations being usually about 100 periods per second, slitting the cores is insufficient to guard against eddy-currents; nothing short of completely laminating the cores is a satisfactory remedy. I have here, thanks to the Brush Electric Engineering Company, an electro-magnet of the special form that is used in the Brush arc lamp when required for the purpose of working in an alternating current circuit. It has two bobbins that are screwed up against the top of an iron box at the head of the lamp. The iron slab serves as a kind of yoke to carry the magnetism across the top. There are no fixed cores in the bobbins, which are entered by the ends of a pair of yoked plungers. Now in the ordinary brush lamp for use with a steady current, the plungers are simply two round pieces of iron tapped into a common yoke; but for alternate current working this construction must not be used, and instead a U-shaped double plunger is used, made up of laminated iron, riveted together. Of course it is no novelty to use a laminated core; that device, first used by Joule, and then by Cowper, has been re-patented rather too often during the past fifty years to be considered as a recent invention.

The alternate rapid reversals of the magnetism in the magnetic field of an electro-magnet, when excited by alternating electric currents, sets up eddy-currents in every piece of undivided metal within range. All frames, bobbin tubes, bobbin ends, and the like, must be most carefully slit, otherwise they will overheat. If a domestic flat-iron is placed on the top of the poles of a properly laminated electro-magnet, supplied with alternating currents, the flat-iron is speedily heated up by the eddy-currents that are generated internally within it. The eddy-currents set up by induction in neighbouring masses of metal, especially in good conducting metals such as copper, give rise to many curious phenomena. For example, a copper disc or copper ring placed over the pole of a straight electro-magnet so excited is violently repelled. These remarkable phenomena have been recently investigated by Professor Elihu Thomson, with whose beautiful and elaborate researches we have lately been made conversant in the pages of the technical journals. He rightly attributes many of the repulsion phenomena to the lag in phase of the alternating currents thus induced in the conducting metal. The electro-magnetic inertia, or self-inductive property of the electric circuit, causes the currents to rise and fall later in time than the electromotive forces by which they are occasioned. In all such cases the impedance which the circuit offers is made up of two things—resistance and inductance. Both these causes tend to diminish the amount of current that flows, and the inductance also tends to delay the flow.

\* Cantor Lecture. Delivered before the Society of Arts, February 3rd, 1890.

## ELECTRO-MAGNETS FOR QUICKEST ACTION.

I have already mentioned Hughes's researches on the form of electro-magnet best adapted for rapid signalling. I have also incidentally mentioned the fact that where rapidly varying currents are employed, the strength of the electric current that a given battery can yield is determined not so much by the resistance of the electric circuit, as by its electric inertia. It is not a very easy task to explain precisely what happens to an electric circuit when the current is turned on suddenly. The current does not suddenly rise to its full value, being retarded by inertia. The ordinary law of Ohm in its simple form no longer applies; one needs to apply that other law which bears the name of the law of Helmholtz, the use of which is to give us an expression, not for the final value of the current, but for its value at any short time,  $t$ , after the current has been turned on. The strength of the current after a lapse of a short time,  $t$ , cannot be calculated by the simple process of taking the electromotive force and dividing it by the resistance, as you would calculate steady currents.

In symbols, Helmholtz's law is:—

$$i_t = \frac{E}{R} \left( 1 - e^{-\frac{R}{L}t} \right).$$

In this formula  $i_t$  means the strength of the current after the lapse of a short time  $t$ ;  $E$  is the electromotive force;  $R$  the resistance of the whole circuit;  $L$  its co-efficient of self-induction; and  $e$  the number 2.7183, which is the base of the Napierian logarithms. Let us look at this formula; in its general form it resembles Ohm's law, but with a new factor, namely, the expression contained within the brackets. This factor is necessarily a fractional quantity, for it consists of unity less a certain negative exponential, which we will presently further consider. If the factor within brackets is a quantity less than unity, that signifies that  $i_t$  will be less than  $E \div R$ . Now the exponential of negative sign, and with negative fractional index, is rather a troublesome thing to deal with in a popular lecture. Our best way is to calculate some values, and then plot it out as a curve. When once you have got it into the form of a curve, you can begin to think about it, for the curve gives you a mental picture of the facts that the long formula expresses in the abstract. Accordingly we will take the following case. Let  $E = 2$  volts;  $R = 1$  ohm; and let us take a relatively large self-induction, so as to exaggerate the effect; say let  $L = 10$  quads. This gives us the following:—

$t$ (sec.)	$e^{-\frac{R}{L}t}$	$i_t$
0	1	0
1	1.105	0.950
2	1.221	1.810
5	1.649	3.936
10	2.718	6.343
20	7.389	8.646
30	20.08	9.501
60	403.4	9.975
120	162800.0	9.999

In this case the value of the steady current, as calculated by Ohm's law, is 10 amperes; but Helmholtz's law shows us that with the great self-induction, which we have assumed to be present, the current, even at the end of 30 seconds, has only risen up to within 5 per cent. of its final value; and only at the end of two minutes has practically attained full strength. These values are set out in the highest curve in fig. 54, in which, however, the

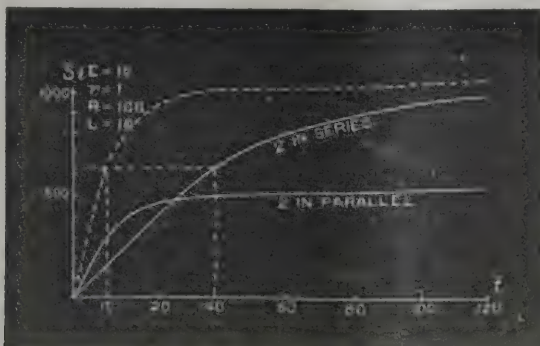

FIG. 54.—CURVES OF RISE OF CURRENTS.

further supposition is made that the number of spirals,  $s$ , in the coils of the electro-magnet is 100, so that when the current attains its full value of 10 amperes, the full magnetising power will be  $s i = 1,000$ . It will be noticed that the curve rises from zero at first steeply and nearly in a straight line, then bends over, and then becomes nearly straight again, as it gradually rises to its limiting value. The first part of the curve—that relating to the strength of the current after very small interval or time—is the period within which the strength of the

current is governed by inertia (*i.e.*, the self-induction) rather than by resistance. In reality the current is not governed either by the self-induction or by the resistance alone, but by the ratio of the two. This ratio is sometimes called the "time constant" of the circuit, for it represents the time which the current takes in that circuit to rise to a definite fraction of its final value. This

definite fraction is the fraction  $\frac{e-1}{e}$ ; or in decimals, 0.634. All

curves of rise of current are alike in general shape—they differ only in scale; that is to say, they differ only in the height to which they will ultimately rise, and in the time they will take to attain this fraction of their final value.

Example (1).—Suppose  $E = 10$ ;  $R = 200$  ohms;  $L = 8$ . The final value of the current will be 0.025 amp. or 25 milliamperes. Then the time constant will be  $8 \div 400 = \frac{1}{50}$ th sec.

Example (2).—The P.O. Standard "A" relay has  $R = 400$  ohms;  $L = 3.25$ . It works with 0.5 milliamperé current, and therefore will work with 5 Daniell cells through a line of 9,600 ohms. Under these circumstances the time constant of the instrument on short circuit is 0.0081 sec.

It will be noted that the time constant of a circuit can be reduced either by diminishing the self-induction or by increasing the resistance. In fig. 54 the position of the time constant for the top curve is shown by the vertical dotted line at 10 seconds. The current will take 10 seconds to rise to 0.634 of its final value. This retardation of the rise of current is simply due to the presence of coils and electro-magnets in the circuit; the current as it grows being retarded because it has to create magnetic fields in these coils, and so sets up opposing electromotive forces that prevent it from growing all at once to its full strength. Many electricians, unacquainted with Helmholtz's law, have been in the habit of accounting for this by saying that there is a lag in the iron of the electro-magnet cores. They tell you that an iron core cannot be magnetised suddenly; that it takes time to acquire its magnetism. They think it is one of the properties of iron. But we know that the only true time lag in the magnetisation of iron—that which is properly termed "viscous hysteresis"—does not amount to any great percentage of the whole amount of magnetisation, takes comparatively a long time to show itself, and cannot therefore be the cause of the retardation which we are considering. There are also electricians who will tell you that when magnetisation is suddenly evoked in an iron bar, there are induction currents set up in the iron which oppose and delay its magnetisation. That they oppose the magnetisation is perfectly true; but if you carefully laminate the iron so as to eliminate eddy currents, you will find, strangely enough, that the magnetism rises still more slowly to its final value. For by laminating the iron you have virtually increased the self-inductive action, and increased the time-constant of the circuit, so that the currents rise more slowly than before. The lag is not in the iron, but in the magnetising current, and the current being retarded, the magnetisation is, of course, retarded also.

## CONNECTING COILS FOR QUICKEST ACTION.

Now let us apply these most important, though rather intricate considerations to the practical problems of the quick working of the electro-magnet. Take the case of an electro-magnet forming some part of the receiving apparatus of a telegraph system, in which it is desired to secure very rapid working. Suppose the two coils that are wound upon the horseshoe core are connected together in series. The coefficient of self-induction for these two is four times as great as that of either separately; coefficients of self-induction being proportional to the square of the number of turns of wire that surround a given core. Now if the two coils, instead of being put in series, are put in parallel, the coefficient of self-induction will be reduced to the same value as if there were only one coil, because half the line current (which is practically unaltered) will go through each coil. Hence the time constant of the circuit when the coils are in parallel will be a quarter of that which it is when the coils are in series; on the other hand, for a given line current, the final magnetising power of the two coils in parallel is only half what it would be with the coil in series. The two lower curves in fig. 54 illustrate this, from which it is at once plain that the magnetising power for very brief currents is greater when the two coils are put in parallel with one another than when they are joined in series.

Now this circumstance has been known for some time to telegraph engineers. It has been patented several times over. It has formed the theme of scientific papers, which have been read both in France and in England. The explanation generally given of the advantage of uniting the coils in parallel is, I think, fallacious; namely that the "extra currents" (*i.e.*, currents due to self-induction), set up in the two coils are induced in such directions as tend to help one another when the coils are in series, and to neutralise one another when they are in parallel. It is a fallacy, because in neither case do they neutralise one another. Whichever way the current flows to make the magnetism, it is opposed in the coils while the current is rising, and helped in the coils while the current is falling, by the so-called extra currents. If the current is rising in both coils at the same moment, then whether the coils are in series or in parallel, the effect of self-induction is to retard the rise of the current. The advantage of parallel grouping is simply that it reduces the time-constant.

## BATTERY GROUPING FOR QUICKEST ACTION.

One may consider the question of grouping the battery cells from the same point of view. How does the need for rapid working, and the question of time-constant, affect the best mode of

grouping the battery cells? The amateur's rule, which tells you to so arrange your battery that its internal resistance should be equal to the external resistance, gives you a result wholly wrong for rapid working. The supposed best arrangement will not give you (at the expense even of economy) the best result that might be got out of the given number of cells. Let us take an example and calculate it out, and place the results graphically before our eyes in the form of curves. Suppose the line and electro-magnet have together a resistance of 6 ohms, and that we have 24 small Daniell's cells, each of electromotive force, say, 1 volt, and of internal resistance, 4 ohms. Also let the coefficient of self-induction of the electromagnet and circuit be 6 quadrants. When all the cells are in series the resistance of the battery will be 96 ohms, the total resistance of the circuit 102 ohms, and the full value of the current 0.235 ampère. When all the cells are in parallel the resistance of the battery will be 0.133 ohm, the total resistance 6.133 ohms, and the full value of the current 0.162 ampère. According to the amateur rule of grouping cells so that internal resistance equals external, we must arrange the cells in four parallels, each having six cells in series, so that the internal resistance of the battery will be six ohms, total resistance of circuit 12 ohms, full value of current 0.5 ampère. Now the corresponding time-constants of the circuit in the three cases (calculated by dividing the co-efficient of self-induction by the total resistance) will be respectively—in series, 0.06 sec.; in parallel, 0.5 sec.; grouped for maximum steady current, 0.96 sec. From these data we may now draw the three curves, as in fig. 55, wherein the abscissæ are

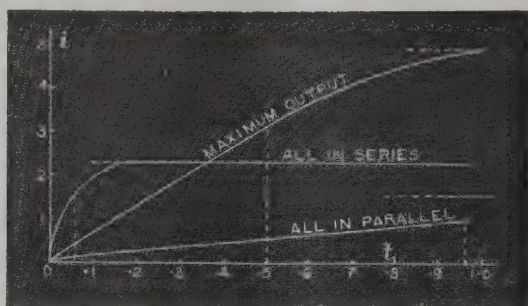

FIG. 55.—CURVES OF RISE OF CURRENT WITH DIFFERENT GROUPINGS OF BATTERY.

the values of time in seconds, and the ordinates the current. The faint vertical dotted lines mark the time-constants in the three cases. It will be seen that when rapid working is required the magnetising current will rise, during short intervals of time, more rapidly if all the cells are put in series than it will do if the cells are grouped according to the amateur rule.

When they are all put in series, so that the battery has a much greater resistance than the rest of the circuit, the current rises much more rapidly, because of the smallness of the time constant, although it never attains the same ultimate maximum as when grouped in the other way. That is to say, if there is self-induction as well as resistance in the circuit, the amateur rule does not tell you the best way of arranging the battery. There is another mode of regarding the matter which is helpful. Self-induction, while the current is growing, acts as if there were a sort of spurious addition to the resistance of the circuit; and while the current is dying away it acts of course in the other way, as if there were a subtraction from the resistance. Therefore you ought to arrange the battery so that the internal resistance is equal to the real resistance of the circuit, plus the spurious resistance during that time. But how much is the spurious resistance during that time? It is a resistance proportional to the time that has elapsed since the current was turned on. So then it comes to a question of the length of time for which you want to work it. What fraction of a second do you require your signal to be given in? What is the rate of the vibrator of your electric bell? Suppose you have settled that point, and that the short time during which the current is required to rise is called  $t$ ; then the apparent resistance at time after the current is turned on is given by the formula:—

$$R_t = R \times e^{\frac{R}{L}t} + \left( \frac{R}{L} - 1 \right).$$

(To be continued.)

## THE ELECTRIC LIGHT IN ITS RELATION TO THE CONSUMER.\*

By C. W. NAYLOR.

THE electric light is a broad subject for either study or discussion. It can be looked at from many directions. It is a theme for both the scientist and general student.

The mechanic or engineer who starts out intending to design

\* Read October 25th, before Illinois Branch No. 28, National Association of Stationary Engineers.

or build electric machinery and appliances, maps out for himself a life-long course of study. To the speculative business man who makes and sells the electric light as a commercial product, it has an intense interest. The investor in central station apparatus takes a peculiarly pecuniary view of the electric light.

Still another class finds itself compelled by circumstances to investigate the subject of electric lighting. This class is composed of the consumers. The consumer is forced to consider it. His reflections lead him rapidly to conclusions. It is a powerful and easily controlled means of illumination, capable of regulation at will, it can be extinguished or relighted at pleasure, and instantaneously; it can be moved and removed from place to place. It is, moreover, a safe light—safe in the insurance or fire risk sense. It is not so expensive that it can be classed among the luxuries. It must, perforce, be admitted that the electric light is a plain every day matter of fact illuminant, and, as a practical thing, has come to stay with us. As such, it is to be gauged and measured by that worldly standard—the almighty dollar.

The question is, "Does it pay?" The answer involves an intricate problem.

What does it cost to make the electric light? To anticipate somewhat, it will be found that it is proportionately cheaper to generate it on a large scale. This fact is not surprising, for it holds true in the operation of most commercial apparatus.

For very small generating plants, the costs as compared with those of medium-sized or large stations are utterly disproportionate. To operate a few lamps only, by means of machinery, would be many times more expensive than any of the other ordinary means of lighting.

It will not be necessary here to claim everything for the electric light and insist that it is a necessity, and that everybody must sooner or later adopt it. It will be only a matter of a few years at most when the claim will make itself good.

There is no necessity that the advocate of electric lights should lose his composure or worry over the seeming slowness of men to appreciate this great boon to the commercial world.

In a very short time—we shall live to see the day—the electric light will reign supreme where people live thickly congregated and depend for existence upon their industry. As present users enlarge their plants, as new converts augment the demand for it, production will be cheapened, and thereby its field of usefulness will be increased.

How much will it cost to put in and operate an electric light equipment?

Assume for the time being that there is no machinery in an establishment, and that it becomes necessary to rent lights, the place in question being a small store or salesroom. The charge for one arc lamp to burn all day, say for 10 hours, will be 50 cents per day. This can be compared with the price that would be paid for gas light. Assume as a basis of comparison 10 gas jets. This comparison, however, is hardly fair to the electric light, as the illumination given by the latter is vastly superior to that of the gas.

Ten gas jets at an average consumption of 5 cubic feet of gas per hour per burner, at \$1.25 per 1,000 feet will cost for 10 hours, 62½ cents. The electric light, as will be readily seen, is much the cheaper, is more powerful and penetrating, is cleaner, and vastly safer, so far as fire risk is concerned. It is switched on at once and off again just as quickly; it does not overheat the room: it will not ruin ceilings and walls with soot and grease, nor damage fabrics with deleterious, sulphurous and other gases. Gas cannot be obtained at a price much cheaper than that mentioned. Even at \$1 per 1,000, the cost figured as before will reach 50 cents per day, which is fully as expensive as the electric arc.

This is the limit of economy in gas lighting. Should it become desirable to light a large room or a number of rooms gas cannot be had cheaper. On the other hand, electric lights are rated by a graded price list. If 5, or 10, or 20 electric lights are needed, they are to be had for 40 cents each per day, which is 20 per cent. less than the charge for gas. In fact, they can be contracted for at the low rate of 33 cents per day, almost 40 per cent. cheaper than the gas method of lighting. Gas light varies with the season and output, now weak, now strong. Sometimes it can hardly be coaxed out of the burners, at other times it flames to the ceiling. Now it is yellow and now red; it is very often blue, but very seldom white. In winter so sluggish is it that it is with difficulty cajoled into leaving its natural lair under the ground.

The electric light assures to the consumer at all times the full measure of an almost perfect illumination. With all its drawbacks it is wonderfully superior to any and all other known means of artificial lighting. There are numerous objections to the use of this light, most of them, however, are trivial.

Considering it from the dollar and cents point, to which we shall endeavour to confine ourselves, there arises the apparently serious objection that the lights cost whether they are kept burning or not. Gas can be turned on or off, and a saving thereby effected.

There are large commercial houses in this city with spacious and well stocked sales and display rooms that are kept for hours at a stretch in the deepest gloom. When a salesman leads a customer perspective or *bond fide* through the various departments, a boy or porter precedes him turning on the gas and turning it off behind him, as he passes with his buyer.

This is not exaggerated. It is a most ridiculous transaction and cannot possibly be economical. People who are compelled to do this would save money by renting a smaller store and lighting it up as it should be lighted.

All the business done by an establishment of the kind cited above could be transacted in one-fourth of the space at present occupied.

One thousand dollars saved in rent and expended for electric lights or gas would make it possible to do a much larger business, and leave what is very desirable—a good impression on the trade.

To be consistent and follow out the line of policy exhibited in their scheme of lighting the store, these firms should dispense with their engineers and elevators and hire two or three strong labourers, who by patient industry might manage to carry, piece by piece, all their freight up and down stairs, day by day.

The electric light must be used in quantities to be really appreciated. A large business, however, cannot very well get along without it. Experience demonstrates the fact.

Among the firms in this city are scores that pay \$25 or more for this means of lighting. Several expend upward of \$40 or \$50 per day, while one house expends not less than \$100 hard cash each and every week day during the year for electric lights, and is not yet satisfied, but cries for more. It is not used as an advertisement. It is not a luxury, but a practical everyday attachment to the machinery of the establishment.

It will pay, and pay well. It does pay, and is paying. Use electric lights then, even if they must perforce be rented; but they are a much more profitable investment where the machines for generating the current are operated by the persons who are to use them.

The two principal items of expense going to make up the total cost of electric arc lights are fuel and labour. These two items constitute from 75 per cent. to 90 per cent. of all expense connected therewith. The cost of labour, which alone may amount to 50 per cent., 60 per cent., or even 80 per cent., of the total expense is the great stumbling-block in the way of operating a small plant. It is the only thing that requires special consideration when it has been decided to erect an outfit for operating fewer than 20 or 30 lights—of course circumstances have everything to do with the case and must be taken into account. For instance, a firm may have an engineer and a boy or young man with but little to do. These two together could operate a plant of 10, 20, or 30 lights at a minimum cost. The cost, possibly, would be as low as 12 cents or 15 cents per day per lamp, provided, of course, the time of neither the engineer nor the boy was charged to the expense of maintaining the lights. On the other hand, if an establishment has no engineer, no boilers, and no engine, and provides them especially in order that it may operate a plant of 10 lights' capacity, each lamp may cost it 45 cents, 50 cents, or even 60 cents per day, and that for less than 10 hours' run. The cost may reach as high as 75 cents or \$1 for a full day of 10 hours.

These estimates have reference only to the ordinary arc lamp and do not apply at all to the incandescent lamp. The same engineer and assistant whose wages were included in the last estimate, could very easily run 40 or 50 lamps at a cost not to exceed 25 cents, or at most 30 cents daily per light. This last case assumes that the engineer and his assistant have nothing to do but run the lights, and that there are no elevators, no machinery, no heating to attend to. The engineer is assumed to receive \$3 per day and the assistant \$1.50 cents per day. If more is paid for help or less, the running price per lamp will vary about 4 cents or 5 cents per day one way or the other, as the case may be.

The work put upon the operator of a plant of this kind running about 30 lights and not to exceed 40 lights, leaves considerable spare time on the hands of the engineer who can then, with the assistance of a fireman, take care of two or three elevators in addition to their duties as electricians. If so, and this is a very common case, and a fair proportion of their time be charged to elevators and heat, and the other legitimate departments of the regular engineer's work, then the cost of lighting is reduced just that much. The whole process is in harmony with the general proposition that an engineer can care for more machinery and elevators and fewer electric lights, or for a greater number of electric lights and fewer elevators and other machinery. As the proportion of each kind of work varies, so the cost per lamp for operating the electric light will oscillate between 22 or 23 cents as a minimum and 28 or 30 cents as a maximum.

It can be assumed as an axiom in electric lighting that it requires at least 1 horse-power's worth of fuel to operate an arc light. One horse-power may mean 2 lbs. of coal, or it may mean 10 lbs. In general practice it means from 4½ lbs. to 8 lbs. of fuel.

It will be contended that the former figure, 4½ lbs., or at most 5 lbs., is plenty large enough. Experience, however, will show that the coal bill at the end of the month, allowing for waste when starting, or banking fires, when the latter practice is followed, will tally best with a large or medium rate. We will figure, then, on a basis of 6 lbs. of coal, or its equivalent, if a different fuel is used.

Coal costs from \$1.50 to \$5.50 per ton, averaging between \$2.25 or \$2.50 and \$3.25, according to quantity and quality. Assume that it costs \$3 per ton of 2,000 lbs. A difference of 25 cents one way or the other from this price will not seriously affect the general result we are seeking. With 6 lbs. of coal per hour, the amount used in developing 1 horse-power or its equivalent, one arc light, will cost about nine-tenths of a cent per hour, or 8 cents to 9 cents daily for a 10 hours' run.

This estimate of 8 cents per day for fuel for each lamp is the basis upon which to build when estimating for electric lights. This item is fixed and unchangeable except in very small fractions. It is immaterial, practically speaking, whether the plant

is to have 30, 40, 50 or even 100 lamps. The coal consumption per lamp remains virtually constant.

Exclusive of labour all other expenses connected with the operation of an electric light plant can be readily compared with the cost of fuel to which it bears a nearly fixed ratio varying from one-fourth to one-half of the fuel cost, or from 2 to 4 cents, per day per lamp. The average is generally midway between these extremes, and approximating, therefore, to 3 cents daily. It appears now that arc lights are to cost for fuel and other expenses, exclusive of labour and carbons, the sum of 11 cents per day.

To the cost again must be another added fixed charge, that for carbons. Although important, this item is unvarying and to simplify the matter, has been left untouched until this late moment. It is even more rigid in its effect upon the price of lights than coal. Carbons, or carbon pencils, as they are called, do not vary in price over 10 per cent. between any two systems of lighting, nor does the amount consumed per lamp vary much more than 10 per cent. in the different systems, provided the running hours are the same, and a similar general economy is practiced.

Carbons are very cheap now. Six years ago they cost \$40 per 1,000; three years ago \$12 per 1,000; to-day even less than \$10 per 1,000. This great drop in price has effected a wonderful saving in the operation of electric lights.

Not less than one and one-half, and not more than three carbons per day per lamp are used. A very liberal estimate will allow for three carbons per lamp for the ten hours. If these carbons cost over a cent apiece, it is so little over that the fraction may be disregarded. Three cents a day is a very liberal allowance for this item of expense.

Add this to the 11 cents, and there is obtained a grand total of 14 cents per day per lamp as a measure of the operating expense attached to the generation and distribution of the electric arc lamps. It may be said that no risk will be incurred in accepting as accurate these figures of 8 cents for coal, 3 cents for incidentals, and 5 cents for carbons, and using them as standards.

In addition to these fixed values is the cost of labour, a most disturbing and widely varying element of wonderful importance, and demanding careful study. When it can be said that labour varies between one-half and nine-tenths of the total expense, it will be at once perceived how important a fact it is. Sometimes it is as low as one-half, or at least two-thirds of the established 14 cents, and, again, it is as high as five, six, or seven times that amount in proportion as the daily cost per light hovers between 22 cents per day and \$1 per day.

The cost we are now discussing is simply the operating expense connected with generating and distributing the light. No account is here taken of those other important elements which go to make up the total amount expended or tied up in the effort to furnish to the consumer this steady, constant, artificial means of illumination—interest on the plant, depreciation on machinery and buildings, rent, taxes, insurance, accidental expenses, collections, advertising and management, together make up an enormous total, not less in any case than 100 per cent. of the operating expenses, and very often more—so it will be seen that arc lights can not very well be profitably sold for much less than 40 cents per day, although they are furnished by contract for as low as 35 cents, or may be a shade less.

In several cases lights are run for this amount and less, but they cost more. If a small central station makes a practice of furnishing them for so small a sum as 30, 32, or 35 cents, it is simply throwing away money or its equivalent, the valuable time of a manager who must work for next to nothing, and who could, without any serious effort, find much more profitable employment. It does not pay, taking trouble and worry and accident into account.

The investor, in an undertaking of this character, will soon discover that it does not return him dividends at all commensurate with the risk of capital involved.

These small central stations form one of the two classes of electric light furnishers which make lights at an apparently low cost. The other class embraces the public institutions, municipal corporations, and the like.

In a town in New York State, of which you have all probably heard, they claim to run the lamps for 12 cents per day. The city does this at its waterworks station, and does not figure in a cent for labour, rent, interest, taxes, water, management and the like, merely charging for coal and carbons. The labour, it is claimed, costs nothing, as the fireman and engineer are there anyway, and the water departments would have to pay their wages and all other incidental expenses.

Thus these lights cost apparently an insignificant 12 cents daily. It is an absurd calculation to omit in the estimate one of the most important elements.

In Maine there is a city that runs its lights by water power, and forgets to charge up the cost or rental value of that power in making the estimates, bringing the apparent cost of lights down to 16 cents daily.

Here, in Chicago, we have the spectacle of our municipal corporation claiming to furnish lights for 19 cents daily. The absurdity of the claim, and the fallacy of the arguments in support of the claim, were commented upon at the last National Electric Light Convention.

Electric lights are run cheaper in proportion as they are run in large numbers.

Let us take up for study one of the large city plants, and see how nearly the claim of 19 cents daily is borne out by the facts as nearly as we can get at them, and there will be no serious difficulty, for the stations are run wide open, and are public in their

character. Nothing is concealed from the inquisitive searcher for knowledge.

The station in question is fitted up with mechanical stokers under 66-inch steel boilers, with the most approved setting, and is operated under a constant unvarying load. There is probably no greater variation than 10 horse-power, on a total of 500 horse-power from one day to another.

In the station referred to there are 18 dynamos belted direct from single acting automatic cut-off high speed engines, which take steam at 90 lbs. pressure, and exhaust into an improved feed water heater.

Of the 18 dynamos one or two are running idle, being in reserve. They consume very little power, not over 5 or 6 horse-power. The remainder of the dynamos are carrying a load of somewhat less than 450 lights, distributed over 30 or 40 miles of underground circuits.

Between 10 per cent. and 15 per cent. of the power is lost between the dynamo and the boiler which, added to an allowance of one horse-power for each light, gives a total of 520 horse-power being generated and consumed.

A very cheap coal is burned if we are to judge by the appearance and amount of ashes hauled out. Eight pounds per hour per horse-power, considering the style of engine used, would be a very fair measure, but to be doubly sure we will assume seven pounds per hour per horse-power; 520 multiplied by 7, gives 3,640 pounds of coal per hour.

The running time varies from eight hours in summer to fourteen hours in winter, depending upon the length of the night. The averaging is about eleven hours. It requires at least one hour's extra coaling to raise the steam before starting, as full steam must be had from the send-off, all the lights being thrown on within a period of 15 minutes. This makes a total of 12 hours, and 12 times 3,640 pounds, or 43,680 pounds of coal are used per day. At \$2.10 per ton—a very low figure—the cost of coal is \$45.86 daily. Assuming that one pound of coal evaporates seven and one-half gallons of water, there will be used daily, exclusive of water for washing out, cleaning, &c., about 44,000 gallons, which at 8 cents per 1,000 is worth \$3.49. Gas for lighting while lamps are not running comes to 15 or 20 cents daily. Let us call it 15 cents.

Carbons are used at the rate of two and one-half per lamp, or 1,125 daily, which, at \$8.50 per 1,000, cost \$9.56.

Not less than four globes will be required daily at 50 cents each, which makes \$2 per day for this item. Just here the city effects a great saving over the regular central stations and private operators of electric lights. If a globe used indoors cracks or a piece drops out, its usefulness has departed, and it must be at once replaced by a new one. Each renewal means an outlay of 45 or 50 cents. Out of doors on the lofty city poles three-fourths of the life of a globe is still in it after it has become cracked or slightly broken. It may seem strange, but the globe invariably lasts twice as long after a piece has fallen out as before, for the reason, no doubt, that it can expand and contract far more easily under great and sudden changes of temperature.

A careful inspection would show that about 80 per cent. of all globes on the street lamps in Chicago are cracked or broken; in fact, many of them are more hole than glass.

Brushes for the dynamo cost \$1 per day, carbon holders for the lamp cost fully 50 cents per day. Dynamo and lamp repairs, commutator segments and screws, insulating wood, varnish and tape, oil cup glasses, renewals and repairs of tools, emery paper, crocus cloth, pliers, carbon kits, &c., cost not a cent less than \$2 per day.

Cotton waste and wiping rags, gaskets, sheet and piston packings cost \$1 per day at a low estimate.

The amount of lubricating and cylinder oils for engines, dynamos, and pumps will be six gallons daily, which at 50 cents will cost \$3 per day.

The boilers and piping cost \$15,000. The engines and belting cost \$10,000. The dynamos and lamps cost \$18,000; total, \$43,000. Ten per cent. of this for wear and tear, and depreciation and renewals is \$4,300 annually, or \$11.77 daily.

The building cost \$20,000; 5 per cent. for depreciation and renewals is \$1,000 annually, or \$2.75 daily.

The insurance on a total of \$63,000 is not less certainly than \$1 per day. The ground is valued at \$20,000, making a total investment of \$83,000; 4½ per cent. interest on this amount is \$3,735 annually, or \$10.23 daily.

This is a total amount, so far, of \$94.32 daily, made up as follows:—

## COST OF OPERATION.

Coal	...	...	...	...	\$45 86
Water	...	...	...	...	3 49
Gas	...	...	...	...	15
Carbon points	...	...	...	...	9 56
Globes, lamp	...	...	...	...	2 00
Brushes, dynamo	...	...	...	...	1 00
Holders, carbon...	...	...	...	...	50
Incidentals	...	...	...	...	2 00
Waste and packing	...	...	...	...	1 00
Oil	...	...	...	...	3 00
Wear and tear on machinery	...	...	...	...	11 77
Wear and tear on building	...	...	...	...	2 75
Insurance	...	...	...	...	1 00
Interest	...	...	...	...	10 23
<b>Total</b>	...	...	...	...	<b>\$94 32</b>

In addition, there is the discord-breeding element of labour—costing as follows—as nearly as can be estimated without an actual reference to the pay roll.

## COST OF LABOUR.

1 chief engineer	...	...	...	\$4 00 per day.
1 first assistant	...	...	...	3 50
2 oilers at \$2.25	...	...	...	4 50
2 boiler men at \$2 25	...	...	...	4 50
4 firemen at \$2	...	...	...	8 00
2 wheelers or passers at \$1.75	...	...	...	3 50
1 watchman	...	...	...	2 00
1 line man	...	...	...	2 50
1 dynamo man	...	...	...	3 00
1 dynamo man	...	...	...	2 50
9 wiremen at \$2	...	...	...	18 00
<b>Total</b>	...	...	...	<b>\$56 00</b>

In the general official headquarters are employed, a manager, a chief electrician, a superintendent, and a clerk, at an outlay of \$30 per day for salaries. There is an additional item of \$5 per day for office expenses, stationery, incidentals, &c., a total of \$35 per day.

This, divided up among five stations, assuming that the city can operate that many plants with such an office force, gives \$7 per day as the amount to be added to the foregoing \$56 for wages daily, and the \$94.32 daily expense previously estimated, making a grand total of \$157.32 cost for each and every day, Sunday included, for the maintenance of nominally 450 lights. By simple division we find the cost to be 34½ cents daily for one light.

This is a decided difference from the claim of 19 cents made by the authorities, and spread broadcast through the country. It may be thought by some the estimate is too high. It could not be shaved more than 10 per cent., even if it were high and the cost brought down to 31 cents. The difference, on a basis of 2,000 lights, between 19 cents and 31 cents, would amount annually to \$87,600, quite a tidy little sum.

But that is immaterial, as we are not picking a quarrel with the city people, but rather making use of their experience as a guide to us in our effort to ascertain the cost of running electric lights. We do not feel inclined to allow the reduction of 10 per cent., as figured above, but hold to the opinion that the figure should rather be increased 10 per cent., that is to 38 cents or 39 cents daily per lamp, for perfect economy does not obtain in affairs political. What with incompetent and overpaid help, and there is always some of this—what with vacations, sickness, loss of time, inferior contract coal, and unexpected breakdowns—the total will invariably be considerably above our figures. Of the 34 cents, perhaps 25 per cent. is outside of what can be justly considered as operating expenses.

By operating expenses is meant everything except rent, depreciation on buildings, taxes, insurance, interest, and management.

Perhaps 26 cents or 27 cents will be a fair estimate of the actual daily running expense per lamp. This by careful business management can be somewhat reduced where the lights are used in any considerable number.

The question then arises, or may arise, how can the ordinary merchant with but a very few lights hope to produce them for less cost per lamp the city, when the latter has all the advantages inseparable from a large plant.

It must be borne in mind that there are several channels open for practicing economy, of which a public body or corporation cannot very well take advantage.

The city of Chicago follows a most liberal policy in the management of its institutions of every kind, including the electric light station. It is generous without being lavish or wasteful. It is further handicapped by long running hours, necessitating two separate shifts of men, with the accompanying heavy expense of labour. The many directions in which the private manufacturers of lights can cut down expenses have been partly brought forward in earlier portions of the paper, and partly suggest themselves. What has been done can be done again. We can repeat in our stores and shops that which we see is being done in our streets. The consumer can supply himself with arc lights for 25 cents or less, for even as little as 20 cents per day per lamp.

The lights in a large commercial house, not far distant from this location, cost approximately 21 cents per day, figuring 5 lbs. of coal per ton per horse-power with 1 horse-power, and 5 per cent. over charged to each light. The firm pays \$3.75 a ton for coal. Carbons cost \$10 per 1,000, considerably more than the price paid by the city, but the most rigid economy is practised in burning them. Not a scrap is wasted. Globes cost a little more than in the case of the city. Labour costs a little less per light. A summary of the items is about as follows:—

- Eight cents per light for fuel.
- Three cents per light for incidentals.
- Two cents per light for carbons.
- Eight cents per light for labour.

The total is 21 cents. An additional 5 cents per day per lamp will pay all the expenses, such as rent, interest, taxes, insurance, &c., and that can possibly be charged to the plant, will bring the total to 26 cents—a sum entirely within the means of the business man. The result obtained in the last case represents perhaps the utmost economy that can be attained where the lights are run as a dis-

inct department of an institution, and agrees substantially with figures taken from the books of an establishment owning and running 200 arc lights. Here is an expenditure of no less than \$52 daily. If gas was burned \$125 worth per day would not give even an approximate equivalent light.

If lights are run from a single dynamo, which is cared for by the regular engineer of the establishment, and which takes up but little or no room in his department, the expense is cut down to as low as 15 or 16 cents daily. At such figures the light is really a necessity to a shrewd live merchant. The longer such a man puts off the adoption of the light in his business, just that much longer will he be behind his electrically-lighted rivals in the race for dollars.

The light has come to stay, and has taken its place with elevators and lifts as a necessary part of the machinery of an establishment that is forced to carry on its business in tall, deep, dark buildings, hemmed in on both sides by other buildings fronting on narrow streets and shut off from the light of day. It then becomes our duty as intelligent, progressive engineers, to seek at once for a better acquaintance with this method of illumination.

It will be found a most simple mechanical problem, on a par with the other machinery intrusted to our care, and no more difficult to manage than the ordinary elevators and engines. It is not at all mysterious. The atmosphere in the immediate vicinity of dynamos, converters and electric circuits is commonly supposed to be full of flying and flurrying volts, watts, amperes and other hidden subtleties. This need, however, occasion no alarm. They keep themselves in the background, and are not nearly so troublesome as hot boxes. The thoughts of them need deter no one from undertaking a study of them.

We have no more to fear from a volt than we have from a latent heat unit. Who ever saw the engineer that was afraid of a latent unit of heat? Do not then fear the electric terms. They are but the hidden elements of the forces with which we will have to deal. Master them.

## LONDON COUNTY COUNCIL.

At the weekly meeting held on Tuesday, the following report of the Parliamentary Committee was presented:—

### *Overhead Wires Bill.*

On the 28th October last the council, on the recommendation of the Highways Committee, passed the following resolution:—"That the council's Bill relating to overhead wires, in the form in which it passed the Select Committee of the House of Commons, subject, however, to such modifications as the Parliamentary Committee may consider necessary, be again introduced into Parliament next session; and that it be referred to the Parliamentary Committee to give the requisite notices and to take the other measures necessary for the purpose." In compliance with the terms of the above instruction, we have carefully considered the Bill, and have thought it desirable to omit clause 11 of the Bill of last session, which proposed to empower the council to make orders for carrying wires over, or supporting them, or attaching them to, private property. It will be remembered that this was one of the clauses upon which the opposition in the debate, which resulted in the rejection of the Bill, was based. With this exception the Bill remains as it left the Select Committee of the House of Commons. We have directed a copy of the Bill to be sent to each member of the council, and we recommend—

That the seal of the council be affixed to the petition for leave to bring in the London Wires Bill, and that the Bill be deposited with the petition, pursuant to the Standing Orders of Parliament, with such verbal alterations (if any), as the Parliamentary Committee may consider desirable.

### *Electric Lighting.*

We have considered the following resolution passed by the council on the 18th November:—"That the Parliamentary Committee be instructed to insert in the Council's General Powers Bill of next session a clause giving the council power to require any electric lighting company to supply electrical energy to the council's electric testing stations, even if the station for which the supply is required be beyond the limits of the company's area of supply, and authorising such company, subject to the usual notices, to break up streets for the purpose of laying the mains necessary to afford such supply to the testing station." We have consulted the Parliamentary agent on the subject, and are advised by him that it is too late to insert such a clause in the General Powers Bill, the notices not having provided for it. We have accordingly referred the matter back to the Highways Committee for further consideration, and have directed the agent's report to be laid before them. We recommend—

That the reference to the Parliamentary Committee be discharged.

The Chairman of the Highways Committee presented the following report:—

The London Electric Supply Corporation has given notice (Registered No. 134) of its intention to lay a service line from the St. Martin's Vestry Hall in Charing Cross Road to the Electrical Standardising Institution in the same thoroughfare, and proposes to extend the line to the council's electric testing station in Cranbourne Street. We see no objection to the proposed works, and recommend—

(a) That the consent of the council be given to the laying by the London Electric Supply Corporation of a service line from the St. Martin's Vestry Hall, Charing Cross Road, to the Electrical Standardising Institution in the same road, and to the council's electric testing station in Cranbourne Street, upon the following conditions:—That the company do give two days' notice to the council's chief engineer before commencing the works; that the proposed line be laid in the subway; that the position to be occupied by the service line in the subway be subject to the approval of the chief engineer of the council; and that the work of placing it to be carried out to his satisfaction.

(b) That the clerk be instructed to forward to the company a notice requiring it to lay the service pipe, referred to in its notice (Registered No. 134), in the subway of the Charing Cross Road.

We have considered two notices from the Notting Hill Electric Lighting Company: one dated 14th November, 1890 (Registered No. 135), of intention to lay mains in Stanley Crescent and Gardens, and a part of Kensington Park Road (1 plan); and the other, dated 20th November, 1890 (Registered No. 136), of intention to lay mains in Pembroke Road from High Street, Notting Hill, to the corner of Ladbroke Road (1 plan). The works referred to in these notices are of the same description as those of this company previously sanctioned by the council; and we recommend—

That the sanction of the council be given to the works referred to in the notices (Registered Nos. 135 and 136), dated 14th and 20th November, 1890, respectively, of the Notting Hill Electric Lighting Company, upon condition that the company do give two days' notice to the council's chief engineer before commencing the work; that the cover stones of the culverts under 20 inches wide shall be not less than 2 inches thick, and of the wider culverts not less than 2½ inches; and that where the culverts cross the carriage-way, there shall be at least 9 inches thickness of Portland cement concrete above the cover stones of the culvert in addition to the road material.

The Kensington and Knightsbridge Electric Lighting Company has given two notices (registered Nos. 137 and 138), dated 21st and 26th November, 1890, the first being for extension of mains in Alfred Place West (1 plan), and the second for similar works in Church Street, Kensington (1 plan). There seems to us to be no objection to these works; and we recommend—

That the sanction of the council be given to the works referred to in the two notices (registered Nos. 137 and 138), of the Kensington and Knightsbridge Electric Lighting Company, dated 21st and 26th November, 1890, respectively.

The subject of the subway in its many phases has been agitating the minds of the council for some time. The Improvements Committee, in considering one section of the question, have arrived at the opinion that persons who use subways for lying pipes and wires should pay for the privilege, and at the meeting recommended an application to Parliament for powers to compel companies to use the subway, and to enable the council to charge a rent for such user.

## PRACTICAL PROBLEMS.

### *1. Provisional or Intermittent Employment of Accumulators in a Distribution of 110 Volts.*

THE first practical problem published in our paper on the 4th of October, has brought us a certain number of letters which have led us to explain more fully certain points which were, perhaps, touched upon too briefly.

The particular case which we considered, in the first place, concerned a reserve installation, in which the three or four lamps that were eventually to be fed by the accumulators would only work at long intervals—merely a few hours per week. Under these conditions, a current charging 3 to 4 ampères 3 or 4 hours a day, supplied every day to the battery from 10 to 15 ampère-hours, or from 60 to 90 ampère-hours per week, a quantity sufficient to feed the lamps kept in reserve for night service or any similar purpose.

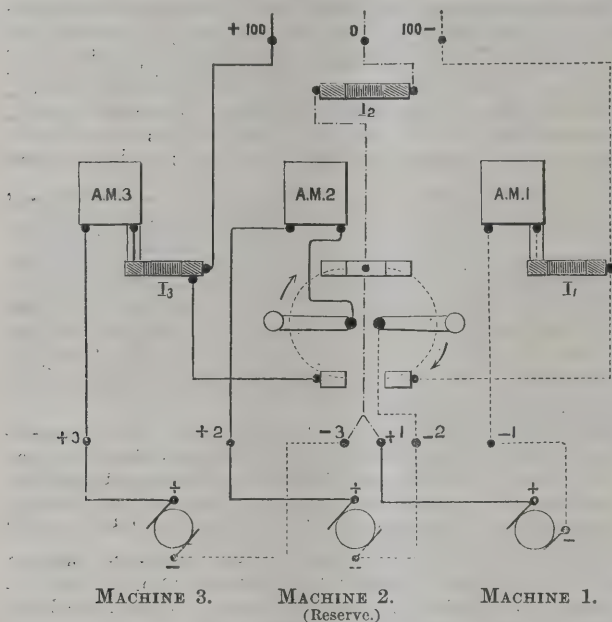

When the lamps are to work every day, it is evident that the number of 75-volt lamps placed in circuit with the battery of accumulators during the charge must be increased. The number of these lamps must be calculated in such a manner that the mean daily charge of the battery in ampère-hours exceeds by 10 to 15 per cent. the mean daily consumption in ampère-hours of the lamps supplied directly by the accumulators during the stoppage of the machine, this excess of 10 to 15 per cent. being calculated to take into account the rendering in quantity of the accumulators.

We do not think it necessary to give a diagram of

the mounting of the apparatus, it being very simple, and yet varying considerably according to the requirements of each case.

## 2. The Mounting of a System of Distribution with Three Wires.

The distributions with three wires, which are now pretty generally used, are particularly suited to the requirements of a small town, the population of which is not large enough for a service of distribution to be conveniently arranged with two wires, but yet too large for alternating currents and transformers to be employed.

The case of most frequent occurrence is that in which three shunt dynamos are used, two of which work at the same time, the third remaining in reserve, so as to be ready to be quickly substituted for one of the two others. Several methods have been adopted of connecting the system of canalisation with the machines and effecting readily the change of machines. One of the most simple is that adopted at the Cerlikon works, and which we have shown above. The six lower terminals of the system are connected respectively with the three shunt dynamos, 1, 2 and 3, machine 2 being the one in reserve, and the three upper terminals with the three distributing wires. Three ampèremeters are introduced respectively into the circuits of the three machines, in order to enable one machine to be substituted for another without any interruption of the service, by a simple manipulation of the exciting rheostats of the two machines between which the charge is to be effected. Three interrupters,  $I_1$ ,  $I_2$ ,  $I_3$ , enable the three lines of the system to be completely insulated, in order to facilitate the testing of the insulation of the circuit of distribution.

Without dwelling further on the many advantages of this method over the distribution by two wires in the case under consideration, we will merely mention one that has up to the present been almost overlooked, and which consists in carrying on the distribution after midnight by means of a single machine, whilst two working at 200 volts can be employed for the full service, from nightfall to midnight. The plan of distribution must, in this case, be modified, the connection of the two circuits with one machine entailing a special manipulation which, however, presents no difficulty.—*L'Electricien*, October 18th, 1890.

## LONDON GAZETTE NOTICES.

### Provisional Orders.

ACCORDING to the *London Gazette* for the 28th November, the following corporations and public companies will apply to the Board of Trade for provisional orders ;

Surbiton Improvement Commissioners ; Whitby Local Board ; Harrogate Corporation ; Tunbridge Wells Corporation ; Torquay Local Board ; South Shields Corporation ; Electric Installation and Maintenance Company (Maidstone and Leeds) ; Camberwell and Islington Electric Light and Power Supply ; Paddington and Bayswater Electric Light and Power Supply ; Yorkshire House-to-House Electricity Co. (Leeds) ; Stamford Hill, Tottenham and Edmonton Electric Light and Power Supply (Hampstead and Wandsworth) ; Laing, Wharton and Down Construction Syndicate (Whitechapel, Hackney and Shoreditch) ; Brush Electrical Engineering Company (City of London, Southwark, North of London, and Poole) ; Messrs. Latimer-Clark, Muirhead & Co. (St. Martin's-in-the-Fields) ; Provincial Electric Light and Power Supply (Aberystwyth) ; Ipswich Electricity Supply Company, Messrs. Laurence, Scott & Co. (Ipswich) ; Windsor and Eton Electric Light Company ; Manchester House-to-House Electricity Company (Withington District) ; Weymouth Electricity Supply Company.

### Tramways.

The Birmingham Corporation and the Bristol Tramways and Carriage Company, in seeking authority to construct new tramways, specify electricity among other methods of traction which they ask permission to use.

## PARLIAMENTARY NOTES.

### The Wreck of the *Serpent*.

IN the House of Commons on Wednesday last, Lord George Hamilton, in reply to a question as to ships' compasses said :—There were four compasses on board the *Serpent*, including two of Sir William Thomson's, and they were adjusted and inspected on July 6th and November 8th this year. The compasses were inspected after the manœuvres by the superintendent of compasses, and found in excellent order. On the occasion of a subsequent visit, the commander expressed his own and the navigating officer's great satisfaction with the behaviour of compasses during heavy weather in the manœuvres of 1890. Sir W. Thomson's compasses were introduced into the navy in 1884, and there are now very few of Her Majesty's sea-going ships that have not at least one.

### Telegrams.

Last Friday, Mr. Hobhouse asked the Postmaster-General if it was the rule of the telegraphic department of the General Post Office to refuse to compensate persons for loss or expense consequent on the loss, delay, or non-delivery of a telegram, and to refuse to communicate to the person injured the names of the defaulting office or officials. Mr. Raikes in reply said :—If the hon. member will be so good as to refer to clause 6 of the notice which is printed on the back of the forms on which the public write their telegrams, he will find an answer to the first part of his question. The clause reads as follows :—“The Postmaster General will not be liable for any loss or damage which may be incurred or sustained by reason or on account of any mistake or default in the transmission or delivery of a telegram.” As to the latter part of the hon. member's question, I may say that it is not the practice to give the names of the subordinate officials concerned in the transmission of a telegram or to name the office where a mistake may have occurred. Indeed, in a great many cases it would be impossible to do so, as it cannot always be ascertained with certainty where the fault has occurred or whether it is not due to some momentary disturbance of the wires or other apparatus. The conduct of any defaulting officials is always made the subject of strict inquiry by the department.

## PROFESSOR HERTZ.

A LUNCHEON was given on November 30th at the Langham Hotel by Prof. W. E. Ayrton. This gathering of a few celebrities, more especially of those belonging to the electrical branch of the scientific world, had been invited to meet Prof. Heinrich Hertz. It is well known that this gentleman has been just presented with the Rumford Medal by the Fellows of the Royal Society, as a recognition of his valuable work in carrying on Clerk-Maxwell's investigations, and showing the connection between light and electricity. The luncheon was followed by a crowded reception, at which Prof. and Mrs. Ayrton welcomed, among others, Sir Frederick and Lady Abel, Dr. Lodge, Prof. Poynting, Dr. and Mrs. Hopkinson, Mr. and Mrs. Crookes, Mr. Norman Lockyer, Mrs. Fawcett, Prof. and Mrs. Hughes, Prof. and Mrs. Perry, Prof. Foster, Prof. and Miss Thorpe.

We need hardly say that everyone was eager to see the lion of the day. Heinrich Hertz is quite a young man, for he is only thirty-three; he is slightly built; of a pleasing, but by no means German, cast of countenance; he speaks English fluently, as was plainly shown at the dinner given by the Royal Society. He used to act as assistant to Prof. Helmholtz; but on his marriage he removed to Bonn, where he holds office as a Professor of Physics in the University. It was pleasant to hear how his attention had first been attracted by a simple laboratory observation, which led him ultimately to the successful termination of his labours. He may have contributed only one pillar towards the support of that arch upon which science has to build a superstructure, but, we take leave to say, that the pillar is a very substantial pillar. It is no slight work to have shown how electricity can, like light, be reflected and refracted; like light also it goes in straight lines, and its flash can be stopped by the interposition of a suitable apparatus; that its waves are transversal and not longitudinal. By his experiments and his conclusions Prof. Hertz has much simplified all work on radiation.

## THE DINNER OF THE ROYAL SOCIETY.

(By A FESTIVE FELLOW.)

"WERE you at the dinner of the Royal Society?"

"No, sir, I was not. But as, I suppose, it was a grand day for electricians, I should much like to hear all about it from one who is acknowledged to be a light, indeed, in the electrical world."

"You are very kind. I must confess I felt very proud when I saw Sir William Thomson in the chair at our annual dinner in the Hôtel Métropole. It seemed too, that a Scotchman should occupy the chief place in a Society whose anniversary day is that dedicated to St. Andrew."

"Excuse me, but St. Andrew's Day is on November 30th, and you dined on—"

"The 1st of December. Quite so; but, you see, the 30th was on a Sunday; remember the weaker brethren. It would have been shocking to have a Presidential address and a dinner on the Sunday. Science, like other business, stands still on that day."

"Dear me, and does electricity cease to give light on that day, and sewers to give forth noxious gases, and fogs—"

"Pardon the interruption, but let me tell you about the dinner; that's a much pleasanter subject. I need not tell you that Stokes and Lubbock were there; the Lord Chancellor and a Marquis, the Italian Ambassador and Sir Philip Magnus. Professors abounded; Huxley and Hughes, Adams and Seeley, Hertz and Ayrton, Darwin and Lodge; sirs not a few—Sir D. Galton, Sir F. Abel, Sir B. Samuelson, Sir John—I mean—Sir Risdon Bennett, Sir A. This and Sir B. That; Doctors

of medicine and of science; and the power of the purse was finely represented by the Masters of the Drapers' and Clothworkers' Companies. There were the heroes of the evening, the medallists, Prof. Simon Newcomb—no, he was absent—Prof. Hertz, Prof. Ferrier, Dr. J. Hopkinson, Mr. Lockyer and Mr. Crookes."

"Very interesting, no doubt; but after all, you know, a list of names, even of scientifically intellectual giants, is rather—"

"What a Philistine you are. Would you like me to give you the *menu*?"

"No, I wouldn't—certainly not; it's quite enough for me to know that you had your dinner at the Hôtel Métropole, and as you had invited the Masters of two great City Companies, I expect you put your best feet foremost and had a sumptuous 'bankwet,' as Robert would say. Tell me some of the coruscations of wit and fancy, which must have flashed electrically through the dining room."

"Well, sir, I don't know what you mean to insinuate, but when I am asked by a gentleman to give an account of a dinner, I expect to be allowed to tell it my own way."

"Of course; quite right; so you shall. You were saying, I think, sir, that the new President—"

"Yes, sir. I was going to say (only you interrupted me) that the new President proposed, on the removal of the cloth, the health of 'The Queen and Royal Family,' and rightly dwelt upon the loyalty of the Royal Society, for we are loyal and royal. Then came 'Her Majesty's Ministers and the Members of the Legislature.' This gave Sir William an opening to compare the Constitution to an engine, which had the imperfection of not working backwards, and not being free from friction. If a perfect engine was nearly realised in a steam engine, some slight approach to perfection might reasonably be looked for in the political machine. Anyhow, H.M. Ministers showed great devotion to the public service."

"How did Lord Halsbury take the suggestion?"

"Very good humouredly. He explained that the political engine was put together with very animated bolts and screws, so that much friction was unavoidable. He went on to propose the toast of 'The Royal Society,' introducing it with an anecdote about an orator, who asked a friend what he should say on a particular occasion. 'To whom are you going to talk?' 'Oh, I'm going to talk to the Athenians.' 'Well, if you say something pleasant about the Athenians, they are sure to cheer you.' Acting upon this thought, the Lord Chancellor reminded his fellow-guests, how the light which enabled them to see each other was due to the researches of Sir William and men like him, who had made the great physical energies of the universe subservient to the use of mankind. He modestly drew in his horns after that; he felt nervous—"

"That's good! Lord Halsbury nervous! Beg pardon; you were saying—"

"He felt nervous lest some F.R.S. should tell him electricity was not physical, and was not an energy. Then he made the somewhat trite remark that electricity enabled us to receive news almost simultaneously from all parts of the world. To the legal mind, accustomed to the slow rate at which justice travels, I have no doubt this is an impressive fact about electricity."

"Did the president make a good speech in reply?"

"He very courteously, as the Italian ambassador was present, mentioned that the Academia in Florence and other societies were older than the Royal Society. But still two centuries and a half was a good age humanly, though not geologically speaking, and the Royal Society has been the fruitful parent of philosophical societies everywhere. By way of novelty, Sir William carried us back to what the Society did in the first 20 years of its existence. It took Newton—Sir Isaac Newton, you know—by the hand, and made known to the world outside Cambridge all his labours in optical research. Newton might be almost called the spoilt darling of the Society, for it was due to the indefatigable labours of

the Society's secretaries that Newton's work between 1665 and 1682 were published to the world. To Hook and Halley were chiefly due the publication of the 'Principia Mathematica de Motu Corporum.' Sir William ended modestly enough; for while he felt the high honour conferred upon him, he could not but think that all credit for the Society's good work must be given to the Society's permanent officers. But the President's work was not over. He was up again, without even the interval of a song, to propose the medallists. Here again he enlarged rather more than was agreeable to most of his audience, upon the special work of some of the medallists; as he had given us a most detailed account of Newton, so he elaborated upon Newcomb and the rest. However, all things come to an end. It was time for Dr. Hopkinson to reply to the toast. With an occasional reference to notes, he told us how Newcomb had advanced Newton's theory of gravitation by applying it to the details of the motion of the moon and other planetary bodies; how Prof. Emil Fischer had furthered chemistry by synthetically producing from inorganic sources many definite sugars; how Wallace had chivalrously given way to Darwin; how Dr. Ferrier worked on the surgical treatment of the brain. When he reached that point, he bitterly denounced the restrictions on experimental work. I have no doubt he will hear further about that part of his speech from Miss Cobbe and the *Spectator*. With a pretty compliment to his foster-father in electrical and magnetic science, Sir William Thomson, that speech was ended. Our Bonn Professor, Hertz, next claimed our attention with a capitally-delivered speech, entirely in English, and spoken without any notes. He was fully aware of the high honour which had been done him. His only ground of apprehension when treading on English soil was that he would have to encounter a certain feeling of national jealousy; but, on the contrary, his first and most friendly communication was with those who might in ignorance be called his rivals, Dr. Lodge and Prof. FitzGerald. He was glad he had come to England to receive this medal, which was an earnest indeed of future work; for so had he seen, face to face, men whom hitherto he had worshipped only at a distance. Of this he was sure, that his work, so kindly praised, would sooner or later have been done by the men who so heartily welcomed him."

"Was there much more speech-making?"

"Sir John Lubbock proposed 'The Retiring President.' Perhaps, as you hail from Cambridge, you know the work he has done on the steady motion of incompressible fluids, on crystals and spectrum analysis. In reply, Sir Gabriel stated that he owed much to the Cambridge Philosophical Society, and, though he was retiring from the presidentship, he had no intention of resting from his labours as a member of the Council of the Royal Society. After 'Our Guests' had been proposed, and the Italian Ambassador and Sir Edward Hamley had replied to the same, we all said 'Good night,' and went our several ways."

## REVIEWS.

*Electric Bell Construction.* By F. C. ALLSOP. E. and F. N. Spon, 125, Strand, London.

The substance of this book appeared as a series of articles in the *English Mechanic*. The work is thoroughly practical in its character, and is also very complete, almost every variety of bells and their allied mechanism being fully and carefully described. We are somewhat surprised, however, to find not a word said upon the construction of the Leclanché battery, indeed, the opening chapter, in which the general principle of a battery is described, might almost lead anyone to imagine that the Leclanché battery consists of a plate of copper and one of zinc in dilute sulphuric acid. Again, the description of the joining up of several cells

in series would certainly lead one to suppose that Leclanché cells had no resistance, which is very far from being the case. A feature in the book is the fact that all the illustrations are drawn to scale, so that the dimensions of any of the apparatus can at once be obtained. Magneto as well as battery bells are described, and all details of their construction very fully explained. Altogether the book is a decidedly useful one.

*Practical Electrical Notes and Definitions.* By W. Perren Maycock. Second Edition. E. and F. N. Spon, 125, Strand, London.

The second edition of this book is a decided advance on the first, though we observe that the rhapsodical rubbish, to which we drew attention in our notice of the first edition, still remains. The book, in its present form, hardly accords with its shape, which is of the pocket-book pattern, and we do not expect in such books to find illustrations of machines which are left undescribed, though, possibly, these illustrations may be useful to amateurs as a means of identifying any particular machine they may come across. On page 203, it is stated that a microphonic relay receives a message and transmits it afresh over another section of line; we are quite certain Mr. Maycock has never seen such a relay at work, for no one has yet succeeded in making one. Although the whole work contains much useful matter in the shape of notes, tables, diagrams, rules, &c., there is, we think, a good deal too much space devoted to "definitions," which are unsatisfying in their character, and might be more profitably replaced by something more practical. We notice that the use of the modern terms "conductance," "resistivity," &c., has been introduced. The whole work has had the advantage of having been "overlooked" by Professor Silvanus Thompson and Mr. J. Swinburne; quite so!

*The Electric Light Popularly Explained.* By A. BROMLEY HOLMES. 5th edition. London: Bemrose and Sons, 23, Old Bailey.

The first edition of this book was published in 1882, and the fact that a fifth edition has been called for speaks well for the production. A good deal of additional matter has been worked in and revision carried out. The last chapter, which deals with the "Cost of the Light," is, perhaps, hardly entirely satisfactory; but, then, the subject is one which it seems almost impossible to fairly get at.

*Physical Memoirs: selected and translated from foreign sources, under the direction of the Physical Society of London.* Vol. I., part 3. London: Taylor and Francis, Red Lion Court, Fleet Street.

This issue consists of a paper by Prof. J. D. Van der Waals, on "The Continuity of the Liquid and Gaseous States of Matter."

## THE QUESTION OF PUBLIC LIGHTING IN BUDAPEST.

[FROM A CORRESPONDENT.]

BY the occasional insertion of moderately circumstantial communications, you have kept your readers acquainted with the different phases of this question in Budapest. They will probably read with interest the following extract from the recent report of the Commission on Public Lighting, especially as it furnishes a clear view of the genetic development of this affair, which is calculated to prove instructive to other municipal bodies.

The sub-committee appointed for the especial conduct of the negotiations obtained in the first place an opinion from the Director of Buildings (an official somewhat like the "Dean of Guild" in a Scottish

city), the head accountant, and the chief fiscal. The prevalent opinion, in accordance with the explanations received, was to the effect that "in view of the revolution now taking place in the sphere of public lighting, it did not appear suitable to take the use of any other new means of lighting into serious consideration, and that "the question of the redemption of the gas-works could be advantageously considered only if the valuation provided for in the agreement had been carried out, and the capital required for the redemption had been approximately estimated. All this, however, was no reason why the metropolis should not make use of the right secured to it under section 4 of the gas agreement, concerning the (partial) adoption of a new system of lighting.

Proceeding from the point of view just indicated, the sub-committee invited the gas company to declare whether, and under what conditions, it was prepared to supply electric lights, on the one hand, for public purposes, and, on the other, for private consumers. Further negotiations were to be opened with the gas company to ascertain whether, and under what conditions, it was prepared to concede a reduction of price for the private consumption of gas before the expiry of the agreement, and undertake the private lighting gratuitously?

The gas company replied, in the communication of September 5th, 1889, that, in accordance with the wish of the city, it was prepared to undertake the introduction of the electric light on certain conditions (enumerated in detail), and in return for a prolongation of the gas agreement for 10 years, gradually to reduce the price of gas to private consumers to 11 kreutzers, and to supply the street lighting gratuitously on the basis of the quantity consumed in 1888, so that the city would only have to keep the street lamps in order.

After ripe deliberations, the sub-committee resolved that the conditions for the introduction of the electric light were too onerous, and that the gas company would thus obtain a monopoly of the electric light. Hence the offer, as it stood, could not be accepted, but, with considerable modifications, it might be taken as the basis of further negotiations. "Hence the sub-committee—considering that the redemption of the gas-works would be unreasonable, since there is a general movement in the matter of public lighting, and new technical advances and inventions are daily coming forward—did not object to a prolongation of the agreement, but urge that it must be made a fundamental principle that with such prolongation the monopoly of the gas company for the introduction of any illuminating agent must expire, and the capital must have its hands in this respect unfettered. The conditions of the committee were in fine the following: A ten years' prolongation of the gas agreement, reduction of the price of gas to private consumers to 10 kreutzers per cubic meter; free supply of the street lamps without reimbursement for the expense of their erection; no exclusive right or privilege for the electric or any other new light; finally, the stipulation that the price of the electric light for the street lamps must not be higher than that of the gas lamps at present.

On March 31st, 1890, the desired explanation of the gas company was handed in. It was willing to forego the exclusive right of introducing any new means of illumination which had been secured to it by contract. If the gas agreement were prolonged for 15 years the company was willing to concede to the municipality the unlimited right of disposal; the price of the gas supplied to the private consumers should be reduced to 10½ kreutzers; the gas required for street lighting should be furnished gratuitously after the expiry of the present agreement, and after the cost incurred for maintaining the lamps according to the proportion of 1888 had been refunded.

The municipal accountant calculated that these conditions—disregarding the great value which the surrender of the exclusive privilege possesses—would involve yearly a saving to private companies of 1,250,000 florins during the time of the present agreement, and that it would imply for the community a yearly

economy of 240,000 florins, dating from December 16th, 1895, and it would consequently be acceptable with the following modifications and additions. 1, The city is to be free after 10 years to redeem the gasworks; 2, the private gas price to be reduced to 10 kreutzers; 3, half the cost of the street lighting is to be at once given up, and the rest after the expiry of the present agreement; 4, the city to refund only half the cost of maintenance of the gas-lamps; 5, the gas to be supplied gratis for the streets is to be calculated according to the consumption of 1889, taken as a minimum; 6, the gas company to establish an independent management in Budapest.

To these more recent proposals the gas company replied on June 12th, 1890. The redemption of the gasworks before the expiry of the 15 years cannot be accepted; the company accepts the reduction of the private gas price to 10 kreutzers, on condition that the production cost of gas does not rise, and that no further sacrifices are to be required for public purposes. The immediate surrender of half the cost of public lighting, and half the cost of maintaining the lamps cannot be conceded. The proportion of consumption for 1889 is accepted, but not as a minimum, but either as a fixed or a variable yield. The local direction of the gas company will be invested with powers to decide on the spot all affairs concerning the Budapest Gas Works.

Therewith the negotiations were completed, and the General Commission resolved to accept the offers of the gas company, with the following supplements:—The ultimate redemption of the gas works will not take place before the lapse of 15 years' agreement; the price for private gas, not to be used for lighting, to be reduced to 8 kreutzers per cubic metre; the proportion of consumption of the gas to be supplied gratis for street lighting is to be assumed as variable, adhering to the proportions of 1889. Several gas testing stations are to be erected in the city, and the price of the gas consumed in municipal buildings is to remain in future 7.42 kreutzers for cubic metre.

## NOTES.

**Removal.**—Messrs. Nalder Bros. have now removed their offices and works to their new premises at 16, Red Lion Street, Clerkenwell.

**Fire at an Electrical Engineers.**—Last Saturday afternoon a fire broke out on the premises of Messrs. Gent and Co., electricians, Leicester. It was, however, extinguished before much damage was done.

**The Delany Battery Strip.**—This is a simple contrivance, invented by P. B. Delany, of South Orange, N.J., to prevent the creeping of salts in the gravity, Leclanché, and other primary batteries. The device is simply a strip made of rubber cloth and applied to the inside of the rim of the battery jar. One side of the strip is covered with a sticky compound, and when the strip is properly applied it will never come off the jar. The strip offers a mechanical obstruction to the creeping salt which masses underneath it, and is re-dissolved in the battery fluid each time that water is added to the solution to make up for evaporation. All waste and exhaustion of batteries by local action by this means, it is claimed, is prevented, and shelves are kept perfectly clean and dry. When the strip is properly applied no amount of washing or wetting will affect it.

**Telephonic Communication with Lighthouses.**—Henley's Telegraph Works have recently manufactured a submarine telephone cable which has been laid by the Pilot authorities in Finland between Hanzo, the most southern point of Finland, to a lighthouse 2½ miles from the coast. We hear that the cable has been found to work well.

**Royal Society's Medal.**—Dr. Hopkinson will receive the Royal Society's medal for his researches in magnetism and electricity.

**Proposed Electric Railway in Vienna.**—In connection with the underground railway projected for Vienna, the Austrian Minister of Commerce has resolved to send two engineers to London to study the underground electric railway recently established between the City and South London.

**The Old Students' Association.**—The first smoking concert of the season, in connection with this association, was held at Mason's Hall Tavern on the 28th ult., Mr. W. B. Esson, the president, occupying the chair. The musical programme was of a first-class character, and in point of numbers the concert was a great success, there being not an empty seat in the room. Amongst those present were:—Vice-Presidents A. Reckenzaun and A. T. Snell, Past-Presidents Dr. W. E. Sumpner and Mr. Adams, Profs. Ayrton and Perry, Mr. L. B. Atkinson, Mr. John Gray, B.Sc.; and Mr. Holland, B.A. A cordial vote of thanks was given to the performers and to the musical committee. There is but little doubt that the O.S.A. has reached a new era in its existence, and with such energetic directors there is now nothing to prevent its growth into a body which will eventually fill an important position in the scientific world, and at the same time possess social qualifications which will keep its members continually in touch with one another.

An ordinary general meeting was held at Finsbury Technical College last night, when a paper was read by Hamilton Kilgour, member, on "Notes on Economy of Conductors in Systems of Distribution in Electrical Energy."

**S.S. Silvertown.**—This telegraph steamer, owned by the India-Rubber, Gutta-Percha, and Telegraph Works Company, is reported to have arrived at Coronel (Chile) on November 25. It will be remembered that she carries the submarine cable for extending the Central and South American Telegraph Company's lines from Lima, where they at present terminate, to Yquique and Valparaiso.

**A French Manufactory of Submarine Cables.**—A Calais telegram to the *Temps* says:—The factory for the manufacture of submarine cables, which the General Telephone Company is constructing at Calais, to the east of the Carnot basin, is finished. The opening will take place, we are told, in the early part of December. The building of this factory is, from a national point of view, of real importance, since, up till now, England alone possessed a monopoly of submarine cable-making.

**The Aron Meter.**—Dr. Aron's electricity meter received a gold medal at this year's exhibition at Palais de la Industries at Paris.

**Provisional Orders.**—The time limited by the Electric Lighting Act within which official notice must be given of all provisional orders, expired on the 28th ult. From the notices given it appears that 76 separate orders will be applied for, 17 of them relating to various portions of London and suburbs.

**Electric Light in Hampstead.**—The Hampstead Vestry will oppose all applications made by companies or others to the Board of Trade for powers to light the borough by electricity. It has empowered its Electric Lighting Committee to obtain a plan and estimate from a specialist so that it may consider the advisability of undertaking the work itself.

**Theatre Lighting.**—Messrs. Dickinson & Co. have secured from Mr. Norman Forbes a contract to install the electric light throughout the Globe Theatre.

**Mr. Muirhead and the National Telephone Company.**—We have received another and rather lengthy letter from Mr. Muirhead, which, however, shows no improvement in the relations with the telephone company. We do not see that anything is to be gained on either side by allowing further correspondence on this subject.

**Gas and Electricity in Bordeaux.**—The Bordeaux Gas Company is now lighting the stage of the Grand Theatre by electricity. The offices of the company are also lighted electrically, and the plant is installed on the latter's premises.

**New Telegraph Cable.**—A Bill approving of the agreement made on October 12th last with the Grande Compagnie des Telegraphes du Nord for the laying and working of a second cable between Calais and Fanoë in Denmark has been presented to the French Chamber of Deputies. The new convention reserves to the State certain advantages, in exchange for which it gives to the company financial assistance, which, for the two cables, will not exceed £6,800.

**New Central Station in Vienna.**—The central station of the International Electricity Company was put in operation on the 14th ult. About 21 miles of cable have been laid throughout the town and suburbs.

**Lighting of Karáusebes.**—This small town in the south of Hungary is now lighted electrically, the plant being installed in a saw mill. In addition to the public illumination, 500 lamps for private consumers are in use.

**New Battery Company.**—The Compagnie Francaise des Piles Universelles has been formed in Paris with a capital of £8,000 divided into 200 shares of £40 each.

**Edinburgh Exhibition.**—In our notice of the exhibits at the Edinburgh Electrical Exhibition, we called attention to the very fine display made by Messrs. Buller, Jobson & Co., Limited, now Bullers, Limited, of Birmingham, Hanley, Dudley, Glasgow and London, of telegraph insulators, brackets, clips, poles, stay rods, channel arms, and all the various articles made by them for telegraphic, telephonic and electric lighting purposes. Facing the index to advertisements will be found an illustration of this unique exhibit, which arrested the attention of every visitor to the machinery hall. This old-established firm, as our readers are aware, has lately purchased an extensive site at Cheston Road, Birmingham, for the erection of a new works with modern plant, suitable for the production of its manufactures. Those engaged in telephage will be interested to know that Messrs. Bullers, Limited, are supplying an insulator patented by Mr. E. J. Chambers (a director of the company), which is arranged to grip and insulate the cable at the same time, and to allow the grooved wheels of the travelling carriage to pass easily over the tops. These insulators are shown at the left hand corner of the illustration. We understand that Messrs. Bullers, Limited, will exhibit at the Glasgow Industrial Exhibition.

**Electric Welding.**—Sir Douglas Galton, K.C.B., Mr. W. H. Preece, F.R.S., Mr. Ashton (of the Royal Laboratory, Woolwich), and other gentlemen, visited Messrs. Lloyd and Lloyd's Coombes Wood Tube Works on Friday last, for the purpose of inspecting their installation of electric welding. The process used is that known as the Bernardos process, the sole right to the use of which has been acquired by Messrs. Lloyd and Lloyd, and the welding is, as our readers are already aware, effected by means of the arc. The distinguished visitors were much delighted with all they saw, and expressed themselves most favourably as to the achievements and possibilities of arc welding.

**Telephony on the Congo.**—The *Ville de Ramanah*, which recently left Antwerp for the Congo, had on board the wires, &c., necessary for the installation of the first telephone line to be erected along the Congo railway. The wire is of phosphor bronze, and the apparatus is of the type adopted by the administration of the Belgian Telegraphs for their private and service lines.

**The Institution of Electrical Engineers.**—The annual general meeting of the Institution will be held on Thursday, December 11th, at 8 o'clock in the evening, for the reception of the annual report of the Council, and for the election of Council and officers for the year 1891. The following papers will be further discussed:—"The Efficiency of Secondary Cells." "On the Chemistry of Secondary Cells." By Prof. W. E. Ayrton, F.R.S., Vice-President, C. G. Lamb, B.Sc., and E. W. Smith, Associates.

**Telephone Switchboards.**—We have received a long communication from Mr. Hubert F. Jackson on "Improvements in Telephone Exchange Switchboards." Unfortunately it came to hand after the bulk of our pages had gone to press, so we must perforce hold it over till next week.

**Death from Electricity.**—Reuter telegraphs from St. Louis, United States:—An electric light company's employé came into contact with an electric light wire here on Saturday and was immediately killed.

## NEW COMPANIES REGISTERED.

**Holmes and Sons, Limited.**—Capital £14,000, in £5 shares. Objects: To take over the business of Holmes and Sons, engineers, of Norwich, and to trade as mechanical engineers, machinists, metallurgists, and electricians. Signatories (with 1 share each): \*Garrett Taylor, \*James Holmes, \*G. T. Holmes, F. R. Holmes, all of Norwich; \*Clare Sewell Read, Thorpe, Norfolk; \*C. Waters, Postwick, Norfolk; \*J. W. Reynolds, Keswick, Norfolk. The signatories denoted by an asterisk are the first directors. Qualification, 50 shares. Remuneration, £150 per annum, divisible. Registered 24th inst. Solicitor, Mr. S. Cozens Hardy, Norwich.

**Weymersch Electric Battery Company, Limited.**—Capital, £20,000 in £5 shares. Objects:—To carry on the business of an electric light company in all branches, and to enter into an agreement with Hy. Weymersch, Leoné Sara McKenzie and Arthur McKenzie Cardwell. Signatories (with 1 share each): \*A. M. Cardwell, 29, St. James' Street; \*H. Weymersch, 17, Glengarry Road, E. Dulwich; W. S. T. Martin, 17, Melbourne Grove, E. Dulwich; E. C. de Segundo, 7, Victoria Street, Westminster; F. Fanta, 10, Moorgate Street; C. F. Jones, Fox Hill, Upper Norwood; Mrs. L. S. McKenzie, 21, Talbot Road, Bayswater. The first directors are the first two signatories and T. H. Cardwell and W. A. Cardwell. Qualification, 100 ordinary shares, and the company in general meeting will determine the remuneration. Registered, 28th ult., by Harwood and Stephenson, 31, Lombard Street. Registered office, 2, Victoria Mansions.

**J. & S. Roberts, Limited.**—Capital, £120,000 in £10 shares. Objects:—To take over the business of ironfounders carried on by Messrs. John and Samuel Roberts at the Swan and Small Heath Foundries, West Bromwich, and to carry on business as ironmasters, mechanical and electrical engineers and manufacturers of electric plant and appliances. Signatories (with 1 share each): \*John Roberts, \*S. Roberts, \*J. Hampton; James Roberts, \*Hy. Roberts, Thos. Roberts and W. A. Roberts, all of West Bromwich. The signatories denoted by an asterisk and H. J. Roberts, Isaac Jenks and Walter Jenks are the first directors. Qualification, 50 fully paid ordinary shares. Registered, 20th ult., by Sharpe, Parker & Co., 12, New Court, Carey Street.

## OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Elmore's French Patent Copper-Depositing Company, Limited.**—An agreement of 10th September between Elmore's Foreign and Colonial Copper-Depositing Company, Limited (the vendors), of the first part, Woodhouse and Rawson United, Limited, of the second part, and this company of the third part, provides for the sale to this company of the French patents of the vendor company, the consideration being as follows: £8,350 within seven days of going to allotment, £75,150 in cash, and £66,500 in fully paid shares, and a premium of 10s. each on any of the 66,750 shares issued to the public which may be allotted to any person or persons other than the vendors. Provided always that should the Woodhouse Company consider that applications for shares in this company, over and above those to be allotted to the vendors are insufficient, then the company shall be at liberty to pay any part of the said cash in fully paid shares at par. Under this agreement Francis Edward Elmore and Alexr. Stanley Elmore are appointed standing consulting metallurgical chemists of the company for three years at a remuneration of £100 per annum each. Registered office, 64, Cannon Street.

**Elmore's Austro-Hungarian Patent Copper Depositing Company, Limited.**—An agreement of 26th September, filed 20th October, provides for the purchase by this company of the patents for Austria-Hungary belonging to Elmore's Foreign and Colonial Patent Copper-Depositing Company, Limited. The purchase consideration is £10,000 in cash within seven days of going to allotment; secondly, £40,000 in cash and £50,000 in fully paid shares, and a premium of 10s. each on any of the 75,000 shares issued to the public which may be allotted to any person or persons other than the vendors, with the same discretionary power to the Woodhouse Company as in the French Company, for the payment of any part of the said cash in fully paid shares at par. Messrs. Francis Edward Elmore and Alexr. Stanley Elmore are appointed standing consulting metallurgical chemists of the company, at a remuneration of £100 per annum each.

**Metropolitan Electric Supply Company, Limited.**—The annual return of this company, made up to the 21st ult., was filed 27th ult. The nominal capital is £500,000, divided into 49,900 ordinary, and 100 founders' shares of £10 each. The shares taken up are 45,932 ordinary, and 100 founders', and of these 2,132 are considered as fully paid. Upon 43,900 shares £8 per share has been called, the calls paid amounting to £342,598 9s., and unpaid to £8,601 11s.

**Brazilian Submarine Telegraph Company, Limited.**—The directors of this company have to-day declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum.

## TRAFFIC RECEIPTS

The Cuba Submarine Telegraph Company, Limited. The estimated traffic receipts for the month of November were £3,100 as compared with £3,112 in the corresponding month of last year. The receipts for the month of August estimated at £2,900, realised £2,913.

The Direct Spanish Telegraph Company, Limited. The estimated receipts for the month of November show £2,732 against £2,497 in the corresponding period of last year.

The Eastern Extension, Australasia and China Telegraph Company, Limited. The receipts for the month of November, 1890, amounted to £44,742, as against £44,147 in the corresponding period, an increase of £595.

The Eastern Telegraph Company, Limited. The receipts for the month of November were £58,975, as against £60,578 for the same period of 1889, or a decrease of £1,603.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending November 28th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £5,116.

The West Coast of America Telegraph Company, Limited. The gross earnings for the month of November, 1890, were £4,850.

From this it appears that the resistance per inch of the lug alone is about 0.000043 ohm; and that the resistance at the contact of two lugs which were tightly screwed together when quite clean, but which have become very dirty from the acid spray falling on them, may be as high as 0.001 ohm, or thirty times the resistance of an inch of the lug itself. The resistance between r and o, fig. 9, being greater than between k and l, when r was very dirty, is probably explained by the fact that when the wire was screwed under r to test the resistance between r and o, fig. 9, it was screwed against an exceptionally dirty bit of the lug.

As we have shown in the Edinburgh paper, the mean resistance from positive lug to negative lug of one of these accumulators complete is about 0.004 ohm when the contacts between the lugs and the testing wires are made quite clean. Hence it appears that about one-seventh of the whole mean resistance of such an accumulator is caused by the resistance of the lead lugs themselves; and that the resistance of such accumulators as we have been experimenting with can, when joined up in series, be increased by 25 per cent. if the contacts be allowed to become dirty by the acid spray falling on them, even although they remain all tightly screwed up.

Since these tests were made we have had all the accumulators disconnected, the contacts carefully cleaned and tightly screwed up, and the nuts and screws then coated with hot paraffin wax.

The coarsely divided paraffined cork which is sold by Messrs. Drake & Gorham for floating on the tops of accumulators to filter the hydrogen gas from sulphuric acid spray, was most successful in stopping the acid fumes from escaping into the room when we first obtained it. As, however, the cork became thoroughly wetted with the liquid, its filtering property was much diminished. It appears to us that there still remains the need for a really good spray arrester.

IV.

ANALYSIS OF PLUGS.

The following is the report of the analyses of the plugs removed at different stages of the charging and discharging, which Mr. Robertson has been so kind as to prepare for us:—

Report by G. H. Robertson on Analyses of Plugs from an E.P.S. Cell made in the Chemical Department of the Central Institution.

16th October, 1890.

Preparation of the samples for analysis:—

The positive samples were taken separately, washed on to filters, and thoroughly freed from acid. In every case the samples from the bottom were harder to wash than the others, and the residues were dried for some hours at about 120° C.

The samples were now ground up fine in an agate mortar, and the splinters of wood and glass removed as far as possible. The approximate weights for analysis were now taken and re-dried on watch glasses at about 140° C.

At first the substance for analysis was dissolved in a porcelain dish, and the insoluble residue of sulphate was filtered off with the intention of determining the amount of sulphate by the ammo-

nium acetate method; but owing to the small amount of material available and the error introduced by the solubility of lead sulphate in the nitric acid used to dissolve the sample, the attempt to determine both the peroxide and the sulphate was abandoned and the samples were used to determine the peroxide only as accurately as possible. This course was justified by the fact that very careful qualitative experiments showed that nothing but peroxide and sulphate was present in the plugs.

The method employed to determine the peroxide was the ammonium oxalate and permanganate method described in Sutton's "Volumetric Analysis," as in previous analyses it had been found very sensitive; and the solutions were checked about every two days against pure lead peroxide, and each day the solutions were run against each other, but they were not found to alter practically in the time they lasted. The first lot of ammonium oxalate was standardised against permanganate which had been very accurately standardised against iron, and by the nitrometer method.

Using this solution, "pure" lead peroxide, as purchased, and which afforded a slight white residue like silica, contained 97.3 per cent. as the mean of a large number of analyses made with different weights; and any subsequent solution which gave the percentage between 97.2 and 97.5, inclusive, was taken as correct. It will be noticed that d and A' gave practically the same percentage as the sample of pure lead peroxide.

The residues from the samples containing the highest percentage of peroxide of lead were white, those from the samples containing the smaller percentage were brownish-white; and it was noticed that if the larger grains were crushed under the end of a glass rod they had a dark centre of peroxide, which at once dissolved, leaving a slight yellowish-white insoluble ring. By grinding the sample very fine in the mortar, so as to break up the capsules of sulphate more thoroughly, the residue was got lighter in colour; and using a flask to boil the substance in, the residue becomes perfectly white: but this yellowish-brown tinge to the sulphate does not seem to be due to any appreciable quantity of undissolved peroxide, as practically identical percentages were obtained with pure white and yellowish residues. Dark residues gave low results.

In the case of the very hard plugs, there was some error from the glass and wood, which could not be picked out altogether, though the samples were picked over very carefully (cf. d', d'', e').

For the sake of comparison the percentage of Pb O<sub>2</sub> at A in the following table is taken as 47·9, as at c'.  
The calculations refer to the mean values of Pb O<sub>2</sub>, and the values of the P.D. before breaking circuit.

Charge.	Interval.	Increase per hour in percentage Pb O <sub>2</sub> .	Percentage increase in P.D. in interval.	Percentage Increase in Pb O <sub>2</sub> in interval.
	A to B B to C c to D	3·0 4·8 3·8	3·1 1·6 7·4	27·6 8·8 10·8
Discharge.	Interval.	Decrease per hour in percentage Pb O <sub>2</sub> .	Percentage decrease in P.D. in interval.	Percentage decrease in Pb O <sub>2</sub> . in interval.
	A' to B'	4·3	3·1	31·7
	B' to c'	3·6	5·4	15·3
	c' to d'	2·6	67·4	6·5
	d' to e'	1·6	100 0	5·4

The screening influence of lead sulphate is clearly brought out in this table. Between A and B the surface film and the coatings on the partially reduced granules of Pb O<sub>2</sub> are got rid of; then between B and C the pure lead sulphate is attacked; and finally, between C and D, with the removal of the last traces we get a very rapid rise in volts P.D.

In the case of the negative plates, the sulphate was in such a loose and powdery condition that it fell off and adhered to the insides of the bottles used for receiving the plugs in, and it was quite impossible to obtain representative samples for quantitative analysis; so qualitative tests had to be made, which in the case of charge, showed nothing but sulphate of lead and lead, the sulphate decreasing during charge until at D there was practically nothing but pure lead.  
During discharge the sulphate increased; at c' there was a doubtful indication of peroxide of lead, and at d' and e' there was decided evidence of peroxide. After a few days the plugs were white all over, and there was no difference in appearance between the front and back. The water had no acid reaction.

FIG. 7.

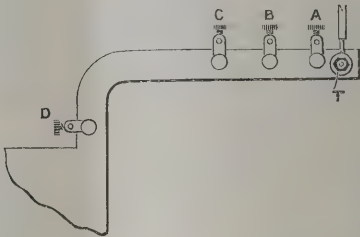

FIG. 8.

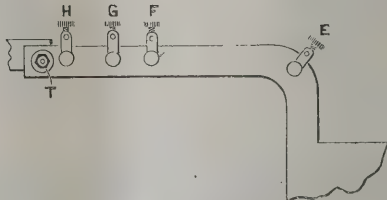

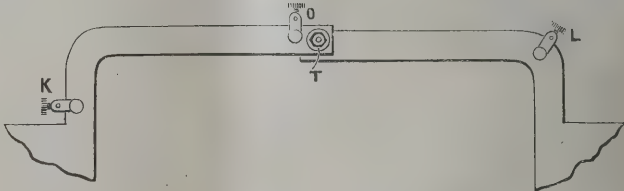

FIG. 9.

It will be observed that :—  
(a.) The particles of the peroxide very soon get coated in the discharge with a layer of lead sulphate, which protects the peroxide from further action, as shown by the examination of the dark-coloured residues which contained peroxide, and which were rendered very hard to dissolve by the coating of sulphate.  
(b.) The analysis also shows what a large proportion of active material is still remaining at the end of the discharge. This has been remarked on by many experimenters.  
(c.) The loose powdery surface of the positive plate seems to be thoroughly converted into lead sulphate. C and B' dissolved readily, leaving pure white residues.  
(d.) When the peroxide in the surface of the plate falls to about 31 per cent. the cell loses its E.M.F. very rapidly, owing to the inactive layer of sulphate impeding the action of the sulphuric acid on the active material behind it, and also to the formation of peroxide on the negatives. The diffusivity of the acid is decreasing, and it has to penetrate further into the plate to find active material. When the whole of the paste approaches this composition of 31 per cent. peroxide, the cell loses its E.M.F. entirely.  
(e.) The action seems to take place most rapidly where the current-density is greatest; the plate gets hard there from sulphate soonest on discharge, and oxidises quickest on charge.  
Planté and Messrs. Gladstone and Tribe have both noticed the formation of peroxide of lead on the negative plate during discharge, and pointed out that once it is formed more rapidly than it is reduced, the two plates must rapidly approach electrical equilibrium; that when the circuit is broken local action alone can take place, and this will reduce the peroxide on the negative plate, and on making the circuit again the cell will again give a current; and in this way Messrs. Gladstone and Tribe account for the resuscitating power of the cell, as well as for the rise of E.M.F. on breaking the discharging circuit.  
I have to acknowledge the facilities afforded me for seeing the plugs as they were removed, and the care taken to let me have the samples in good condition.  
I am also indebted to Professor Armstrong for his invaluable advice and assistance in the execution of the work.  
G. H. ROBERTSON.

From the mean results of the preceding analysis carried out by Mr. Robertson, we have drawn the curves seen in the lower part of figs 1 and 2, and which show the percentage of  $PbO_2$  found in the plugs of the positive plates at all stages of the charge and discharge. In the  $PbO_2$  curve for charge the first point is obtained from the analysis of the plugs at the end of the normal discharge—that is, when the terminal P.D. had fallen to 1.85 volts, indicated by the point  $c'$  in fig 2. The percentage of  $PbO_2$  actually found in the positive plugs at the point indicated by  $A$  (fig. 1) does not lie on the  $PbO_2$  curve as drawn, but, as already indicated, this arises from the specimens removed from the plugs at experiment  $A$  being only scrapings off the surface, and therefore not representing the average constitution of the plugs. On all subsequent occasions when specimens were removed from the plates, whole plugs, as already stated, were detached. The analysis at the point  $A$  (fig. 1) was, therefore, abnormal, and the percentage of  $PbO_2$  obtained for this point, and which is given in the table, is not indicated on the curve.

If the energy given out by the cell be produced by the conversion of  $PbO_2$  in the positive plugs, and of  $Pb$  in the negative, into lead sulphate, a constant value of the P.D. at the terminals of the cell when a constant current is passing through it ought to correspond with a constant rate of variation of the percentage of  $PbO_2$  in the positive plugs; so that for a constant current

$$\text{the terminal P.D. should } \propto \frac{d(PbO_2)}{dt},$$

$t$  representing time. This connection is seen to exist fairly well in the case of the discharge where the slope of the  $PbO_2$  curve is roughly constant as long as the P.D. is constant, and acquires a less inclination to the axis of time when the P.D. is rapidly falling. In the case of the charge, the connection between the value of the P.D. and the slope of the  $PbO_2$  curve is not so easily seen; but this arises from the fact that towards the end of the charging there is a rapid rise in the resistance of a cell, and therefore in the P.D. required to send a constant current through it; further, the back E.M.F. steadily increases during charging on account of the polarisation, which grows larger and larger from the continuous evolution of gas at the surface of the plates.

(To be continued.)

18409. "The improvement of electrical switches and other electrical apparatus." L. A. DAVIES. Dated November 15.

18412. "Improvements in electric batteries and lighters for cigars and other purposes." D. ROBERTSON. Dated November 15. (Complete.)

## ABSTRACTS

### OF PUBLISHED SPECIFICATIONS 1890.

350. "Improvements in the formation of electrodes for use in primary and secondary electric batteries." L. EPSTEIN. Dated January 8. 8d. Consists in dividing the process of manufacturing the electrodes into two separate parts, the first part being limited to the making of so-called raw electrodes, which are then transformed into positive electrodes, with the assistance of an electric current in an electrolyte, containing either diluted sulphuric acid, or a suitable salt of sulphuric acid, while the negative electrodes are formed by a reduction of the positive electrodes. 7 claims.

2199. "Improvements in cores and armatures for electro-magnets, solenoids, and the like." S. C. C. CURRIE. Dated February 11. 4d. Consists, firstly, in providing a core or armature of a compact mass of iron in granular form, such as iron chips, filings, or shavings, as described; consists, secondly, of a core or armature formed by mixing or combining with iron filings, chips, or shavings, an insulating substance or material in a granular or liquid condition, and then causing the same, after being subjected to pressure and drying, to assume a compact mass; and consists, thirdly, of a core or armature formed by mixing or combining with iron filings, chips, or shavings, an insulating substance or material as silicate of soda, in a granulated or finely divided state or condition. 10 claims.

2234. "Improvements in electro-mechanical movements, chiefly designed for regulating the carbons in electric arc lamps, and for similar purposes." S. E. NUTTING. Dated February 11. 8d. The object of this invention is to make an electro-mechanical

movement that will be proportioned at all times and under all circumstances to the quantity of the electric current, varying with every variation in the quantity of such current. 5 claims.

2464. "Improvements in electric light fittings." C. M. DORMAN and R. A. SMITH. Dated February 15. 6d. Consists partly of forming the metallic terminals of the lampholder and ceiling plate with a projecting hook round which the wire conveying current can be twisted; the weight of the fitting is then borne by these hooks instead of by the terminal screws. Also consists in using a novel form of spiral spring nut by which the reflector or shade is held on to the lampholder. Also consists in forming an independent cord-grip arrangement in the cover of the ceiling plate, consisting of a screwed nozzle through which the wires pass, which nozzle, when screwed home, squeezes the wires, which are led one on each side of a loose disc between the nozzle and the cover of the ceiling plate. 5 claims.

2621. "Improvements in electrically driven fans." H. G. WATEL. Dated February 18. 6d. Consists in applying the electrical driving near the centre of the fan, accommodating the electro-dynamic apparatus within a hollow boss. 1 claim.

2825. "Improvements in bases, covers, and fixings for electrical safety fuses, switches, and the like." W. WHITE. Dated February 21. 6d. Relates to means of making attachments and fixings to ceramic material.

2957. "Improvements in electric counters or apparatus for ascertaining and registering the duration of the passage of an electric current." J. J. A. AUBERT. Dated February 24. 6d. Consists of a clockwork movement, the pendulum of which is governed by an electro-magnet or a solenoid, which is in communication with the conductor of electricity. When the current passes, the clockwork movement is put in motion, but when the current is interrupted the pendulum encounters an obstacle which stops the clockwork. If the face of the clockwork is provided with a suitable scale and pointers, the exact time during which an electric current has passed will thus be registered. 3 claims.

3024. "Improvements in electric-motors." H. H. LAKE. (Communicated from abroad by E. B. Parkhurst, of America.) Dated February 25. 11d. Comprises multiple magnets or coils in the field and armature, one or both of which are revolved, and groups of magnets or coils in the armature are successively caused to act in conjunction with groups of magnets or coils in the field, when the respective poles of the groups of magnets or coils are so related to each other as to produce a maximum result from the current employed. 7 claims.

3924. "Improvements in electric Batteries." H. H. LAKE. (Communicated from abroad by the Crosby Electric Company, of New York.) Dated March 12. 6d. Consists in certain novel features, the object being to produce a simpler, cheaper, and more effective device than is now in ordinary use. 4 claims.

## THE FRENCH TELEGRAPH AND TELEPHONE BUDGET.

THE discussion on the above portion of the French Budget was sufficiently acrimonious, but if possible our Parisian contemporaries' comments were more so. To take one, for instance: The discussion on the Budget of Posts and Telegraphs permitted the Chamber to clearly manifest its approbation for the system set forth by M. de Lanessan and some others, a system which consists in treating the postal service as a well administered service, that is to say, in reserving a small portion of its profits to improve the position of its staff and develop its material, in obedience to the growing requirements of the traffic. From the new studies to which the Government and the Budget Commission have undertaken, a new scheme has come forth, which the commission defends to-day before the Chamber, and which increases by 2,200,000 francs in receipts and expenses the postal budget of 1891. The 2,200,000 francs of expenses are composed as follows: At Paris, creation of two new offices and the employment of 100 postmen; and for the departments, among other things, the creation of 100 *petits télégraphistes*, unification of the kilometric indemnity of telegraph messengers to 7½ centimes; creation of telegraph offices, prolongation of the daily service in 13 offices, the establishment of 1,000 kilomètres of new wire, and an increase of 1,415,000 francs in the payment of the staff. But the sum of 2,200,000 francs only applies to the year 1891. The Minister himself declares that in order to carry out the programme of improvements necessary, much greater expenses will have to be met. He will set them forth in the budget project for 1892, which will shortly be laid on the table. Where are the 2,200,000

francs to be found for 1891? The Government and the commission propose to find them as follows: In the first place, they alter Article 6 of the law of April 5th, 1879, so as to place a tax of 0.10 on valuables of all kinds confided to the Post Office for recovery and remaining unpaid. Then they alter Article 5 of the law of April 6th, 1878, in such a way as to raise by 0.1 the tax on all printed matter over 20 grammes (other than electoral circulars, voting bulletins, newspapers, and periodical publications). The tax would thus be 0.02 up to 5 grammes, 0.03 from 5 to 10 grammes, 0.04 from 10 to 15 grammes, 0.05 from 15 to 50 grammes. To these proposals two amendments were presented. M. Mir asked that the expense should be raised to 2,500,000 francs, so that 300,000 francs might be given to the ambulant service.

M. Leydet wished to have the expenses raised to 3,000,000 francs, thus providing 300,000 francs for the ambulants, 100,000 francs for the principal receiving office, and 400,000 francs for the Parisian Telegraphic Service. But the authors of the amendments, while increasing the expenses, do not approve the measures proposed for the receipts. They regarded them as new taxes, and fatal on industry and commerce. It was from the profits of the working that they wished to deduct the cost of the improvements. M. Peytral, on the other hand, contended that before voting increased expenses, it would be necessary to ratify the increase of the correlative receipts. This objection, however, did not hold, and the President of the Budget Commission easily defeated it, because, at all times, Parliaments have voted public expenses before establishing taxes to meet them. On the contrary, the State determines its needs before knowing its resources. The Mir and Peytral amendments were rejected by 316 votes against 182 votes, and the expenses proposition of the Commission adopted. An amendment by M. Poulié, proposing an increase of 20,000 francs for the transformation of some single offices into compound, was also rejected. Regarding Corsica, M. de Douville-Mailefen informed us that while the postal service between Dover and Calais worked admirably for 100,000 francs per year, that between Nice and Corsica cost 350,000 francs, and worked when it pleased the concessionaires.

The Telephone Budget was voted without any observations of interest.

## CORRESPONDENCE.

### Electro-Deposition of Copper: Misconceptions and Fundamental Laws.

I notice that your contemporary, the New York *Electrical Engineer*, in its issue of the 12th ult., gives a leader in which it professes to "set at rights" certain "obvious miscalculations" put forward editorially in your paper. Without particularly referring to the degree of success with which its proposed task has been accomplished, I may perhaps be allowed to say, generally, that the article in question, and also certain passages in your own correspondence columns, suggest the prevalence of misconceptions which may perhaps be entirely removable by a simple reference to some of the fundamental laws of electrolysis.

One of these misconceptions (a) is that it is not permissible to assume, in the abstract consideration of a given case of electro-deposition, that the operation is carried on in one tank, instead of in several or many tanks, having in the aggregate the same extent of anode and cathode surface.

Another misconception (b) is that it is unjustifiable, because necessarily unfair and detrimental to a process for the electro-deposition of copper, to assume in a given case that the action takes place under a potential difference of one volt.

A third misconception ( $a_1$ ), which is involved in (a),

is that a current of (say) 3,000 ampères, depositing a given mass of copper in a given time, must necessarily give a result superior in point of economy to that obtained with a current of (say) 110,625 ampères depositing the same mass of copper in the same time.

It would, of course, be a very grave misconception to suppose that any results at variance with the well-understood fundamental laws and quantitative data of electrolysis can be obtained in practice.

The fundamental expression for electrical energy or work is

$$Q E,$$

in which  $Q$  is quantity of electricity and  $E$  electromotive force.

To dissolve and to deposit electrolytically a given mass of copper, some amount of electrical energy is required, and must be expended in performing electrical work. This amount of energy, however, is variable within wide limits. The main object of the art of electro-deposition is to determine in practice what amount of electrical energy it is most profitable to expend in producing a given result, *e.g.*, in depositing the given mass of copper.

The above expression for electrical energy may conveniently be rendered as

$$C E \theta,$$

in which  $C$  is current and  $\theta$  time.

Now although this value, as a whole, bears no definite relation to a given mass of (say) copper to be deposited, it involves one product, *viz.*,  $C \theta = Q$ , which, in the case of one depositing cell or tank, or any number of cells or tanks in parallel, is absolutely definite and constant in relation to the given mass. This fact is expressed in the statement that if  $C = 1$  ampère, and  $\theta = 1$  second, the mass of copper deposited will be neither more nor less than .0050478 grain.

It may here be observed that, in circuits containing no counter-electromotive force, the above value,  $C E \theta$ , may be equated to :

$$C^2 R \theta = \frac{E^2}{R} \theta,$$

where  $R$  is the resistance of the circuit.

But, in the contrary case, when  $E$  is opposed by a back electromotive force,  $E_1$ , the total energy expended is expressed by  $C E \theta$ , whilst  $C^2 R \theta$  represents the energy converted into heat, and  $C E \theta - C^2 R \theta =$

$$C E_1 \theta = \frac{E_1^2}{R_1} \theta \quad (\text{where } R_1 \text{ is the resistance associated}$$

with  $E_1$ ), represents the energy rendered potential in the products of the electrolysis. And it may further be observed that in the case of copper dissolved from and deposited upon copper, the back E.M.F. is so inconsiderable, at least when electro-deposition takes place under a potential difference approaching 1 volt, that the circuit may, practically, be considered as one in which

$$C E \theta = C^2 R \theta = \frac{E^2}{R} \theta.$$

Now, suppose we have to consider a given case of electro-deposition in the abstract—to obtain some idea of the power, time and *matériel* which would be requisite to carry it into effect, under conditions susceptible of being modified according to the requirements of practice; the first thing we have to do is to determine the value  $C \theta = Q$ , which is dependent solely upon the nature and upon the mass, or weight, of metal to be dissolved and deposited. If time be given or assumed, we have only to calculate  $C$  from the datum given above. Now  $C$  is the current necessary to deposit, in the time  $\theta$ , the given weight of metal in one depositing cell or tank. Technically, this expression may mean any number ( $n$ ) of tanks, provided they are connected, not in series, but in parallel. Of course we are bound to assume the simplest conditions; nor is it necessary, as I will now show, to assume any other. If, instead of one cell or tank, there be  $n$  cells or tanks in parallel, these cells being similar to each other, and equivalent in the aggregate to the single cell assumed, then, of course, the current through any one of these will be

$c = \frac{C}{n}$  or  $n c = C$ . And if the  $n$  cells be arranged in series, exactly the same conditions will prevail; the current in any one of them will be  $c = \frac{C}{n}$ . In a concrete case this statement would not be accurate, because the dynamo giving the current would be constructed with a certain resistance, and to give a certain E.M.F. In such a case, it might be advantageous to arrange the tanks in multiple arc, or to connect them in series. M. Gramme, in his well-known experiments, found it advantageous to connect the tanks in series, simply because the dynamo he used was not one of low resistance. In our abstract consideration we are not tied, so far, to any stated E.M.F., or resistance outside of the depositing tanks; and it is absolutely indifferent, therefore, whether we determine to connect the tanks in parallel or in series. We can now obtain dynamos of very low resistance and economical in working, which was not the case at the period of M. Gramme's experiments. But even if this were not the case, it is not only allowable to assume the simplest conditions—that of a real or suppositious single tank—but it is not permissible to do otherwise in the absence of concrete data. Only an outsider would suppose for a moment that our data in relation to a single tank, from which other data can readily be obtained, were intended to imply, in case of extended operations, the construction of an enormous reservoir.

Our next step, to enable us to determine the energy to be expended in depositing the given mass of metal, is to fix a value for  $E$ . This value, in our abstract view, should be the potential difference of the electrodes in a single cell. Note that we have already determined  $C$ , which is the *ratio* of  $E$  to  $R$ . If in our equation we over-estimate  $E$ , from the point of view of economical working, we also in this equation over-estimate  $R$ . Thus, before anyone can fairly complain that too high a value has been assumed for  $E$ , he must have arrived at the conclusion that the corresponding

value for tank resistance ( $R$ ), *viz.*,  $\frac{E^2 \theta}{W} = \frac{W}{C^2 \theta}$ , is too

high for economical working, and that more capital should be invested in tank plant, and less money expended in electrical energy, than are indicated in the equation arrived at. In the case of a process in which the strong point is low tank resistance, a high value of  $E$  and of  $R$  might advantageously be challenged on the score of economy; but when the weak point of a process is high tank resistance (*vide* the penultimate paragraph in my letter on page 572), the suggestion of a high value for  $E$  might be unfair only in the sense of unduly favouring the process in question.

Having arrived at a value,  $W = C E \theta$ , applicable in the case of a single tank, or in that of the equivalent  $n$  tanks in parallel, we have data so readily applicable to the case in which the  $n$  tanks are in series that it is not necessary in general to specially refer to this case. The resistance of the "single tank" being  $R$ , that of each of the  $n$  tanks will of course be  $n R$ , and that of the  $n$  tanks in series will be  $n^2 R$ . Now to obtain the original current passing between unit anode and cathode surface, we require a potential difference equal to  $E$  acting over each tank, or  $n E$  for the  $n$  tanks in series. This current

will obviously be  $c = \frac{n E}{n^2 R} = \frac{E}{n R}$ , and the electrical en-

ergy expended in the time  $\theta$  will be  $n E \times \frac{E}{n R} \theta = \frac{E^2}{R} \theta$

$= C E \theta$ , as before. To assume that there is essentially

any advantage in reducing the current from  $C$  to  $\frac{C}{n}$ ,

when the electromotive force is augmented from  $E$  to  $n E$ , and that the mere indication of this reduction of the current is a crushing rejoinder to those who may calculate current on the "single tank" basis is a misconception, that to be refuted needs only to be pointed out.

Desmond G. FitzGerald.

### Telephone and Telegraph Construction—A Pole for Many Angles.

As I have not seen nor heard during my 20 years' experience in telegraph construction of a really good improvement in the arming of poles for positions where the angles, acute or obtuse, cannot easily be avoided, I beg to submit a rough sketch of a novel arrangement which may be useful to, and improved by, electrical engineers.

The objects and advantages are as follows, viz. :—

1. To dispense with G.P. cross connections and to admit of the line wires being run through in a similar manner to the ordinary poles.
2. To lessen complications on terminal poles.
3. To suit all, or many, angles by simply fitting the arms on the iron supports to face the pole on each side of the span.
4. To keep the wires the same distance apart as the holes in the arms, and thereby lessen the risk of contacts in stormy weather, &c.

A square pole, or two round poles fitted together in the form of the letter A or H, might be employed to

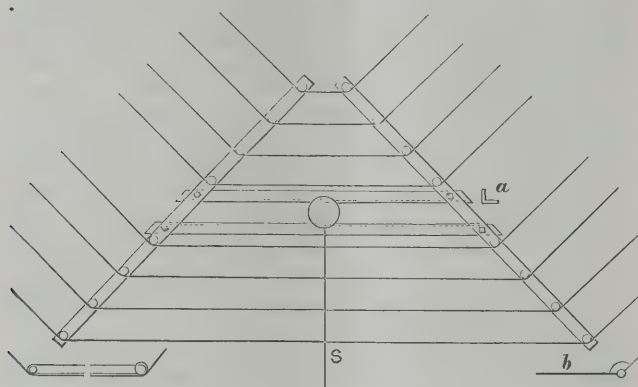

FIG. 3.

FIG. 1.

FIG. 2.

Scale  $\frac{1}{4}$  in. = 1 foot.

a, Section of iron; b, Thick wire to act as stay; s, Stay.

advantage in exposed positions. It would be advisable to terminate all the wires as shown by fig. 2 (the groove will admit of this in many cases) on account of the undue strain at the insulators, and to have two inner wires at both ends of the arms of a larger gauge to act as a brace; or the arrangement shown by fig. 3 might be preferable.

When the pole is to act as a terminal pole the arms would of course be braced together in a similar manner to fig. 2, but, say, under the shoulder of the insulator bolt.

I will say nothing about staying, but simply show a stay.

A. I. E. E.

November 26th, 1890.

### Improvements in Telephone Switchboards.

With your permission I will reply to the letter of the Telegraph Manufacturing Company in yesterday's REVIEW.

In my communication which you published on October 31st, I showed that the advantages claimed, including the supposed saving of 30 per cent. in operating, did not exist, but that on the contrary there was a loss, though I did not presume to define it in percentages, the careless use of which on mere estimates should be discouraged. But recognising, as I do, the many considerations which may determine the type of switchboard to be adopted, I assumed there might be some advantages not stated in the original article. In the letter now under reply, those advantages are stated to be accessibility for adjustment and repair, and certainty of action of the indicator drops.

The most delicate parts of a switchboard are the indicator drops. The illustrations on page 488 (October 24th) show the drops in front with three rows of plugs behind them. The back view (fig. 2) shows the cords between the mechanic and the drops. In the board shown in my article the drops are within a few

inches of the mechanic, and there is no obstruction whatever in the way. In this respect, therefore, the exact contrary must be read. The "improved" boards in the most vital part are not more accessible, but less so. But too much importance must not be attached to this. The inaccessibility is not a serious drawback; it might well be submitted to if an increase in facility of operating is thereby attained, but there is no such increased facility.

The "certainty of action of the indicator drops" must be limited by the remarks in the original description, in which it was stated that they were "found to act perfectly well for all telephone lines of ordinary length"—a limitation which is not usually considered an advantage, any more than a reduction of their sensitiveness contributes to increasing the certainty of their action.

The letter further says that I have fallen into the error of assuming that the board shown is the only pattern made. That is not so. The description stated that the board was a standard pattern for any number of lines from 25 up to 150. I took this to mean that an exchange starting with 25 lines would put in a 30-line board, which would form a convenient unit for additions up to 150. This meaning appears clearly from my words, "by the time the exchange had reached." I see that the words in the original description are capable of another reading, but my error arises from having reasonable conditions in mind. The modification changes the ground, but, unfortunately, this is one of those subjects which will not permit one to change one's ground without encountering a further set of conditions for consideration. A unit of 30 is small, but one of 150 is larger than is generally considered economical for small exchanges. To add smaller boards which do not match the first does not commend itself, and to change complete switchboards of small number for complete switchboards of a larger number as the subscribers increase, though possible to large companies with a number of exchanges, is expensive, and more serious to smaller companies whose exchanges are limited in number, or distant from each other.

Then the letter states that if the small pattern annunciators are adopted, "the s. c. board will be quite as compact" as that illustrated in my article. I enclose photograph of several "s. c. boards," on inspection of which you will doubtless appreciate the remark I made, but which the Telegraph Manufacturing Company overlook. I wrote: "I would like to point out that it is not necessary to cover so large a space. The boards may be more compressed, but then the plugs are crowded. It is a choice of evils." The photograph shows 50-line boards of the same width as the 100-line board illustrated October 31st, except that the framework is narrower, they are thus about one-half as compact. To appreciate what equal compactness means, it is only necessary to refer to the illustration, page 523 (October 31st), and add to the 40 plugs there shown 60 other plugs.

I do not see that there is any necessity to "assume" the correctness of the lists of movements I gave. Mine is correct. The other is taken verbatim from the full description of the "improved" board. Comparison is made between the similar number of movements on the one board with speaking keys, and the other without, as if there were still some advantage in that. But it is the absence of these keys (or their equivalent) which is the cause of the clumsy working which I pointed out. More especially is this the case when the operations are carried beyond the mere connecting and disconnecting, which is as far as the comparison has yet gone. The extra plugs and their attachments which become necessary on the "improved" board (which works badly) are more expensive in first cost and maintenance than the speaking keys on the other board (which works well).

Then, with regard to the single-cord boards with speaking keys, allowing four movements in all, which are compared with the board giving seven movements. The Exchanges at Dewsbury and Greenock since August, 1888, and Blackburn since March, 1889 (I

omit instances of earlier date in other countries), have been provided with single-cord boards necessitating only four movements. The principle is well known to telephone engineers, and has been the subject of very able criticisms and reports, which have been published. A 200-line board is about 6 feet long. I am not aware that any other than multiple boards have been made upon this plan, but as the greater includes the less, it could be done if it were considered desirable. Taking the basis of equal compactness with the board on page 523, it is only necessary to add 60 more plugs to the 40 that are there, and 80 more speaking keys (or their equivalent) to the 20 that are there, and one of the reasons why it has not been done may become apparent. Supposing such a board to be made, what becomes of the simplicity and accessibility, not to mention economy, which are rightly (within reason) taken as desirable attributes of switchboards for small exchanges?

It would be affectation for me to overlook that some inference is intended to be conveyed by the reference to my communication as "criticisms by the Western Electric Company through Mr. Kingsbury." If it is intended to be implied that I sent to you, under my own name, a communication which had been prepared by others, you will perhaps permit me to say that the implication is both incorrect and unnecessary.

I am not authorised to criticise on behalf of my company, nor do I wish my remarks to bear the importance which the well-known experience of the Western Electric Company gives to their opinions on this and kindred subjects. I may say further that, in sending you a communication on a subject of general interest, it was not my intention either to advertise my own Company's manufactures or decry those of others. I have throughout confined my criticisms to the particular type of board described on October 24th, which may be manufactured by anybody who cares to take the responsibility of recommending its use, or whose customers in possession of all the information on the subject prefer to have it.

Descriptions communicated to the press are open to public criticism, and the area of critics should include all who can contribute useful information. To criticise on frivolous grounds is objectionable, but in glaring instances of a misleading character, it becomes a duty, especially so in the case of a subject which needs something more than superficial observation. Since the publication of the Telegraph Manufacturing Company's letter, there is no room for doubt that my criticisms were fair and accurate, in which case their origin, though it was frankly stated, is not material.

I do not know that I should have troubled you with those criticisms, but for the fact that I found the enduring work of far-sighted pioneers (some of whom are friends of mine) slightly referred to in comparison with a supposed improvement, the claims of which I examined. I thought the result of my examination of sufficient interest to send to you.

I am sorry this letter is so long. Unfortunately, it takes a long letter to correct the errors of statement and suggestion which may be crowded into a short one.

J. E. Kingsbury.

November 29th, 1890.

P.S.—Will you kindly note I have reverted to the original title. I do so because there are single cord boards and single cord boards.

#### Electric Light on Shipboard.

It must be gratifying to electrical engineers engaged in ship-lighting work to find that the matter is receiving the attention of the Institute of London Underwriters, and other authorities. It must be admitted by those engaged in the work that it was high time some uniform rules or regulations on the subject existed, and also that electric light installations on shipboard should come under survey and inspection; cheap and nasty installations would then be the exception instead of being almost the rule they are at present; and this

survey or inspection should not only be made on the completion of the installation but also at intervals thereafter. It is quite commonly the case to find some years after a ship has been fitted out that numbers of the lights have been shifted, new branches have been made in the wires, old ones left in connection, fuses rendered useless, being connected across by heavy wires and so on. These changes are mostly made by the engineers on board without the assistance or advice of any skilled electrician; consequently sometimes faults are introduced into what was at first a good installation. The inspection of all the fuses on board and of any new wires run in, or old ones disused, should be made frequently.

It seems to be imagined that the single-wire system is more likely to influence the compasses than the double-wire system: quite naturally one would think so, but practically it is such an easy matter to avoid any action on the compasses, that there in reality can be no preference for the one system over the other on that score. The compasses are fixed in certain positions; in almost every case far removed from the main single wires, and it is always arranged (or at least it ought to be) to have a main branch pass on either side of the compass, or run the branch near the compass double-wired. In every single-wired ship there are many places where double wires are run; no ship is entirely single-wired.

In so far as the danger to the compasses from magnetic leakage from the dynamos exists, it is equally the same whether the ship is double or single-wired.

The weak-spots in any ship installation are the joints (always granted, of course, that good wires are used throughout). In a ship with 300 lights, double-wired, there will be probably about 700 soldered joints, that means about 700 points in wiring where the original insulation is cut off and re-insulated by the workmen. Another weakness in double-wired ships lies in the fittings. In these double contact fittings two wires are pulled through, and connected to the holders by screws. In these fittings the wires may make contact with the fitting, or with each other.

In single wiring we have the advantages arising from the fewer joints and less total length of main wires required, and also the advantages of using single wired fittings end central contact holders, these being much safer than double wire fittings and double contact holders.

In a double-wired\* ship having 300 lights, there shall be about half the total length of wire and about half the number of joints. Now it is much easier maintaining the shorter wire in good order, and what is of greater importance, we can spend twice the amount of money on the insulation of the wire per yard, and we can spend twice the amount of money in making each joint. The making of thoroughly water-tight, reliable joints in a high-class insulated wire is a job one very seldom sees; it requires some skill, and therefore has to be paid for. The contractor who puts in single wiring can afford to put skill into his joints and first class wires and insulation into his installations; and, after all, these two points are the important ones in a ship installation—first class insulated wires and skillfully made joints—and, generally speaking, the less wire and fewer joints the better.

As to the accidents which sometimes occur, and *very nearly* originate a fire, these may arise from many causes on board a ship, quite apart from the nature of the wiring, that these cases have been made the occasion for making comparisons between English and American practice in American journals is to be regretted; but since they have been made, I may refer to them here. In the first place, the Americans are not a shipbuilding people, and have not had great opportunities of gaining experience in ship-lighting. I have seen their electric light wires and wiring, and on comparing them with the products of our leading makers on this side, come to the conclusion that we are consi-

\* This seems to contradict the previous par.; should it not read single-wired? —EDS. *ELEC. REV.*

derably better off than they are. A wire equal to the best of our vulcanised rubber insulated wires is not to be got on the other side. The lead-covered wire *without a continuous insulation* of vulcanised rubber is a failure on board ship. Sea water is certain to get in between the wire and the lead pipe where there is no rubber insulation. In fact, if it were not for their high import duty, it would be better for American contractors to import their wires for ship-lighting.

There are scores of large ships single-wired, which have been crossing and recrossing the Atlantic in all weathers, some of them to my knowledge for six years, without either a derangement of the compass or an approach to a fire, and I have no doubt that Messrs. Siemens Brothers could give many instances of single-wired ships fitted by them years ago, in which not the slightest trouble has occurred. And, simply on the score of safety, many of the petroleum ships are single-wired. I know of eight or ten of them which have been running with single wiring for three years past without trouble.

Rankin Kennedy.

#### Polarising Conditions in a Galvanic Battery.

On reading an article by Prof. Dolbear which appeared in the ELECTRICAL REVIEW of the 14th November, I was much struck by some statements he made, because they are in direct opposition to what I have been led to consider—on the authority of one of our ablest electricians—to be the fundamental laws of voltaic electricity.

Prof. Dolbear says in his article, "When a piece of zinc is immersed in water it is found to be electrified, and its potential may be measured by a suitable electrometer;" and again, further on, "When a piece of carbon, or copper, or other element is placed in water, it exhibits similar electrical property." Now, is this the case? For is it not to "Volta" that we owe the discovery of a potential difference being set up, "at the point of contact," of two dissimilar metals?"

Surely, then, it follows from this, that by immersing either of the metals singly or together (but in this latter case not touching or connected in any way other than by the liquid), no potential difference is set up. At least, none adequate enough to account for the E.M.F. of the couple. When, however, one of these is brought into contact with the other, or with "any" dissimilar metal, *e.g.*, a gold ring, then a potential difference is immediately established. Being at present a young electrician, I am merely anxious to know how to reconcile these two diverse views, and I should be very glad if any of your readers would kindly inform me.

A. E. Gosset-Tanner.

November 29th, 1890.

[There is a considerable difference of opinion as to the real seat of electromotive force in the galvanic cell, but a single metal in contact with a liquid becomes polarised. "When a single metal is placed in contact with an electrolyte, a definite difference of potential is produced between the liquid and the metal. If zinc be plunged into water the zinc becomes negative, the water positive. Copper plunged into water also becomes negative, but much less so than zinc." (Jenkin's "Electricity and Magnetism," page 44.) We recommend you to study Chapter II. on "Potential," of Jenkin's book, from which the foregoing extract is taken.—EDS. ELEC. REV.].

#### Notes on Electric Lighting from Central Stations.

Herewith I enclose you for publication copy of letter received by me last week, dealing with statements made in my paper read before the Liverpool Engineering Society.

In putting this before you, I make no comment on the ideas held by the officials of the Silvertown Company, beyond that the data given by me was obtained on the spot, and that in each case I did my best

to verify the statements attributed to me. We are all well aware of the success attending the underground system at Hastings, and it certainly reflects great credit, not only on the manufacturer of the cables in use there, but also on the engineers of the station, Mr. Mercer and his colleagues, that such exemption from troubles on the line has been obtained. With reference to high tension cables, I see no reason why cables insulated with material other than vulcanised rubber should not be equally fit to withstand the stresses brought to bear on the dielectric, and have reliable data to the effect that Messrs. Felten and Guillaume have had some cables of special make under 10,000 volts for some time with perfect success. The Fowler-Waring Company are perfectly able to reply to any remark passed on their manufactures.

In reply to the Silvertown Company's query as to Callender cables, I simply stated that the Liverpool mains under the low tension in use here have proved most successful, and have, under adverse circumstances, maintained their high insulation. I am informed that at Batu a length of over five miles of Callender main has tested up to 50 megohms, and withstands easily 2,000 volts. I prefer to allow the engineers of the Liverpool Company to make more definite statements.

Charles H. Yeaman.

December 1st, 1890.

[COPY.]

The India-Rubber, Gutta-Percha, and Telegraph Works Company, Limited, 54, Castle Street, Liverpool,  
27th November, 1890.

C. H. Yeaman, Esq., Liverpool.

Dear Sir,—We are instructed by our London house to draw your attention to an article in the ELECTRICAL REVIEW, dated 21st inst., entitled "Notes on Central Station Electric Lighting," being a paper read by you in January last, before the Liverpool Engineering Society.

We have to point out that certain statements made therein are inaccurate. We are not asking that you should correct these publicly, but we write you that there may be no misunderstanding in future.

You only refer occasionally in the paper mentioned to underground cables, but in three of your references you are wrong.

In the first you say that all underground cables at Hastings are G.P. covered. About one-half are vulcanised rubber insulated cables supplied by us, and we understand that all future extensions will be carried out with this type of our Silvertown cable.

The Hastings Company write us, under date of July this year, "We have pleasure to report the success of the cable supplied by you to our company since the early part of 1884. Although we have several miles of your cable through iron pipes, corroded by the action of the sea and rain water, we have never had a fault, and there is no noticeable depreciation in the insulation resistance of 600 megohms per mile. The cables have been used for high tension currents connected to Brush machines at pressures from 1,500 to 2,000 volts."

At West Brompton, the Fowler-Waring cables on trial there have been abandoned, and our vulcanised rubber cables are exclusively used. With regard to the further statement that Mr. Ferranti has found that the Fowler-Waring cables are the only ones that will stand 10,000 volts pressure, a similar statement was made in a French paper, and we wrote to Mr. Ferranti, who replied to us as follows:—

"He certainly did not get the information from me that your cable broke down when tested with 10,000 volts. Certainly a number of cables did break down under varying pressures, and no cable was found which was sufficiently good electrically, and within the bounds of possibility commercially. Still, he should have mentioned that I applied to the Silvertown manufacturers, and did not receive which I wanted from them. I very much regret the trouble this has given you."

We believe the Fowler-Waring cables have been condemned the reason Mr. Ferranti did not order the 10,000-volts cable from us is that he did not consider that they were within the bounds of possibility, commercially.

In this we cannot agree with him until he produces, at a lower price, a cable that will work as successfully at this pressure as our own would.

As you are the City Electrical Engineer for Liverpool, we think we should put the above before you, and we beg to ask (as you appear to think highly of the Fowler-Waring cable), what is your experience with "Callender" cables?

Awaiting the favour of your reply,

We are, dear Sir,

Yours faithfully,

(Signed)

R. T. CURRIE.  
For the Company.

CYCLES.

THERE are those who maintain that what happens to-day has happened before and will happen again, and that the periodic recurrence of an event may be defined with an accuracy almost approaching to the determinations of the exact sciences. All that is necessary is to ascertain the duration of its cycle. In the branch of natural phenomena we are told of the number of years which may be expected to elapse before one great storm will be followed by another. Experts in their respective branches prognosticate without any reserve the date of the next great financial crisis, or the re-appearance of African lions in London drawing-rooms. To scientific cycle-ists (we adopt this spelling to distinguish them from the bi-, tri-, and electric- varieties) the progress of the Salvation Army in this decade, and the propagation of General Booth's scheme in the present year, are easily explainable by the law of recurring intervals applied to religion and philanthropy. Such a law in politics is generally recognised, though careful exponents of the science who are at all jealous of their prophetic reputation, are generally a little vague in their assertions in this department. Political events, like comets, sometimes become wrecked among satellites, their progress retarded, and their cycles disturbed. In the department of History there are two sub-sections—(A) dealing with cases in which history repeats itself, and (B) with cases in which it is repeated by others. In sub-section (B) is included the science of the cycles governing the rediscovery or revival of practical inventions and their supposed anticipation.

We have been partially converted to the views of the cycle-ists. When conversion once begins, there is no knowing where it will end; but, at present, we only pin our faith to the application of the science in the department of History, sub-section (B). By careful study we have acquired such proficiency that we have no hesitation in commencing our public exposition of the science by predicting the revival of the Bourseul

telephone project in from eight to ten years' time. We do not put this suggestion forward on mere guesswork but on scientific principles. We have discovered the circumference of its cycle.

When Mr. Latimer Clark kindly sent us the Bourseul article the other day we did not insert it, but remarked that all the information on the subject was well known. Yet it has gone the rounds of the electrical press with all the interest attaching to new material. Our contemporaries, wiser than ourselves, did not overlook the incidence of the law of recurring intervals, and the result of it is we are weeks behind, instead of being, as we fondly imagined, years ahead.

Regarding the matter from this point of view, we are bound to confess that the period which has now received scientific sanction, is a reasonable one. In intervals of ten years *Punch* might republish its obscure jokes and the *Daily Telegraph* its social leaders, except for the uncomfortable people whose mission in life it is to discover such coincidences and write to the editors of rival prints to announce their discovery. In earlier centuries the interval would have been longer, but now the storm is fiercer and the stress is greater; so much new material has to be assimilated, that it is excusable to forget the old. And, when the revival comes, there are many to whom the information is new, so that what with those who never knew, and those who knew and had forgotten that they did know, the interest in the subject is wide and general.

We now see that our apologies are due to Mr. Latimer Clark for not recognising that he was the instrument of the mystic power which controls the cycles, as well as to our readers for withholding information of a novel and interesting character. We make haste to amend. Our readers will please consider it has been recently discovered that back in the fifties "a certain M. Ch. Bourseul" conceived the idea of transmitting speech by means of a vibrating disc set in motion by the voice, and, coincident with its vibrations, making and breaking an electric circuit. A similar disc at the

receiving end was to undergo in the same time the same vibration, and speech be reproduced. Bourseul's idea was of telegraphic derivation, and its similarity in outline to the telephone has led to the suggestion that it need only have been submitted to practical experiment to have given us the telephone in '54 instead of '76. We thought it was known long ago, but our readers will please to again consider it has only recently been discovered, that speech would be impossible by the method suggested. The reason why we give below, in an extract from an exposition of the telephone for the general reader. We select this description, because it helps us out with our cycle theory by having permitted itself to be published in 1882. After remarking that in 1854 Count du Moncel referred to Bourseul's suggestion as a "fantastic idea," and in 1879 the same Count du Moncel published an account of the telephone which carried out the fantastic idea, the author says:—It will be observed, however, that the apparatus which he suggested would not be capable of transmitting speech. A vibrating disc, making and breaking an electric current, would enable a simple sound of a certain number of vibrations to be reproduced, but would not be sufficient for the transmission of speech. M. Bourseul did not overlook the complex nature of the sounds of the human voice, but in his paper referred to, failed to suggest any practical means for their electric transmission. Professor Bell claims to have been the first to utilise the "undulatory current" which made the transmission of speech possible. A disc connected with a battery and vibrating against a wire would enable an electric current of definite strength to be sent through the wire a certain number of times in a given period; but the speaking telephone admits of the sending through the wire a current that is not always of the same strength, but whose intensity varies or "undulates," and so is capable of far greater variety than the mere make and break.

## THE ELECTRIC CONSTRUCTION CORPORATION, LIMITED.

THE vulgar refrain, "It's wonderful how they do it, but they do," has been ringing in our heads ever since we read the report and balance-sheet of one of the large electrical companies the other day. But light has broken upon our benighted minds, for the *Oracle* (see another page) has spoken. Oracles are usually ambiguous—not so the daily of that name in its article of the 8th inst. It points out that the very important item of £128,117 in the balance-sheet of the Electric Construction Corporation represents shares in subsidiary companies at par, shares included in the original purchase at nominal value, and debts due by subsidiary companies. It then proceeds to dissect the subsidiary companies, and throws doubt on the par value of their shares. The companies mentioned are the Foreign and Colonial

Electrical Power Storage Company and the Electrical Construction and Maintenance Company. As the profit and loss account of the E.C.C. is based on this valuation, it suggests that the directors have not been discreet in reckoning the profit at the figure they have done.

The same idea has occurred to others. As the *Oracle* says, the directors are very able men, and we will add the suggestion that had they been able to convert the mass of paper they hold into sterling, they would doubtless have done so. If the value of a thing is what it will fetch, and these shares have not fetched par, it is reasonable to conclude that they are not worth it. No allusion is made in the article under review to the Electric Traction Syndicate, who paid heavily for promotion, and the right to use E.P.S. cells; and so we suppose we must not class the undertaking as a subsidiary company. Perhaps it is better than a subsidiary company, as it is reported to have disgorged cash, and not paper. So much the better for the Construction Corporation, and worse for the Traction Company. There is one other item to which our contemporary does not call attention—the cash balance. Perhaps they thought it was borrowed for the occasion, or hired, to speak more correctly—a kind of dress-coat in which to appear at the general meeting.

We have known men who never had a cash balance, unless they had raised it on loan, and whose only assets consisted of pawn-tickets. But companies are obliged to have their accounts audited, which is a good thing—especially for the auditors.

Some years ago, at a meeting of the old E.P.S. Company, when the younger brother of this balance-sheet was presented, and a paper profit shown, a shareholder, on asking why the profit would not be divided, was met by the chairman, who, with his usual directness, naïvely replied, "Because we haven't got it." They have it now—somehow, and are going to divide it.

We note that the Construction Corporation has taken up the Ward Omnibus business, and rumour credits it with a third of the City lighting, so it will soon have its hands full, and we sincerely hope its large works at Bushbury, not forgetting Millwall, too, likewise its coffers, for they will have to bear a strain under which paper might give way. We hope they will prosper in the good time coming—the electrical sweet by-and-bye.

Premature  
Announcements.

NOTHING depreciates the value of an invention, or application thereof, or lessens the confidence of the public, more than premature announcements of what is intended to be done. Yet for months and months has a contemporary stated that "in a few weeks" electric omnibuses will be plying on London streets, whilst a short time ago a representative of our contemporary stated that he saw one of the "new 'buses" carrying passengers. That statement was not only erroneous but the chairman of the Ward Electrical Car Company, at the meeting last week, actually said that the details of the contract for the first line of omnibuses had only just been settled.

Electric Lighting  
Difficulties.

EVERYBODY will sympathise with M. S. Z. de Ferranti in his trouble caused by the fire at the Grosvenor Station, even though they may not believe in his system. The complaints regarding the interruption in the supply of light have been so numerous that some customers have regretted having become clients of the London Electric Supply Corporation. The serious and second interruption last week might have been avoided had the "Festina lente" policy been pursued, instead of hastily repairing partially-destroyed converters, and putting up new transformers in a temporary manner.

Accumulator  
Traction.

IF the announcement be true that the E.P.S. cells can be maintained at a cost of one penny per car mile for 50 cars for traction purposes, storage battery traction should receive a great impetus in this country. The accumulator cars on the Barking line would probably have been remunerative to the General Electric Power and Traction Company had the depreciation been covered by one penny per car mile, and if the cars had been operated in a district where plenty of passengers is the rule and not the exception.

A Broker's View.

THE gradually increasing interest shown in the application of electricity to tramway traction is exemplified in the December report of Mr. W. W. Duncan, who is a well-known authority on tramway matters. Says Mr. Duncan:—"There is always the very important offchance—I look upon it as a certainty before long—of electricity as a motive power largely reducing the working expenses. It is already doing this in a very marked degree in America, where it is adopted in nearly all the towns and cities which I visited; but the system most in use is that of overhead wires, which is entirely unsuited to our country. I applaud the administration of our tramways for being in no hurry, and carefully avoiding anything experimental, but once they are satisfied, and I think the time is coming near when they will be, there will be a complete revolution in tramway affairs, and I trust my clients and I will be in at the feast of fat things."

Electric Traction  
Data.

WE shall publish in a future issue a paper recently read at the Chicago Electric Club by Mr. T. P. Bailey. Mr. Bailey furnishes data of operating expenses for one particular road carrying 20 electric cars. These are stated to be a little over six cents or three pence per car mile, and doubtless include repairs and depreciation. The author refers to the fact that there are still some complaints of excessive cost for repairs and maintenance of the electrical apparatus, but he insists that the responsibility for this condition does not altogether rest with the manufacturers. The managers of electric roads are exacting a greater mileage duty than is expected of the ordinary railroad steam engine and under conditions much more unfavourable. If they would see that their tracks are in good order, and the same care and attention given to the electric motor that is given to the steam engine, they will have little to complain of. "How rarely," exclaims the author, "do you find an electric motor operated on a track like that prepared for the steam engine? And how seldom do

you find a man in charge of the motor who has the intelligence, training and experience of the steam engineer?" We are fully in accord with Mr. Bailey, and we do not hesitate in predicting that the future success of electric railways will be due as much to skilful manipulation as to good design. Mr. Reckenzaun, in his paper on "Electric Traction Data," has shown that the same driver could, after he had acquired the necessary experience, under precisely similar conditions save 25 per cent. of the energy, and it was suggested at the time that comparative power tests should be made with the purpose of ascertaining the skill of the operator. Accidents to motors, switches and gearing will be reduced in a similar ratio by ordinary care and experience combined with that intelligence which the position of a driver demands, but without which no man should be allowed to assume the responsibility.

A Disclaimer

IT is with much pleasure that we insert the letter of Mr. A. W. Stokes on the subject of his report on Count Mattei's coloured electricities. Our correspondent holds certificates from Professors E. Frankland, J. Percy, F. Guthrie and several others, and his own letter will show how a report, which may have been scientifically accurate, can be garbled in the hands of interested or ignorant parties. Probably Mr. Stokes does not know how long and earnestly we have striven in all directions to put down electropathic quackery, but thanks to the aid it receives from the daily press it still flourishes.

British Insulated  
Wire Co.'s Cable.

WE have received a report by Mr. Charles H. Yeaman, electrical engineer to the Liverpool Corporation, with reference to tests of samples of this cable. The report is decidedly full, but we miss several very important details. We are told, for instance, the manufacturer's number of the galvanometer and other instruments used in making the test, but nothing is said about the quality of oil used in the galvanometer lamp, nor are we informed by whom the terminal connecting screws were supplied, nor whether the emery paper used for cleaning the wire connections was supplied by Messrs. Oakley—its degree of coarseness is not even given. But, seriously, we have seldom, if ever, read a report of a more absurdly bombastic much-ado-about-nothing character, and though we have no reason to doubt the correctness of the tests, the whole of the letter might have been given in a few lines. Of the value of the tests it is difficult to judge from the insufficiency of information. It is not stated, for example, whether all the cables were lead-covered; if they were, the statement that the insulation of a certain cable kept in the rain for 10 days was good owing to the "impregnation during manufacture with a heavy oil" is absurd, it is simply due to the soundness of the lead-covering, a soundness which is nothing remarkable. The only test made of the moisture resisting properties of the insulated material appears to be that of a piece of electric light cable *two yards* long with the lead stripped off soaked in water for 24 hours, a test which, of itself, is insufficient to be conclusive. We do not say that the cable is not good, but as yet, we have heard of nothing which indicates that it is better than that of other manufacturers.

**ELECTRIC LIGHTING AND TRANSMISSION  
OF POWER IN ITALY.**

AN important installation for the transmission of electrical energy for lighting and motive power purposes is now being carried out by the Italian Edison Company, near Intra, in Italy, for Mr. Carlo Sutermeister. This gentleman has a concession of 840 effective H.P. situated near the latter town, which is about six miles distant from Pallanza. The fall of water is 135 feet, and the quantity about 440 gallons per minute. It is obtained from a canal which is fed from the S. Bernardino river, near Cassagno, and runs for some distance in tunnels. The installation, when completed, will comprise four Girard turbines, each of 150 H.P., and each being coupled direct to a dynamo having an output of 96,000 watts (32 ampères at 3,000 volts), and an exciter of 4,000 watts capacity (40 ampères at 100 volts), and one Jonval turbine of 150 H.P., which also actuates an alternator and exciter of the same capacity. The turbines are fitted with an automatic regulator recently designed by Messrs. Ganz & Co. The plant will be used for supplying light and power to Intra, Pallanza, and neighbouring districts. The considerable distance between the generating and distributing stations rendered it necessary to use the same conductor for transmitting energy for both lighting and power purposes. The Edison Company therefore adopted the alternators, turbines and motors made by Messrs. Ganz & Co., of Buda Pesth, whilst the remaining electrical apparatus—transformers, lamps, meters, &c., are being supplied by the former company. The conductor, which is of bare copper wire, is being carried overhead on oil insulators, attached to standards, and the loss in transmission from one station to the other is estimated at 10 per cent. The efficiency of the turbines is guaranteed to be 75 per cent., of the alternators 88 per cent., and the transformers from 90 to 95 per cent. The motors will range from 3 to 50 H.P. Those from 3 to 20 H.P. will be energised from separate transformers, whilst the larger motors will receive current from the primary conductor at 3,000 volts, these motors being arranged in series. The current will be measured by Blathy wattmeters, and the installation is to be in full operation in March next.

**THE ELECTRIC LIGHT IN PARIS AND THE  
SMOKE DIFFICULTY.**

THE Council of Hygiene and Salubrity of the Seine last week appointed a committee composed of MM. Léon Colin (President of the Army Health Council), A. Gauthier (Professor of Chemistry to the Faculty of Medicine), Léon Faucher (Chief Powder and Saltpetre Engineer), Linder (Inspector-General of Mines), and Michel Lévy (Chief Engineer of Mines), to study the dangers of smoke from a hygienic point of view, and to prepare a scheme of regulation. It may be remembered that in June last the Council expressed the opinion, but in vain, that the electricity stations and motor force works, which produced a deal of smoke, should be placed among establishments which were regarded as dangerous, unhealthy, or inconvenient.

What with the smoke difficulty and the obstruction caused to the traffic by the laying down of the canalisation, the electric light is receiving quite its fair share of attention in Paris. It is also being discussed now from another point of view, one of our contemporaries printing the following article under the heading of "Precautions to Take":—

A beginning has hardly been made to instal the electric light in Paris, and already it begins to show itself as a cause of accidents. This is nothing surprising, and is not of sufficient gravity for one to deduce therefrom the condemnation of this kind of lighting. Side by side with its particular inconveniences it presents great advantages, which are

quite special to it. But in the facts which were set forth at the Municipal Council recently in connection with the fire and explosion caused by electricity in a café on the boulevards, an accident which was the twenty-first which had happened at the same place, one conclusion was seen very clearly—an effective surveillance of the electrical posts and installations. At the present moment, small electrical installations made inside a house, when the electro-motor power does not exceed 60 volts for alternating currents and 500 for continuous currents, escape every kind of surveillance. One is not even obliged, before establishing them, to previously officially notify the competent authority or the prefecture of police.

This is an instance for obtaining an alteration in the present state of things; but as time will be necessary, and that maybe the instance will not come to anything, there is certainly something else to do. Why should not the authorities of the City of Paris introduce into the agreements for concessions of electric lighting conditions of a nature to protect public safety? Why should they not require, for instance, the concessionaries to agree to an efficacious inspection of *all* their installations by a competent administrative service? Why not compel them also to establish their works and stations under such conditions that neither smoke, vibrations, nor other inconveniences of which complaint has been made should arise in the future? The electrical concessions are a bargain, an agreement between the authorities of the city and the concessionary; no one, therefore, could object to the former requiring from the latter, in exchange for advantages conceded, certain dispositions which are now recognised as necessary for the public safety and health. This is the more necessary, as the agreement between the city authorities and the Gas Company will grant the latter—if it be definitely settled—the right of working the electric lighting, and the working of the Gas Company will very probably be by means of small installations of the nature of those which at present escape all species of control. It is not therefore useless, in our opinion, on this particular point to call not only public attention, but also that of the Third Committee of the Municipal Council and that of the Council itself, to the subject. The precaution which we indicate would quite naturally find its place in the agreement which the Third Committee of the Municipal Council has under consideration at the present moment.

**THE ARTIFICIAL LIGHT OF THE  
FUTURE.\***

By PROF. EDWARD L. NICHOLS.

AS we review the history of the electric light, we find that in two respects there is little cause for congratulation. When we come to consider the quality of the light produced and the efficiency of the apparatus as a light-making machine, we find that the incandescent lamp of to-day produces the same quality of light which the earliest examples of its type were capable of giving. It is true that the efficiency of the incandescent lamp has gradually risen from 5 to 3 watts per candle, but those who have had occasion to trace the discouraging life curves of such lamps know how little real progress the change implies. We start a well manufactured lamp at any temperature we please, provided that we do not pass a certain limit, beyond which the life of the lamp would be too seriously curtailed. The initial efficiency may be made as large as we please, within that limit; but it is only a question of a few days or hours when the lamp will have dropped to the dead level of mediocrity, the 5-watt level which seems to mark the confines of permanency in the case of incandescent carbon.

\* Abstract of paper read before the New York Electric Club, November 20th, 1890.

In some experiments made by me, in the first instance a lamp was started at the candle-power indicated by the maker, and was held at constant voltage by means of the current from a storage battery. The initial candle-power was 16, which was obtained at the expenditure of 3.015 watts per candle. Measurements of electromotive force and current were made at intervals of about 10 hours, during the 800 hours that the lamp lasted. The candle-power was redetermined at intervals of about 100 hours. The voltage never rose more than 0.65 volt above its initial value, and then only for a short time. The average electromotive force of the entire run was 0.40 volt below the initial value. The characteristic features were rapid, followed by slower falling off in candle-power, the decrement amounting finally to more than 50 per cent., and rapid, followed by slower, falling of efficiency, to a final value of 5.75 watts per candle. These changes were accompanied by continuous and marked increase in the resistance of the filament.

If it be asked whether this individual case represents a state of affairs common to all incandescent lamps, I can only say that in my experience, which is certainly much less extensive than that of some others, I have known of no class of lamps the performance of which did not agree approximately with the latter results. Mr. W. H. Pierce,<sup>†</sup> who described extended tests of the initial and average efficiency of incandescent lamps in a paper read before the Institution of Electrical Engineers some time ago, recorded no exceptions to this rule of decreasing candle-power and efficiency with time.

This falling off in candle-power exhibited by lamps maintained at constant voltage can be met by a procedure not easily applicable, perhaps, in commercial work, but readily carried out where the object in view is simply to study the behaviour of the lamp under unusual conditions. The method consists in raising the electromotive force at short intervals of time by amounts sufficient to restore the candle-power to its normal value.

The results of such an experiment performed upon a lamp showed that under this treatment the life of the same was not quite 100 hours. The total rise in electromotive force during the test amounted to about 9 volts; the efficiency decreased from 3.118 watts per candle to 3.468 watts per candle. The resistance of the filament rose from 221.6 to 234.8 ohms. During the first 50 hours the changes were slight, then occurred a sudden increase of resistance, accompanied by marked rise in electromotive force and in amount of energy consumed.

The life history of the incandescent lamp at still higher temperatures does not differ essentially from that which we have just been considering, but the changes in question go on much more rapidly.

In another experiment, a lamp was started at 57 candles. It was maintained at constant voltage for 11 hours and 30 minutes, when it went out. During its brief life the candle-power fell to 24.6c., and the watts per candle increased from 1.58 to 3.09. The loss of candle-power during the experiment was 55 per cent., an amount which corresponds very closely with the loss suffered by the first lamp tested during the 800 hours that it lasted. In the case of another lamp, the initial candle-power (64 candles) was maintained throughout. Its life under these circumstances was 140 minutes, during which short period it had been found necessary to raise the electromotive force from 114.08 volts to 129.53 volts. The efficiency of the lamp fell, meantime, from an initial value of 1.33 watts to 1.677 watts at the end of the first hour; then more and more rapidly to 1.945 watts at the end of the test.

The conclusion to be reached from these data, and from the great mass of experimental results which has accumulated since the incandescent lamp has become an object of investigation, is only too evident. The efficiency of an illuminant in which carbon is the glow-

ing material is a function of the temperature. It appears that the incandescent lamp is fairly stable only at temperatures for which its efficiency does not exceed about five watts per candle. We have just seen what occurs when one attempts to maintain lamps at degrees of incandescence corresponding to a much higher temperature. It is, perhaps, not possible to point out with perfect definiteness all the causes that are at work to reduce the candle-power. The black coating which gradually forms on the interior of the lamp-bulb intercepts more and more of the light from the filament as the age of the lamp increases.

With regard to the absorbing power of this film, it was found that this was very nearly uniform throughout the spectrum, so that the blackening of the lamp had no appreciable effect upon the light which it emitted; also that the absorption at the end of 200 hours was considerably more than half as great as that at the end of 800 hours, and that the total loss of candle-power due to blackening was about 22 per cent.

These measurements enable us to account for rather more than one-third of the loss of candle-power suffered by the lamp. We are not, with our present knowledge, in a position to speak so definitely concerning the other two-thirds, but the increase in the resistance in the carbon indicates another source of diminution. That gradual failure of the vacuum which the use of the spark coil would unquestionably have enabled the observers to detect, may well be answerable for the rest. Now, the temperature of an incandescent lamp filament at 5 watts per candle is very nearly the same as that of the carbon in the light-giving flames produced by the combustion of oils and gas, and it appears that the attempt to pass this temperature introduces difficulties of such a nature as to lead to the serious question whether we have not reached a definite limit, beyond which incandescent carbon ceases to be permanent.

At that limit the efficiency of the lamp is very small indeed, 95 per cent. or more of the radiant energy emitted being of wave lengths too long to afford light.

As to the arc light, no more encouraging report can be made. On the contrary, it is perfectly well established that the quality of the light, instead of increasing, has fallen off, in the course of the development of the lamp from the clock-work regulators of Dubosc and Foucault, with their slender carbons, to the commercial lamps of to-day.

In the vast accumulation of experience which the past years have witnessed, nothing has come to general knowledge which looks to the raising of the barrier which blocks our progress. It seems only too probable that the limiting temperature at which carbon can be used for the production of light has been reached, and with it the maximum efficiency of artificial illumination.

What is to be the light of the future? From the standpoint of the engineer, I will frankly say that I cannot answer that question; but abandoning the directly practical point of view, there is something to be said. I need offer no apology here for presenting facts, the application of which is at best remote, and the present importance of which is therefore rather scientific than utilitarian; nor need I remind you that all the so-called "forces of nature" which have been yoked and impressed into the service of man, were the object of scientific curiosity, and the subject of scientific investigation long before the idea of a practical application was entertained.

The number of elements and of compounds capable of sustaining a high temperature without dissociation or change of state is very large. Carbon is the only one of these, the capabilities of which, as a source of light, can be said to have been fully tested; and yet all the others, when heated to a proper point, emit light-giving radiation. Take for example the metallic oxides. We heat the oxide of calcium in our magic lanterns, and it gives us a light of great intensity, and but little inferior to the arc light in whiteness. The exceeding clumsiness of our method of rendering it incandescent, however, has prevented its adoption, excepting for cer-

<sup>†</sup> W. H. Pierce: *Transactions of the American Institute of Electrical Engineers*, vol. vi., p. 293.

tain special purposes. We burn magnesium in fire-works and for photographic flash lights, and occasionally we indulge in the luxury of igniting a bit of the ribbon, and admiring, for an instant, the intense brilliancy of its flame. Now, magnesium is one of the most abundant elements on the face of our planet. It is a rather costly metal at present, being quoted at 50 cents an ounce in this country, and at about half that price on the continent of Europe. Even under the limited demand for it which exists at present, it has fallen to about one-tenth of its price of a few years ago, and I feel sure that it lies within the power of the electrician to greatly further reduce the cost of production. Among artificial illuminants, magnesium has in one respect no equal. W. H. Pickering, who studied its spectrum in 1880, found it to approach sunlight in quality even more closely than the electric arc light does.

Weight for weight, magnesium affords more than 30 times the light obtained from gas, with the development of much less heat. The quality of the light is such that merely from the standpoint of illuminating power, to say nothing of the additional æsthetic value of a light which approaches sunlight in whiteness, each unit of it must be regarded as the equivalent of rather more than 1.25 units of light.

The study of the radiation of the metallic oxides above the red heat reveals the existence of properties which lead us to regard them as being luminescent "by heat." It is from such bodies that radiation of high efficiency is to be looked for. We have in magnesium oxide a member of this particular class, and when it is heated in the process of formation it gives us a light the efficiency of which is unapproached by that of other artificial illuminants.

The problem is easily stated. (1) We need a body which is rendered vividly luminescent by heat. The metallic oxides would seem to offer us many such. (2) The material is to be brought to the temperature at which its luminescence is most marked. Does it not seem probable that the best method, as in the case of carbon, will not be that of direct combustion, but of heating through the agency of the electric current? (3) The material must be restored from time to time. Whether rejuvenation is to be secured through electrical, chemical, actinic or mechanical means remains to be determined.

Luminescence "by heat" offers, however, only a partial solution of the problem of the highest efficiency. However great the efficiency of the luminescent itself, it is accompanied by incandescence of the ordinary kind. The ultimate solution is to be sought for along other lines. Incandescence is too expensive a means of exciting luminescence. There are many other ways in which it may be generated; friction, chemical action, the impact of light waves, electrical excitation, certain vital processes, are known to result in the production of light. The physics of these phenomena is, for the most part, undeveloped. I know of but two attempts to determine the efficiency of this "light without heat," as it has sometimes been called. The intensity is, as a rule, very small, and the heat has doubtless been regarded as quite below the range of even our most sensitive apparatus. One of these two cases is of especial interest to the electrician. It is that of the spark discharge in vacuo. Prof. S. P. Langley and Mr. F. W. Very, in a recent remarkable paper, entitled, "The Cheapest Form of Light," speak of the heat generated in the Geissler tube as so minute as to seem to defy direct investigation. It has, however, been successfully measured by Dr. Staub, of the University of Zurich, by means of one of the most delicate instruments for the measurement of heat—the Bunsen ice calorimeter.\*

In Staub's experiments the vacuum tube was smoked with lampblack and inserted in the ice calorimeter. The ice melted in a given time afforded a measure of the total heat generated by the electric discharge through the tube. A repetition of the determination with the unsmoked tube, under which conditions the

light-giving rays could escape, gave the energy of the non-luminous radiation. The efficiency was found to be 3.268 per cent. The extremely small candle-power of light derived from the electric discharge in vacuo, may seem to preclude all questions of its utilisation in practical illumination. The result is one, however, which should not be lost sight of. It suggests a field of investigation which may prove unexpectedly fruitful.

The Geissler tube effect was not the source to which Langley and Very applied the term "the cheapest form of light." The subject of their research was the light of a Cuban firefly. Their work cannot fail to excite the highest admiration of everyone who is able to appreciate the difficulties of such an investigation. The exploration of the heat spectrum of so insignificant a source of light is a task which very few physicists would, I think, have considered practicable, but it has been carried through by these investigators with complete success.

When we study the curve of distribution of energy in the spectrum of the fire-fly thus obtained, and compare it with the corresponding curves for gas light, the arc light and sun light, we find the expression, "the cheapest form of light," which is applied to the light of the fire-fly by Langley and Very, to be fully justified. All the energy of its spectrum is massed within the narrow limits of the visible spectrum, and what is more, by far the greatest part of it is in the form of rays which are especially important for the purposes of radiation, the particular rays which give us yellow and green light. The non-luminous radiation which accompanies the light of the fire-fly seems to be so insignificant that it was with difficulty that it could be estimated, even with the almost inconceivably delicate apparatus used by Langley and Very. They give the efficiency as about 400 times as great as that of a gas flame. It cannot fall appreciably below 100 per cent.

I have endeavoured to show that the efficiency of our present methods is too low to meet the demands of the future for economical illumination, and that whether we ever succeed in approaching the perfect economy of nature's light-making processes, as exemplified in the fire-fly, or not, there are many sources of light which promise high efficiency.

## THE ELECTRIC LIGHT AND THE PARIS MUNICIPAL COUNCIL.

[FROM A CORRESPONDENT.]

IN the session of November 24th, to which we referred in our last number, a discussion took place concerning the fire which recently took place at the Grand Café. It was inquired whether the Popp Company was, or was not responsible, and whether it had, in opposition to the regulations, established electric centres in the sunk storey of the Grand Café?

The general secretary of the Prefecture of Police replied, that according to the inquiries made and the declarations received from the proprietors and the manager of the Grand Café, that the Popp Company had installed in an underground hall of the Grand Café, near the gas meter, three batteries of accumulators destined to light up the Grand Café, and partly also to supply a certain number of customers of the Popp Company. The proprietor of the Grand Café had given a written authorisation to the Popp Company to establish a small electric station in their sunk storey, in return for a reduction in the charge for lighting up the establishment; it is alleged that this station supplied about 1,400 lamps outside the café. A continuous current Gramme machine, of 350 volts, sent the current to charge the accumulators. The attention of the council was called to this figure of 350 volts, as of great importance. The engineer of the Popp Company and the manager of the café have declared that safety wires existed in the cables of distribution. As regards the supply cables, the declarations are contradictory. The manager of the café asserts that it is at least the twentieth time that fire occasioned by elec-

\* G. Staub: Inaugural Dissertation, Zurich, 1890. (See the *Beiblätter zu den Annalen der Physik*, 14, page 538.)

tricity has broken out in the café. Two conclusions may be drawn: at present, in most cases, the accidents are produced by the melting of the gutta-percha and the ignition of the wire. A similar accident took place two days later in the Rue de Montmartre and in the place de la Madeleine, the same company having the concession. However, such accidents occur with all the companies. The section of the safety wires is not made proportional to the tensions which it supports and the currents by which it is traversed. It does not fulfil its function. As soon as the current increases in intensity the wire becomes heated, the gutta-percha melts, the wire burns, and a fire breaks out.

The secretary also mentioned as a cause of danger, that small installations in the interior of one and the same property are exempt from the formality of giving notice if the E.M.F. of the generator does not exceed 60 volts for alternating currents, and 500 volts for continuous currents. Such installations like that at the Grand Café can lawfully work in secret. If the company burns down the establishment, no one is authorised to interfere. A modification of the law was therefore urgently demanded, and the universal introduction of safety wires was insisted on.

Another complaint was brought forward on behalf of inhabitants of the Rue Montmartre, who are annoyed by the smoke from an electric station fixed in a neighbouring brewery. Shopkeepers complain that the "blacks" issuing from the enormous chimney damaged their goods. The remedies suggested are the prohibition of coal in boiler furnaces, and the use of coke or of smoke-consuming arrangements.

Many difficulties, however, were pointed out; coke is expensive, and at the electric stations coal of low quality is used from motives of economy. Smoke consumers are not perfectly satisfactory.

The secretary of the Prefecture of Police reminded the council that the visible smoke is not the entire question, as there are injurious gases, such as sulphurous acid, given off in quantity which cannot be got rid of by "smoke consumption" or by the use of coke.

It appears that the electric stations within the city are more especially accused of producing smoke. It was at last resolved, on the motion of M. F. Duval, that there should be distributed to the members of the council, copies of the agreements made with the electric companies and of the agreement giving the Popp Company the right to establish underground channels in Paris.—*L'Electricien*.

## SOME FACTS CONCERNING GUTTA-PERCHA.

(Continued from page 673.)

The study of the gutta-percha trees, from a botanical point of view, the investigation of the conditions surrounding them from a scientific as well as commercial standpoint, may, M. Sérullas says, be divided into two periods. The first embraces private exploration conducted by such well-known names as Lobb, Oxley, Maingay, Teysmann, Binnendijk, Beccari, Van Leer, and Motley. The second, which may be considered to date from 1881, comprises investigations carried out by various Governments in the interests, primarily, of submarine telegraphy. These include researches effected by Seligman-Lui, on behalf of the French Government, in 1881; Wray, for the English Government, in 1883; Burck, for the Dutch Government, in 1883; and Sérullas, for the French Government, from 1884 to 1889.

During this period Morellet, a Frenchman, spent a considerable time in Malaysia studying the subject, but on a personal and commercial account; and in 1885-1886 Father Scortichini investigated the various species found in the Malay Peninsula. The notes attached to his herbarium, now at Calcutta, were intended to have

been incorporated with a history of the flora of the English Straits Settlements.

Commencing with the earlier history of the gutta-percha industry, that is to say, the first period above referred to, there appears to have been a considerable trade previous to 1842 in the hands of Chinese merchants at Singapore; and although in that year Montgomerie made the existence of the gum known to the civilised world, and specimens were brought to Europe in 1843 by Joré de Almeida, yet it was not until 1847 that Thomas Lobb discovered the tree itself, the *Isonandra*, in the interior of the island of Singapore. Ten years after this, the species was considered to have become utterly extirpated in that island, but M. Sérullas discovered a few specimens still surviving in the year 1887.

Between 1847 and 1857, Montgomerie made known that the *isonandra gutta* was to be found plentifully distributed throughout the forests of Sarawak (Borneo), and in the jungle of the Malay Peninsula. He stated that there existed in Malaysia three kinds of gutta, apparently similar as to the tree, but very different in the qualities of the gums, which were distinguished by the natives under the names of *guirek*, *taban*, and *pertcha*.

Oxley went further; he allotted to Borneo alone, seven species of gutta-percha trees. The three best supplied *gutta-taban*, and the best of three was recognised by the yellow colour of the wood.

Confusion now commenced in nomenclature. The native terms were recklessly employed, with the result that the same gum came to European markets under various designations, while absolutely different perchas were labelled with the same name.

To make confusion worse confounded, explorers in search of the *Isonandra* in Malaysian forests, returned with specimens to which purely local names had been given by the natives, the same plant bearing a different title according to the dialect of the locality; and this is not all; it is a fact that during 30 years, these explorers brought back with them not one single specimen of any value. Leaves were indiscriminately collected without regard to the age of the tree, and seldom accompanied by samples of gum obtained at the same time as the leaf.

Later on, as the forests became denuded of the better varieties, the natives made use of species such as *payena*, *bassia*, *sideroxylon*, *chrysophyllum*, and *mimusops*. Used at first secretly for adulteration, these varieties of gum were shortly openly employed in mixtures, to which, again, native names have been given, regardless as to their just application. For instance, the Malaysian name of the *payena Leerii* is *gueutta seundek*; but the *guttas-seundek*, as known to commerce, are nothing but complex mixtures.

As the above-mentioned varieties became scarce, the natives entered upon the collection of varieties such as the *soughi-soughi* of Singalang, in Sumatra (the *bassia-pallida* of Burck); the *gourhou* of Selangore, in the Peninsula, and in Borneo (the *bassia motleyana*, of Clark); the *fonou* of Tringalang and Pahang, in the Peninsula (the *ganua chrysocarpa* of Pierre); the *simpor* of Larout and Perak, and the entire south of the Peninsula (the *sidero-carpus Beccarii* of Pierre, or the *dichopsis maingayi* of Clarke).

Lastly, a fresh series of adulterations have recently been entered upon by the employment of the *djeloutong* (*dyera luziflora* of Clarke), from Malacca; the *varingin bringin* or *djerindjing* (*urostigma benjaminum*, of Miquel), from the Malay archipelago; and the *pohon Saoua* (*mimusops Kauki*), from the Celebes.

Travellers and botanists have introduced to the notice of the gutta-percha industry, as possible successors to the *isonandra*, a *chrysophyllum* from Brazil, the *mimusops balata* from Guiana, the *bassia Parkii* from Sénégal, and the *dichopsis Krantzii* from Cambodia and Cochin-China.

The French Government, in view of the rapid disappearance of the better gums, and the almost complete extinction of the *Isonandra*, and considering the critical position in which submarine telegraphy was

placed owing to no substitute for gutta-percha being known, deputed, in 1881, M. Seligman-Lui, an engineer in the telegraph service, to make a thorough and comprehensive examination into the actual conditions and circumstance attending the gutta-percha industry.

To the general confusion in nomenclature thus established, M. Seligman-Lui's report to the French Government, which we reviewed in our issue of April 12th, 1884, bore ample testimony, and, curiously enough, M. Seligman-Lui, as we then pointed out, had himself fallen into several errors in the classification of various species, due, no doubt, to the same causes which had led other investigators astray.

With the mission of M. Seligman-Lui the second period may be considered to have commenced. But, continues M. Sérullas, this expedition could not, in the circumstances, succeed in obtaining any definite or conclusive result. How, he asks, could an investigation extending over a few weeks only decide questions which so many explorers, during more than 30 years, had been unable to elucidate.

The voyage, therefore, resolved itself into a search conducted in the forests of Assahan, Sumatra, for some kind of tree which would supply a gum suitable for telegraphic purposes, and any subsequent expedition, instead of undertaking the quest of an *Isonandra* of a particular species, would merely have to apply itself to an examination of a given gum under a local name, and in a forest indicated.

One of the principal objects of M. Seligman-Lui's mission was to discover a tree giving the desired gum, which might be successfully cultivated in French territory. In the forest of Singalangan, on the river Ayer-Siloh, at the extreme limits of the Assahan district, M. Seligman-Lui noticed six kinds of trees called *mayang*, which were easily distinguished from one another. Among these one variety was found, the *mayang taban derrian*, which supplied a gum of the best quality, and which might, without any hesitation, be cultivated, in Cochin-China. Another variety, called the *gutta-batou*, gave a second-class gum, while the rest, known to the natives as *belouk djerindjing*, *korsik*, and *kalihara*, or *kartas*, produced a sap of no value. Young plants of the required species were collected and sent to the French colony at Saigon; and at Siak and Pakan Barhon plants of the *gutta seundek*, and *gutta taban* were obtained and forwarded to the same place.

The authorities in charge of the botanical gardens at Saigon unfortunately lost all these plants, and the Government of the British Straits Settlements was applied to for assistance in the matter. So urgent were the demands, that the Straits Government, convinced of the importance of the subject, deputed Mr. Wray to thoroughly investigate the gutta-percha industry in the State of Perak.

Mr. Wray was especially well qualified to undertake such a mission. Botanist and chemist, he spoke the Malay language perfectly, and in comparing the results of his expedition with those attending M. Seligman's voyage, it is only fair to the latter to mention that in addition to the advantages above indicated, Mr. Wray possessed superior facilities in the matter of time, transport, and finance, as well as exercising absolute control and authority over the natives.

Specimens of nearly every variety of gum-producing tree growing in Perak were collected by Mr. Wray. These specimens consisted of branches, flowers, fruit, wood, bark, and gum, and sufficient samples were obtained to supply the museums of Kew, Calcutta, and Taiping (of which Mr. Wray was director) with complete collections; a further set of specimens was given to Madame Errington Delacroix, who subsequently presented the collection to the Paris Museum of Natural History.

Although Mr. Wray's report was published in December, 1883, little or nothing is known of this, in every sense remarkable, expedition, either in France or Java. M. Brau de Saint-Pol Lias is credited with the discovery of the *gueutta taban mérah*, and M. Erring-

ton Delacroix is spoken of having brought to light the *gueutta taban soutra*.

Yet both these trees, which supply most excellent gutta, were discovered by Mr. Wray; the first mentioned at Oulou Plouss, the second at Oulou Kénéring.

Besides these two varieties, the following trees, whose gums are exclusively used for the purpose of falsification and adulteration, were found by Mr. Wray:—

*Gueutta Seundek* (or *Payena Leerii*; from Sapetang and the Buto River. There are two varieties in the province of Larout.

*Taban Pouteh*; from the forest of Larout, Kouala Kangsan, Hipoh. Also found in Lahat, Djouang, Tapa, Oulou Pahang, &c.

*Taban Tchaier*; from the falls of Larout, Perak, Pahang, and Patani. There are several varieties of this species.

*Simpur*; from Oulou Kénéring, Oulou Ploss, Slem, &c.

*Simpur*; another variety from the falls of Larout.

*Djeloutong*; from Larout.

*Gourbou*; from Larout.

The action taken by the Government of the English settlements in the Straits, as a result of Mr. Wray's expedition, was to forbid the cutting of any gutta-percha trees throughout British possessions. This interdiction came, however, too late, as, not long after Mr. Wray's mission, many of the forests explored by him had been entirely denuded of gutta-percha trees.

When M. Sérullas visited Malaysia he had the advantage of being accompanied on one of his trips into the forests by Mr. Wray, who appears to have placed his notes and reports at the disposal of the author of the present article.

(To be continued.)

## MR. GLADSTONE AND THE TELEGRAPH SERVICE.

THE Right Honourable William Ewart Gladstone has, during his eventful and phenomenal career, been compared favourably and unfavourably to classic mortals and immortals of all types and shades, from "the wily and familiar conjuror," and the indefatigable hairsplitter of everything argumentative, to the simple "Grand Old Man," and the modern embodiment of much anciently held sacred by Greece and Rome. Hero worship, indeed, has caused him to be looked upon by many as the Alpha and Omega of nineteenth century progress, and no praise has been deemed too extravagant wherewith to belaud the vigorous and hearty octogenarian statesman. Those who have not indulged in such perfervid pæans, but have gone to the other extreme, and heaped abuse and unstinted obloquy on the name and fame of the "people's William," stand very much in the position of the negative to the positive current—the zinc to the copper, technically speaking—and the one seems to be, in a sense, indispensable to the other.

It is not our intention to indulge in a political disquisition in these matters, but it may be interesting to our readers to know that in the telegraph service generally, Mr. Gladstone is regarded as a sort of political and telegraphic Hannibal, one whose movements and speeches are regarded by telegraphic clerks with peculiar interest, not to say anxiety, for there never has been a statesman, nor indeed any public man, whose utterances have been so assiduously snapped up by journalists, and incontinently hurled, through the medium of the telegraph service and the press, at the heads and hearts of an always inquisitive reading public.

Into the political aspect of the position of the parliamentary Hannibal we need scarcely enter at great length.

The mighty Carthaginian, the terror of Rome, after crossing the bleak and tempest-scourged Alps, and descending into the fertile valleys of the Po in making his final arrangements for the wonderful campaigns which enabled him to maintain himself in aggressive

hostility to Rome for fifteen years, destroyed the whole of his transport and supplies—a bold and daring step—but fortune favoured him, and his victorious troops found supplies and spoil in plenty in the camps of their routed adversaries.

The modern political Hannibal, it is said, has abandoned his line of communication and his allies, and even now looks with contempt upon those who, in the past, helped him to build up the fame which will make his name a landmark in English history.

The allies of the modern political Hannibal, however well meaning his intentions may be, are not to be mentioned in the same breath with those faithful warriors who followed the amiable and generous-hearted son of Hamilcar through his many vicissitudes in Italy. Unlike the Carthaginian's experience, victory has not at the outset declared itself for the Old Parliamentary Hand, and there is apparently very little or no prospect of it in the near future for those who follow his fortunes.

Returning now to the telegraphic Hannibal, it may be said that were the extra labour and skill called into play in the telegraph service on the occasion of a Gladstone "night" unrewarded, in a pecuniary sense, the alarm and consternation with which the news of the advent of Hannibal into Italy was received in Rome would find a strong professional chord in the heart of the apprehensive telegraph clerk. The first and greatest Midlothian campaign—that of 1880—produced great receptions, great orations, and great political results. An army, so to speak, of reporters plunged into the sea of words, sentences and periods were seized as they flowed in exuberant profusion from the unwearying lips of the great and popular favourite of the million. From the journalist to the telegraph clerk is but a family transfer. In Edinboro', a small army of telegraph clerks, or, as they are now termed, telegraphists, was engaged unremittingly in preparing and sweeping over the wires, north, south, east, and west, the sympathetic sentences of the Old Man militant. Thousands upon thousands of words were dealt with expeditiously and methodically each evening, providing close and monotonous work for hundreds upon hundreds of men throughout the whole English telegraph system. Abundant in rhetorical resource, as the Hannibal of old was inexhaustible in military intuitiveness, Mr. Gladstone is equally at home on the divine blessings of peace, the glories of national freedom, Home Rule, Crown Derby, Homer, large potatoes, the use of jam, or the study of Moses, it follows that the telegraph clerk plays no mean part in the presentation of his utterances to the public. After the Midlothian campaign came the introduction of the Home Rule Bill by Mr. Gladstone in 1886. The scene in the Central Telegraph Department was one never to be forgotten. The day was dull and dark, auguring no good for the gigantic task which the veteran Prime Minister had undertaken in the House of Commons. He began at about half-past four o'clock, and spoke for nearly three hours.

From 4 o'clock in the afternoon until 3 the next morning, upwards of 400 men were engaged in dealing with the transmission of press work incidental to the propounding of this short-lived scheme alone. Extraordinary preparations of circuits, extension and making up of wires, insertions of relays, repeaters, testing of batteries, &c., had been engaging the attention of the officials for some days previously. The heads of departments honoured the scene with a visit, and they must have been surprised to find that the noise alone made the work seem like that of a factory. The number of words telegraphed aggregated fully one and a-half millions. The spirit of the moment was fully entered into by the staff, and the scene was animated beyond all description. Men were seen hurrying here and there with work for the hundreds of operators to whom the task of preparing slips for the Wheatstone automatic had been allotted. Others were to be seen deciphering the wretched "copy," which is generally the source of numerous errors, and also of loss of time. Everything is done on these occasions of extraordinary pressure in a methodical and systematic manner, every

man falls into his place, and knows what is required of him to help the general exodus of business.

Through all these times of important pressure, the sheet anchor of the service, and the only one by which monster speeches can be satisfactorily dealt with, is Sir Charles Wheatstone's automatic system of telegraphy, improved very much certainly since its introduction by the inventor upwards of 20 years ago, but still in principle very much the same beautiful, reliable, and perfect medium of communication.

It is a common practice in the General Post Office for the Postmaster-General to express his thanks to the staff for their extremely hard and trying labours at Christmastide, Eastertide, and on occasions of great strain on the service. There are, unfortunately, very few instances where similar compliments have been vouchsafed to those performing such trying and harassing work as telegraphy in times of strain and pressure, and such instances not infrequently occur. Every gale or disturbance of the elements leaves its mark on the material of the service, and the hackneyed remark is often passed round that, notwithstanding the general improvements effected in the maintenance of wires, batteries and circuits, Nature now and again reminds us that telegraphy, like some of the other sciences, in a measure is still "at the mercy of the elements." Many a disappointment is experienced by the telegraph clerk when these great speeches or great demonstrations occur; he has on such occasions to give up his science class, his art class, his music, his literature, his friends, and the pursuit of pleasure, and it may be of knowledge also. "Duty" is as serious a matter to him as it is to the sentry on his lonely guard. However, he bears it cheerfully and steadfastly, feeling a genuine interest in his duties, and expecting no higher reward than to hear that all went well on the occasion of the great speech, banquet, or demonstration.

Mr. Gladstone has had greater attention paid to him in the matter of his speeches than any other public man during the past 25 years, but this does not mean that other statesmen and men of fame and position at home and abroad are by any means neglected. It simply shows that Mr. Gladstone in office or out of it, popular or unpopular, is read, and we may add criticised, by the masses of his fellow countrymen to a greater extent than is the case with his colleagues past or present—Liberal or Conservative. The recent Midlothian speeches also entailed much expensive labour to the telegraph service, for it is notorious that press work, owing to the absurdly low rate at which it is charged, is a source of great loss to the Department, and on this point we may have something to say hereafter.

## INDUCTION AND INDUCTION COILS.

By W. MOON.

THE phenomena exhibited by the variation of the number of lines of induction through the core of an ordinary induction coil may be divided into two parts. Firstly, when the discharge is non-oscillatory, and, secondly, when it is oscillatory. It is with the former of these divisions only that I deal with in this paper.

If  $l$ , lines of induction, are threaded through the core of a coil of  $n$  turns, joined up to a circuit of resistance  $R$ , then the quantity  $q$  of electricity produced in the circuit will be

$$q = \frac{n l}{R} \quad (1)$$

Also, if an E.M.F., capable of producing a steady current  $C$ , is put in a circuit, then each time the current is started a quantity of electricity

$$q = L \frac{C}{R} \quad (2)$$

will be kept back that would have been generated but for the existence of the coefficient  $L$ .

Owing to this factor  $L$  impeding the starting of the current in the circuit in a similar manner to that in which the inertia of a body opposes the force setting it in motion, it has been aptly called the electro-magnetic inertia of the circuit. But the shorter but less expressive term of inductance is now more generally used.

The quantity  $q$  in (1) is quite unaffected by the presence of any other circuits upon the same electro-magnet. For if  $l_1$  of the same lines of induction are threaded through another coil of  $n_1$  turns, then the quantity

$$q_1 = \frac{l_1 n_1}{R_1} \quad (3)$$

will be induced in this second circuit while  $q$  remains unaltered.

Also when the current,  $c$ , is started in the primary circuit the quantity

$$q_1 = m \frac{c}{R_1} \quad (4)$$

will be induced in the secondary circuit, while the value  $q$  in (2) will also remain unaltered.

From (1) and (2) we get

$$l = c \frac{L}{n}. \quad (5)$$

And, thus, the number of lines of induction threaded through a coil can be determined when the inductance and number of turns upon the coil are known.

Also from (3) and (4)

$$l_1 = c \frac{m}{n_1} \quad (6)$$

And from (5) and (6) we get

$$\frac{l_1}{l} = \frac{m}{L} \frac{n}{n_1}. \quad (7)$$

A formula by which can be determined the fraction of the whole number of lines of induction generated by the primary circuit that are usefully threaded through the secondary circuit.

If  $l$  equidistant lines of induction cross an area  $a$  then the tension along those lines of induction, that is, the pull across the area  $a$

$$= \frac{l^2}{8 \pi a} = \frac{c^2}{8 \pi a} \frac{L^2}{n^2}. \quad (8)$$

The energy absorbed from the primary circuit in generating the lines of magnetic induction through the core of a simple electro-magnet  $= \frac{E q}{2}$  where  $E$  is the E.M.F. of the battery.

From (1) and (2)

$$\frac{E q}{2} = \frac{c n l}{2} = \frac{L c^2}{2} \quad (9)$$

To get as great a pull with as little expenditure of energy as possible in creating the lines of magnetic induction, we must make the quotient of (8) and (9) a maximum

$$\frac{l}{4 \pi a c n} = \frac{L}{4 \pi a n^2} \quad (10)$$

This last expression is useful in the construction of rapidly responding apparatus such as telegraph relays. But in other apparatus it is necessary to get as great a pull with as small a rate of expenditure of heat in the coils as possible; in that case

$$\frac{L^2}{8 \pi a n^2 r}$$

must be made a maximum, where  $r$  is the resistance of the coils of the electro-magnet.

The energy expended by a battery of E.M.F.,  $E$ , during a time,  $t$ , sufficiently long to admit the current arriving at its permanent state

$$= E (c t - q) \quad (11)$$

where  $q$  is the quantity of electricity damped back by  $L$  on starting the current.

Filling the value of  $q$  in (2), in (11) the energy expended by the battery becomes

$$\frac{E^2}{R} \left( t - \frac{L}{R} \right) \quad (12)$$

But since from (9) the part of this energy absorbed from the primary circuit in creating the magnetic field

$$= \frac{E^2}{R} \frac{L}{2 R}$$

It follows that the difference between the values (12) and (9) gives the amount expended in heat

$$= \frac{E^2}{R} \left( t - \frac{3 L}{2 R} \right) \quad (13)$$

If there is no secondary circuit this heat will be expended by the current in the primary circuit. But if a secondary circuit exists part of this heat will be expended in that circuit also.

If the same lines of induction are discharged through several secondary coils then the energy embodied in the lines of induction will be divided between the several coils in proportion to the number of turns of each, and inversely proportional to their resistances. Thus the energy expended in the coil of  $n_1$  turns and resistance  $R_1$  would be

$$\frac{E^2}{R^2} \frac{L}{2} \left( \frac{\frac{n_1}{R_1}}{\frac{n_1}{R_1} + \frac{n}{R}} \right)$$

Obviously it is immaterial whether the coil of  $n$  turns is a secondary or a primary circuit, and since  $\frac{E^2}{R^2} \frac{L}{2}$  is the energy embodied in the lines of induction threaded through the two coils, the sum of these last two values, or

$$\frac{E^2}{R^2} \frac{L}{2} \left( \frac{2 \frac{n_1}{R_1} + \frac{n}{R}}{\frac{n_1}{R_1} + \frac{n}{R}} \right)$$

will represent the energy absorbed from the primary circuit on starting the current.

Thus it will be seen that the whole energy taken from the primary circuit on starting the current cannot be twice as great as when there is no secondary circuit, but approaches more closely to that value as  $\frac{n_1}{R_1}$  becomes

great as compared with  $\frac{n}{R}$ .

The time of discharge is important in induction phenomena, as it is by the variation of this factor that the laws of conservation of energy are maintained. Let  $t$  be a time of sufficient duration to include nearly the whole of the discharge. And  $e$  and  $e_1$  the mean E.M.F. in the primary and secondary circuits during this time, then

$$e = \frac{n l}{t} = \frac{L c}{t} \quad (14)$$

$$e_1 = \frac{n_1 l_1}{t} = \frac{m c}{t} \quad (15)$$

And the energy given off in the discharge of the secondary circuit

$$\begin{aligned} &= e_1 q_1 = \frac{n_1^2 l_1^2}{t R_1} \\ &= \frac{m^2 c^2}{t R_1} = \frac{E^2}{R^2} \frac{m^2}{t R_1} \end{aligned} \quad (16)$$

By adding this last quantity to the energy expended in creating the magnetic field and to that expended in heat in the primary circuit, and equating the result to the energy expended by the battery, the value of  $t$  can be determined.

For purposes of illustration, the use of differentials may be avoided by taking proportionality only. Thus :

$$\frac{E(E-e)t}{R} \propto \frac{(E-e)^2}{R} t + \frac{E^2}{R^2} \frac{m^2}{t R_1} + \frac{E^2}{R^2} \frac{L}{2}$$

Filling in the value of  $e = \frac{Lc}{t} = \frac{E}{R} \frac{L}{t}$  we get

$$t - \frac{L}{R} \propto \frac{\left(t - \frac{L}{R}\right)^2}{t} + \frac{m^2}{t R R_1} + \frac{L}{2 R}$$

$$\therefore t \propto \frac{2}{L} \left( \frac{L^2}{R} + \frac{m^2}{R_1} \right)$$

It can be shown by Helmholtz's well-known exponential equation that this value of  $t$  is equal to the time occupied by .865, or nearly  $\frac{9}{10}$ ths of the discharge. So that we may say

$$t = \frac{2}{L} \left( \frac{L^2}{R} + \frac{m^2}{R_1} \right) \quad (17)$$

If there is no secondary circuit or if  $R_1$  is infinite

$$t = 2 \frac{L}{R} \quad (18)$$

Also if the discharge takes place in the secondary circuit when the primary circuit is broken.

$$t = 2 \frac{m^2}{L R_1} \quad (19)$$

There is an important difference between the discharge of a condenser and that of a simple electro-magnet.

The current produced by the discharge of a condenser for similar phases of the discharge is inversely proportional to the resistance, and the time of discharge varies directly as the resistance.

But in the case of the discharge of the coil the current for similar phases of the discharge is independent of the resistance while the time of discharge varies inversely as the resistance.

So that in the former case the product of the time of discharge and the current, that is, the quantity  $q$  is constant, while in the latter case, the product of the resistance and the time of discharge is constant, and the quantity of the discharge varies inversely as the resistance.

Again, in the case of the condenser, the E.M.F. at similar phases of the discharge is constant, while in the case of the coil it is proportional directly to the resistance and inversely proportional to the time of discharge.

But while the initial current and current for similar phases of the discharge are constant when there is but one circuit surrounding the same lines of induction, yet this is not the case when there are several such circuits. This evidently follows, since the quantity of electricity of the discharge from each circuit is not influenced by the presence of other circuits, while the time occupied by the discharge is affected as shown in formulas (17), (18), (19).

Thus, the initial current and current for similar phases produced in the secondary circuit on closing the primary would be but

$$\frac{\frac{m^2}{R_1}}{\frac{L^2}{R} + \frac{m^2}{R_1}}$$

of that produced in the secondary when the primary circuit was broken.

In the same manner, the initial value of the imaginary inverse current, or to speak more correctly, that of the opposing E.M.F. in the primary circuit, would be

$$\frac{\frac{L^2}{R}}{\frac{L^2}{R} + \frac{m^2}{R_1}}$$

of what it would be if no secondary circuit existed.

Hence the presence of a secondary circuit has the effect of making the opposing E.M.F. in the primary circuit smaller in amount for similar phases of the discharge. But the discharge occupies a proportionately longer time so as to maintain the quantity  $q$  of the discharge constant.

Since the value of the current in the primary circuit, where no secondary circuit exists, starts at 0, and rises to  $c$ . Therefore the imaginary inverse current must start at  $c$  and fall to 0.

Similarly if the discharge takes place through the secondary circuit when the primary circuit is broken, the values of the initial current will be

$$c \frac{n_1 l_1}{n l} = c \frac{m}{L}$$

Hence the initial value of the secondary current on closing the primary circuit will be

$$c \frac{m}{L} \left( \frac{\frac{m^2}{R_1} + \frac{L^2}{R}}{\frac{m^2}{R_1} + \frac{L^2}{R}} \right)$$

And the initial value of the opposing E.M.F. in the primary circuit on starting the current will be

$$E \left( \frac{\frac{L^2}{R}}{\frac{L^2}{R} + \frac{m^2}{R_1}} \right)$$

This phenomena presented by the ordinary spark coil depends upon this law of the time of charge and discharge of the coil being proportional to the conductivity of the circuit surrounding it.

For when the primary circuit of the coil is closed, owing to the primary resistance being very small, the time of charging the coil is great, and the E.M.F. induced in the secondary coil not sufficiently great to produce a spark. But when the primary circuit is broken there exists an electro-magnet surrounded by a secondary coil of many turns, but of very great resistance owing to the air space between the discharging points; therefore, the lines of induction collapse very rapidly and charge the poles of the secondary coil to a very high potential. And when the static charge upon the poles of the secondary coil reaches a sufficiently high potential, a discharge takes place and the energy embodied in the lines of induction through the core disappears in the spark so produced.

At any instant of time the ratio of the E.M.F. induced in the secondary to that induced in the primary coil will be

$$\frac{n_1 l_1}{n l} = \frac{m}{L}$$

The length of spark produced in the secondary circuit will, however, not depend directly upon the E.M.F. induced in the secondary coil, but upon the static potential at the discharge points, which will be somewhat less than the induced E.M.F. owing to the static capacity of the ends of the coil and the discharge points.

It is a familiar induction coil experiment to join a condenser to the two poles of the secondary coil, and thus, by reducing the static potential of the discharge points to obtain shorter sparks, but of greater volume, in proportion to the capacity of the added condenser.

The function of the condenser attached to the primary coil of all induction coils, is also, of course, to reduce the static potential at the contact points, and thus prevent sparking.

In some shocking coils, the severity of the shock is regulated by thrusting a copper or brass tube over the iron core. The function of this tube is twofold, as besides absorbing a portion of the energy given off by the primary circuit, it also reduces the rate at which the lines of induction through the core collapse, and thus reduces the induced E.M.F. in the secondary circuit.

## SMITHFIELD CLUB SHOW.

AT this show, held during the current week, the leading makers displayed some excellent specimens of steam engines, specially designed to combine the requisites of a good prime motor for electric lighting. At the stand of *Messrs. Marshall, Sons & Co.* is exhibited a 10 H.P. nominal compound stationary steam engine, erected underneath a locomotive multitubular boiler. The equipment includes Hartnell's patent automatic expansion gear, automatic sight feed lubricator, and a steam trap for draining the cylinder jackets. The engine and boiler are constructed of ample strength for a working pressure of 140 lbs. to the square inch, and are specially adapted for electric lighting. They also showed two engines worthy of special attention, one of which is a new pattern (Class "M") independent vertical engine, cylinder  $6\frac{1}{2}$  inches by 10 inches, fitted with *Moore's* patent crankshaft governor, and automatic cut-off balanced slide valve, and a patent automatic sight feed lubricator, &c. The engine is specially adapted for electric lighting, there being ample provision for lubrication, and the governor controlling the engine to such a nicety, that there is practically no variation in the speed, however much the load may change. The other is a self-contained engine of the horizontal type (Class "M"), with cylinder 10 inches by 14 inches. The equipment of this engine is exactly similar to the vertical named above, with the addition of forcepump. This is also specially adapted for electric lighting or other machinery requiring steady running.

*Messrs. Robey & Co.* exhibited a compound "Robey" engine and locomotive boiler combined, of the type so largely used for electric light installations, and for driving other machinery where perfectly steady running is required. It is very powerful for the space occupied, works with perfect regularity with very varying loads, and is extremely economical in fuel, consuming under 2 lbs. of best Welsh coal per indicated horse power per hour. The working parts are perfectly balanced, so as to run safely at high speed, and as they have large wearing surfaces of ample size they run cool under heavy loads. It is well lubricated for long runs. At this stand is also shown a high speed vertical engine, specially designed for working electric light machines on board ship, and in flour mills, but it is equally suitable for any other purpose where great power is required in small space. It is designed to work with a high steam pressure, and may be arranged to run at various speeds as may be most suitable for the work it has to do. All the wearing parts have very large surfaces, and it is fitted up with means for self-lubrication, so that it may run continuously, without any risk of heated bearings. While every part of it is thoroughly well lubricated, it is so arranged that no oil is wasted. When used for electric lighting it is mounted on a cast iron bed plate, the other end of which carries the dynamo. The baseplate is provided with lugs and adjusting screws, so that the driving bolt can be tightened without stopping the machinery. The engine is perfectly balanced, so as to run at a high speed, without excessive wear, and the whole forms a strong, durable, and compact motor, which can be thoroughly relied upon to work economically and safely during long runs, without giving trouble. Another class of engine represented is the "long stroke horizontal fixed engine," fitted with patent automatic expansion gear. This engine is designed for high pressure of 80 lbs. to 100 lbs., and is provided with steam-jacketed cylinder, with liner made of specially hard close-grained metal, extra long crank-shaft, with long bearings, solid end connecting rod, and all working parts of ample size and strength to work continuously with pressure of from 80 to 100 lbs. steam. It is fitted with Richardson's patent automatic gear and governor, which gives a range of admission from zero to three-quarters of the stroke, and a very perfect distribution of steam. A "horizontal fixed engine" was also shown, fitted with patent trip expansion gear (Class "E"). When steam engines are of large size, and work with steam of high pressure, the

working of the slide valves becomes an appreciable part of the load upon the engine, and to obviate this various kinds of equilibrium valve gear have been introduced, the best known among them being the Corliss, with rotating valves, and the Sulzer, with Cornish double beat valves, a variety of which is known as the Proell gear. All these gears are manufactured by Robey and Company, and can be fitted to their engines when required; but their large experience with the different varieties has enabled them to discern the weak points in each kind, and as a result they have produced a patent trip expansion gear, which is the simplest, most effective, and most easily worked, and gives the most satisfactory results of any hitherto made.

*Messrs. Hornsby and Sons* showed one of their under type stationary compound engines of 10 H.P., fitted with loco. type boiler, which are in use largely both at home and abroad for electric lighting owing to their economy in consumption of fuel, steadiness of running, and the small amount of space occupied. This engine is fitted with Hornsby's patent automatic expansion gear, and also feed-water heater. A vertical engine for high speed is also worthy of notice. This is of 4 nominal H.P., and is specially designed for electric lighting purposes on board ship and other places. This engine, when driving a suitable dynamo, is capable of running 80 to 100 16-C.P. incandescent lamps, and is of course also suitable for any purpose where a high speed and great power in small space are required.

Amongst the engines shown by *Messrs. Ransomes, Sims and Jefferies*, and by *Messrs. Ruston, Proctor and Co.*, there were also several particularly adapted for driving electrical machinery, of some of which we have published full particulars on other occasions.

*Messrs. Wilcox & Co.* made a good display, as usual, of machine belting, lubricators, oils, and the large variety of engine-room requisites supplied by the firm.

---

## NOTES ON ECONOMY IN CONDUCTORS IN SYSTEMS OF DISTRIBUTION OF ELECTRICAL ENERGY.\*

---

IN considering what economies it is possible to introduce into a system of conductors laid down for the distribution of electrical energy, one has at the outset to consider the relative merits of the different systems which have been proposed before investigating the best proportions to be given to different parts of the system fixed upon, and the proper current densities to be employed in them.

With regard to this first question, I do not propose to say more than a very few words, or to deal with it in any but the most general way.

It is important to observe, in the first place, that the pressure to be used in houses for lighting by incandescence lamps has been practically limited to a maximum of 100 to 120 volts by the makers of the lamps, and that the pressure in buildings may not in any case exceed the 300 volts fixed by the Board of Trade. This consideration, while greatly hampering the system of simple parallel distribution, does not affect to any great extent the rival systems employing accumulators or secondary generators.

In his Cantor lectures before the Society of Arts in 1885, Prof. George Forbes gave a very interesting account of various systems and their sub-divisions; and he showed that, except for a very limited area of compact form requiring a large amount of light per unit of area, this system of simple parallel distribution is impracticable on account of the enormous expense of mains to carry the large currents necessitated by the use of so low a voltage. For a very small and compact area such as a block of buildings, it may be worth while to consider the applicability of this system, however, on account of its simplicity and the cheapness of the class of cable that may be employed.

No practical use of the series system for general station work has been made that I am aware of, though, of course, it is largely in use for outdoor lighting and transmission of power. It has the obvious advantage of requiring comparatively small conductors, but against that must be put the expenditure necessary for providing a complete system of automatic cut-outs for every lamp, motor, or other apparatus employed, and the difficulty of regulating with any reasonable degree of economy for the varying numbers of lamps alight on different circuits. The comparatively

---

\* Paper read before the Old Students' Association, December 4th, by Hamilton Kilgour, member.

low efficiency of glow lamps for series lighting is also an important reason against the adoption of such a system.

The next system to which attention may be drawn is the series-parallel system, of which the modifications known as the three-wire, four-wire, and similar systems are the most important. These are in general use both in England and abroad, and give for certain distributions of lamps a very good result indeed.

The degree of economy to be obtained with a three, four, or  $n$  wire system over the simple parallel system depends on the certainty or otherwise with which you can rely on a continued balance of load between the different sections. This you would secure as far as possible by putting as many of each class of consumers in each section, and also, if practicable, by insisting upon the wiring of all buildings supplied being upon the same system as that of the mains, and the total load in every case distributed between the sections.

If you are sure that the load in any one section will never exceed that of any of the others by more than  $m$  per cent. of the full load of a section, and the system is one of  $n$  wires; then if  $E$  stands for the percentage reduction in amount of copper used from that necessary in an equivalent simple parallel system,

$$E = 100 \left\{ 1 - \frac{200 + m(n-2)}{200(n-1)} \right\}$$

For example, let  $m = 25$  and  $n = 3$

then  $E = 43.8$ .

If, as in a case in which all the wiring is done upon the same system as that of the mains, we may take  $m = 10$ ; and supposing  $n = 4$ , then

$$E = 63.3.$$

If in the same case we take  $n = 5$ ,

$$E = 71.3.$$

In considering these systems it is necessary, in any practical case, to take into account the increased cost of labour in putting them down, and of the conduits or pipes in which they are enclosed. In connection with this, it is worthy of remark that with underground systems of mains—such as are likely to be in vogue in future—the cost of the actual cables may amount to less than 50 per cent. of the total cost of the cables laid.

With regard to systems employing accumulators or secondary generators, there is at once a great gain in the allowance of very much high pressures in the mains. The cable is, however, very much more expensive, and the cost of the accumulators and their constant inefficiency must be taken into account in the one case, and in the other the cost of the converters and their inefficiency on light loads. In the case of accumulators it is necessary to distribute the energy from sub-stations upon some one of the low tension systems, so that there is only a partial gain in respect to copper; and with converters, and especially those for alternating currents, it is well known that their cost per kilowatt output diminishes to a considerable extent as their size increases, so that with these also it may be and is advisable sometimes to employ sub-stations, so that the same remark will apply here.

I have now very briefly alluded to some of the conditions affecting the relative economies of the chief systems of distribution of electrical energy; and I have purposely refrained from examination of them in detail for the reason that every particular case will differ to some extent from any other, and in making a choice of the system to be employed to best meet its requirements, a special investigation should be made having regard to all the conditions involved.

Before taking up any problems, such as those referred to in the abstract sent out to members, a word must be said as to the relation of price to size of cable. Bare wires, as you all know, are sold at so much a pound in general; stranded cables being a little more expensive than single wires, and wires smaller than No. 20 or 22 a little dearer than those above this size. Speaking generally, however, cables of bare wire of approximately the same cross-sectional area are sold at the same price per pound. Small insulated wires of a definite thickness of insulation, such as one of two layers of cotton or silk, are also often sold at so much a pound, but with these we have nothing at present to do, unless it be to remark that with such wires the insulation resistance necessarily decreases as the wire increases in size.

Insulated cables for use in any of the cases we have to consider are, I believe, invariably sold by length.

For a given class of insulation, and a given insulation resistance per mile, you would expect—seeing that for a given insulation the mass of the insulator is directly proportional to the mass of the copper insulated—that the prices should be very nearly proportional to the cross-sectional areas of the copper conductors. In practice this is very nearly so, for the price of a cable may be expressed by the equation

$$P = a + bA,$$

where  $P$  = cost per mile in pounds

$A$  = area of conductor in  $\frac{1}{1000}$ ths of one square inch and where  $a$  and  $b$  are constants depending upon the class of insulation and the number of strands in the cable, with considerable accuracy with the cables of some of the best known makers.

Taking Silvertown cables for example:

Class L.

7 strands  $P = 10.3 + 3.58 A$  within 2.6 per cent.

19 „ „  $P = 15.7 + 3.39 A$  „ 3.5 „

37 „ „  $P = 22.5 + 3.32 A$  „ 0.7 „

Class D.

7 strands  $P = 4.72 + 1.32 A$  „ 2.9 „  
19 „ „  $P = 7.22 + 1.27 A$  „ 4.6 „  
37 „ „  $P = 12.2 + 1.25 A$  „ 0.4 „

The percentage errors given above are the maxima, and the average are from  $\frac{1}{4}$  to  $\frac{1}{2}$  these.

In a similar way the values of the constants for the other classes manufactured by the Silvertown Company may be tabulated, but I have not thought it necessary to do so here, more especially as I have not their most recent price sheet by me.

With Fowler-Waring cables (lead covered) you would not expect this law to hold with the same degree of accuracy, as the thickness of lead is not proportional to the diameter of the cable. We have, however, for seven-stranded cables  $P = 25.9 + 2.49 A$ , with a maximum error of  $12\frac{1}{2}$  per cent. and an average error of 4.8 per cent.

The cables of Messrs. Siemens are not manufactured upon the plan of having a given insulation resistance per mile for a given class of cable; the insulation resistance of their cables of a given class diminishes as the size of the cable increases. For example, for their classes L, M, and N, the insulation resistance per mile varies from 2,500 megohms for the smallest sizes to 300 megohms for the largest. You would not, then, expect to find the price of a cable proportional to its size, nor, in fact, is it actually nearly so.

With all cables, however, which are very nearly of the same size the price is, of course, very nearly proportional to the cross-sectional area of the copper, and over a narrow range the rule  $P = a + bA$  still holds, the constants in any case being very easily determined by plotting a few points in the neighbourhood of the size you want, and drawing the tangent to the curve (or the chord through points on either side of the size you estimate is about what you require), when the ordinate of the point of intersection of this tangent or chord with the axis of  $y$  gives  $a$ , and  $b$  is the trigonometrical tangent of the angle made by the line as drawn with the axis of  $x$ , it being supposed that prices are plotted as ordinates.

Now, in any case of central station work you can estimate from experience what is approximately the cross-sectional area of copper you want, so that we may take it that, for our purposes, the rule  $P = a + bA$  holds universally. This may be regarded in the light that you pay a sum  $a$  for the privilege of being allowed to buy the cable you require from the makers you are dealing with, and for the rest the price of this cable is directly proportional to its size.

The most economical current density to employ for a constant and uniform current circuit working for a given number of hours per annum.

Let  $a$  = current in amperes;  
 $n$  = number of hours of working per annum;  
 $\rho$  = resistance of conductor of one square inch sectional area in ohms per mile;  
 $c$  = value of the Board of Trade unit in pence;  
 $d$  = sum of the rates of interest, depreciation, and repairs on capital laid out in cable;  
 $x$  = sectional area of conductor required in  $\frac{1}{1000}$ ths of one square inch;  
 $D$  = most economical current density to employ in amperes per square inch;  
 $P = a + bx$  as before;

$$\text{then } x = a \sqrt{\frac{nc\rho}{2.4bd}}$$

$$\text{and } D = 1,000 \sqrt{\frac{2.4bd}{nc\rho}}$$

For copper conductors  $\rho = 0.0425$ , hence

$$x = 0.133 a \sqrt{\frac{nc}{bd}}$$

$$\text{and } D = 7,513 \sqrt{\frac{bd}{nc}}$$

For example, if we take Silvertown class L cable, and

$$c = 5$$

$$d = 13$$

we shall have the most economical current densities for different numbers of hours per annum given by the following table:

$n$	D.		
	7 strands.	19 strands.	37 strands.
400	1,119	1,089	1,077
600	913	889	880
800	791	770	762
1,000	708	689	681
1,500	578	562	556
2,000	500	487	482
3,000	408	398	393

In this table  $\rho$  has been taken as 0.0446, which is rather higher than it should be.

No account of the increased resistance of the conductor due to heating has been taken account of in the foregoing; but as the current density to employ in a given case is known approximately from previous experience after a little, an allowance can easily be made for the probable heating in the value of  $\rho$  you decide to use.

(To be continued.)

It is a very striking example of the recuperative action of a secondary cell that you can completely discharge it, as you think, and then even charge it in the wrong direction, but it will, on being insulated, rapidly recover an E.M.F. in the original direction. Indeed, we were told of a curious case some time back. After the removal of the laboratory employed for testing ammeters from one part of a well-known London factory to another, it was found that the E.P.S. accumulators always ran

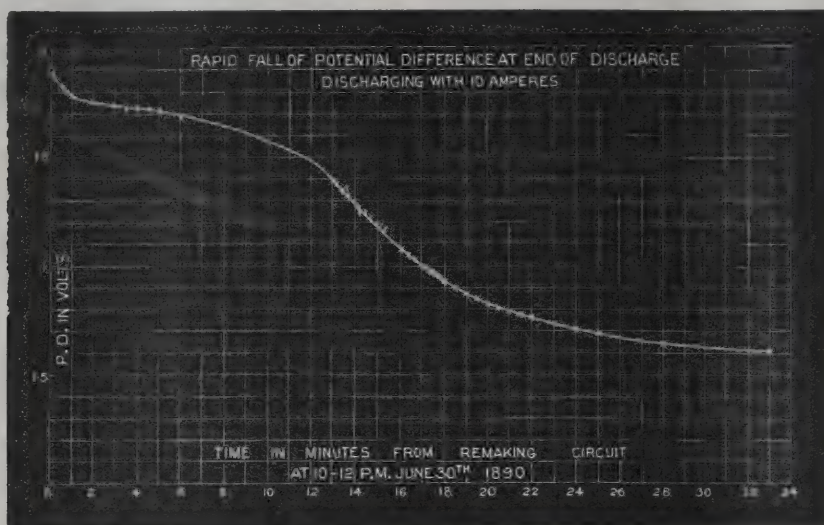

FIG. 10.

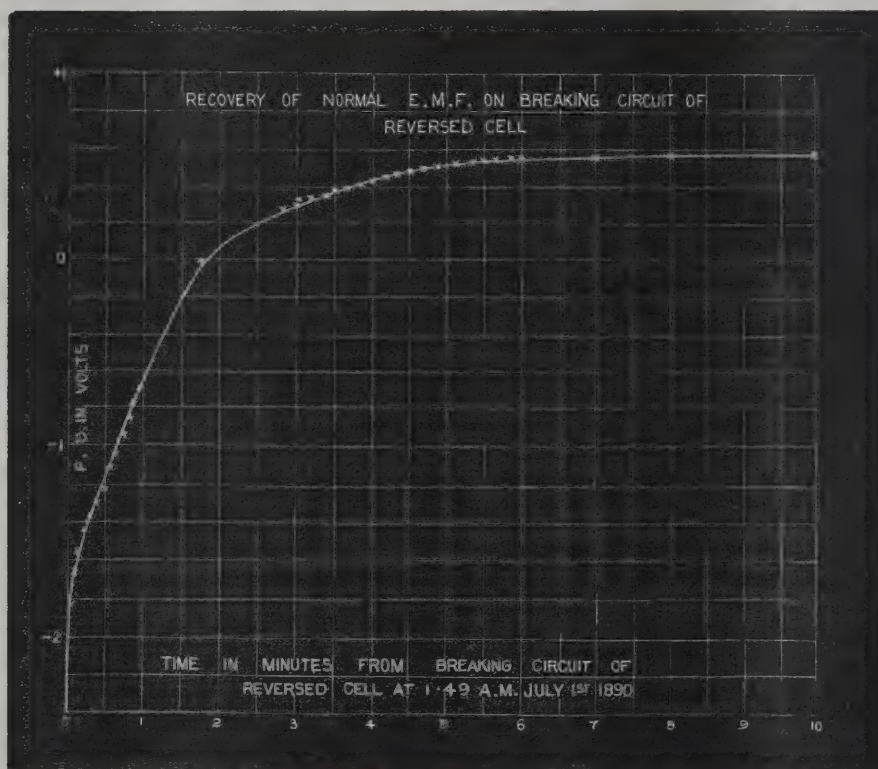

FIG. 11.

## PROCEEDINGS OF SOCIETIES.

### The Institution of Electrical Engineers.

(Continued from page 653.)

As already explained, the constant discharge current of 10 ampères was, by the employment of some auxiliary cells, kept flowing through the accumulator under test even when its E.M.F. became very small. Towards the end of the discharge the fall of P.D. at the terminals of the cell under test became extremely rapid, so that, for example, on closing the circuit after the removal of the plugs at  $\nu'$  (fig. 2), the P.D. fell from 1.9 to 0.6 volts in 33 minutes, as seen from fig. 10. This rapid fall is probably due to lead peroxide being formed on the negative plates more rapidly than it could be removed by local action, since the chemical analysis showed decided evidences of lead peroxide on the plugs removed at  $\nu'$  from the negative plates. At  $\pi'$  (fig. 2) the E.M.F. of the accumulator under test became reversed, but rapidly recovered its original direction on stopping the discharge current, as seen from fig. 11.

down very rapidly whenever an attempt was made to use them, in spite of their having been charged in the intervals. As the E.M.F. was always in the right direction, it was supposed that the cells had become partially short-circuited in the removal, and it was not for some time that the true explanation of the refusal of the cells to do their work was discovered. The real fact was that, in fitting up the new laboratory, the leads from the dynamo to the switch had been reversed, so that the unfortunate cells were charged in the wrong direction every time the dynamo was turned on.

The preceding incident also forcibly illustrates the sort of attention that secondary cells may receive in practice, and shows the necessity for the P.D. and specific gravity being occasionally measured even in places where the study of the behaviour of cells is not the main business of the factory.

One of the great defects of the earlier specimens of the E.P.S. cells lay in the buckling of the plates. Mr. Capito tells us that it was Mr. Collet who noticed that all the plates generally curved in one direction, and who suspected that this arose from the unequal chemical action on the two sides of the last positive plate of the cell. Mr. Collet therefore proposed putting a negative

plate at each end of this cell, and this plan—which has been always followed since—of using one more negative than positive plate, has had much to do with removal of the buckling difficulty.

V.

EFFECT OF REST ON CHARGED ACCUMULATORS.

As the result of a number of tests described in our Edinburgh paper, we found that if E.P.S. accumulators be charged with 9 amperes and discharged with 10, a number of times without intermission, between the P.D. limits of 1·8 and 2·4 volts per cell, until the cells are brought to a perfectly steady "working state" the quantity efficiency is about 97 per cent., and the energy efficiency 87; further, that if the cells be fully charged until the P.D. per cell is 2·4 volts, and then be left perfectly insulated for 16 days, the next discharge between the fixed P.D. limits only gives out about 65 per cent. of the ampère-hours, and about 57 per cent. of the energy put in before the rest. Further, not merely is energy lost during the rest of an insulated accumulator, but for several subsequent charges and discharges between the same P.D. limits after the rest the storage capacity and the quantity and energy efficiencies are all lower than before the rest.

For the purpose of examining into what took place in an accumulator, which was left charged, a small E.P.S. cell was charged until the P.D. was 2·4 volts, and then the positive plates were withdrawn and put into another vessel containing dilute acid of specific gravity 1·2, the negatives being left in the vessel in which they were charged. Both sets of plates were covered up with gutta-percha hoods the edges of which dipped under the liquid, and to the top of each hood was fitted, gas tight, a vertical graduated glass tube closed at the top. The hoods and the glass tubes were first filled with liquid, and the amount of gas that came off from the two sets of plates was measured from day to day by watching the descent of the liquid in the tubes.

No gas was seen to come off from the positive plates, but in the case of the negatives gas came off very slowly at first, then more rapidly, and finally more slowly again. The following table gives a record of the amount of gas that came off from the negative plates, the gas, on analysis, being found to be hydrogen\* :—

Hydrogen Gas Collected from Charged Negative Plates after Removal of Positive Plates.

Date.	Time.		Cubic centimetres of gas collected.	Time of collecting gas, in hours.
	H.	M.		
November 15th ...	11	45	0	0
" 17th ...	10	0	2	46
" 20th ...	12	0	52	120
" 21st ...	10	0	72	142
" 22nd ...	10	0	87	166

If the lead of the positive plate be turned into lead sulphate by local action, 87 c.c. of hydrogen liberated corresponds with about 0·81 gramme of lead turned into sulphate. It is clear, then, that the lead of the negative plate is steadily being turned into some oxide or salt, and probably the loss of energy which we observed in the charged cell left insulated for many days was due to this local action at the negative plate. And further, as this action takes place apparently only at the negative plate, it is clear that in the subsequent discharge the cell will appear to be discharged before the positive plate is discharged, and charged up again without reducing all the lead sulphate on the negative plate. The local action at the negative plate while a cell is standing charged has, therefore, for the first few discharges and charges after a long rest, exactly the same effect as if a portion of the negative plate had been bodily removed out of the cell. Hence we see that the peculiarities observed by us in curves 8 to 23 in our Edinburgh paper may be explained by this defective behaviour of the negative plates.

VI.

CONSTRUCTION AND FORMATION OF E.P.S. PLATES.

The question arises why the E.P.S. accumulators are so constructed that the plugs in the positive plates contain some 48 per cent. more peroxide of lead than is required to be converted into sulphate in the normal discharge. Two explanations suggest themselves. One is that, since the granules of lead peroxide begin, as we find, to be coated with a protecting coating of sulphate early in the discharge, it is impossible, with the present form of plate, for the interior of each granule of lead peroxide to be converted into sulphate, and, therefore, it is necessary to employ nearly twice as much lead peroxide as is actually needed for the chemical action. Another reason is the fear of the positive plate crumbling to pieces if it be completely formed; and this reason Mr. Capito, who was formerly in the employ of the Electrical Power Storage Company, thinks, on the whole, is the more important.

In the construction of the original Faure accumulators, as well as of the early E.P.S. cells, both the positive and the negative plates were pasted with red lead ( $Pb_3O_4$ ), and formed together for a

period of some 50 hours. Later on litharge ( $PbO$ ) was used to coat the negative plate, red lead being used only for the positive one, and the plates were formed separately, the negative being much more formed at the works than the positive. Some time ago I was informed by a very competent authority that the following is the modern process of forming employed by the Electrical Power Storage Company :—

*Positive Plates.*— $8\frac{1}{4}"$  by  $7\frac{1}{4}"$  by  $\frac{1}{4}"$ . Two amperes per plate, or 0·028 ampère per square inch, sent for 18 hours.

*Negative Plates.*— $9"$  by  $9\frac{3}{4}"$  by  $\frac{3}{16}"$ . One and a half to two amperes per plate, i.e., 0·017 to 0·023 ampères per square inch, for 120 hours.

The actual time of forming either set of plates depends greatly on the length of stoppages during the formation. This is especially the case with the negative plates, therefore they endeavour to form the negatives for the 120 hours without any stoppage of the current. On the receipt of a cell from the Electrical Construction Corporation, the purchaser is requested to form it for 40 hours more with the ordinary charging current used in working, which is at the rate of 0·026 ampère per square inch.

Mr. Capito tells us that, when he was at Millwall, such periods of formation as 120 hours were not used; and he thinks that this may be due to the fact that formerly the plates were not dried after pasting and before formation, as they are at present. This drying hardens the plates and produces a better cell; but he thinks that, as the paste is itself mixed with sulphuric acid, there is probably some sulphating of the negative plates during drying, and that several hours in the subsequent formation are probably spent in reducing this sulphate.

The reason, we understand, for the manufacturers only forming the positive plates for 18 hours, and leaving the purchaser to form them for the remaining 40 hours, is that if positive plates be well formed and then dried for carriage, the plugs become loose, which is not the case if the positive plates be only slightly formed before drying.

We were interested in learning from Mr. Capito whether, while superintending the manufacture of many thousands of accumulator plates, he had ever tried pasting the positive with lead peroxide ( $PbO_2$ ) in order to avoid the necessity of having to form this salt electrically out of the red lead with which the positive plates are usually pasted. This idea of applying a paste of lead peroxide directly to the positive plate, he told us, he had tried, but that the method turned out a failure, from the impossibility of getting the lead peroxide paste to stick on to the grid even when some red lead was mixed with the lead peroxide. He also mentioned a very interesting fact—that whereas a paste of red lead mixed with dilute sulphuric acid of density 1·1 gives an adherent deposit on formation, on the contrary, a powdery deposit is produced if the density of the liquid used in making the red lead paste be 1·2. We understand the process that has shown itself the best is to use dilute sulphuric acid of density 1·1 for mixing the red lead paste, and dilute acid of 1·2 for mixing the litharge paste for the negative plates.

Discussion on "The Chemical Action of Secondary Cells," by Prof. W. E. AYRTON, F.R.S., C. G. LAMB, B.Sc., and E. W. SMITH, and on "The Working Efficiency of Secondary Cells," by the same authors and M. W. WOODS.

(Authorised abstract.)

In opening the discussion, Dr. GLADSTONE said he had been greatly interested in the points brought out by the authors, and in the account of the elaborate experiments described. He was rather surprised that taking out so many plugs from the cell had not greatly damaged it. The chemical results arrived at, he considered, confirmed the views put forward by himself and Mr. Tribe about nine years ago, as to the action of cells resulting in the formation and reduction of ordinary lead sulphate. Since that time, however, many statements had been made attributing important functions to sub-sulphates, but so far as he and Mr. Hibbert had investigated the matter, such statements had not been confirmed. They now believe that the so-called sub-sulphates are probably mixtures of ordinary sulphate and peroxide. Referring to the difficulty experienced by Mr. Robertson in analysing the powdered sulphate, he pointed out that ammonium acetate could be used for dissolving out the sulphate. Results obtained by this method showed the sulphate to be the normal one, and he did not think the solvent would alter any sub-sulphates if such were present. In his opinion there could be no doubt but that the sulphate surrounding granules of peroxide would act as stated in the paper and diminish the capacity of the cell. Speaking of the gas given off by the negative plate, he said the fact had been alluded to in a paper by Mr. Hibbert and himself recently published in the *Phil. Magazine*. They, however, had not observed the great differences in the hardness of plugs at different parts of the plates. This result, he considered, very important, and thought it would lead to a modification in the form of plates.

Mr. CROMPTON said that for some time past he had been working on the subject of secondary cells, and had arrived at results similar to those brought forward in the paper. One great advantage, however, of the results contained in the communications under discussion, arose from the fact that they were obtained from cells of a different type from those he had experimented on, for if he himself had brought the results before the Institution, it would have been thought that the actions were peculiar to his kind of cell. As regards the "gassing" of cells, he had found it due in a great

\* Since the preparation of this paper we have noticed that Dr. Gladstone and Mr. Hibbert, in their paper communicated this summer to the Physical Society, have also observed that hydrogen comes off from a charged negative plate of a secondary cell when left idle.

measure to light. Both sunlight and arc light increased this action, and quantitative experiments were now being made. He was glad to see the statements of the advocates of secondary batteries, as regards efficiency, had been confirmed. They had, he said, been accused of exaggerating their efficiency, and not without cause, for the cells themselves behave peculiarly, as, for example, the 105 per cent. quantity efficiency mentioned in the paper. Such results seem impossible, and showed the necessity of getting cells into what the authors had called "the steady working state." He regretted that "proof plates" had not been used in the experiments on the running down of cells. He had used them for a long time, and always found the negative discharged first. If, however, very thick negatives were used, there was no sudden drop in the potential difference such as indicated in figs. 2 and 3. In endeavouring to measure the resistance of cells with a view to determining the best proportions of plates and liquid, he had met with great difficulties, and he now believed that what is usually measured is of the nature of a back E.M.F.; this he supported by saying that the so-called resistance did not seem to vary either with the thickness of the plates or their distance apart, or with the density of the acid. During his investigations a rosy colouration of parts of the liquid had been noticed in some cells; the coloured portions may either appear as strata, lines, or in tree-like forms, and in some cases resemble the shapes of magnetic lines of force. These peculiarities, he hopes, may give some idea of the electric stresses and strains within the electrolyte. The recuperative power of discharged and reversed cells was very marked, for he had observed it in cells that were half charged in the reverse direction, and on cutting up the plates, layers of different materials could be seen. This fact shows how important it is to thoroughly charge cells of the Planté type during formation by reversals. Until quite recently, negative plates had been considered faultless, and the positives blamed for defects which were in reality due to imperfections in the negatives. He knew of no case in which positives had gone bad when their negatives had sufficient capacity; and for this reason the negatives ought to be made thicker or larger than the positives. "Sick cells," he said, get partially sulphated and the negatives run down; when the E.M.F. falls below 1.3, heavy sulphating of the positive occurs, and so-called "irreducible sulphate" is formed. In his opinion the reducibility or irreducibility is merely a question of its position, or of its contact or want of contact with the conducting material. In conclusion, he suggested that E.P.S. cells might be improved by reducing the size of the plugs so as to bring the active material down to the lead backing.

The discussion was adjourned to the 27th inst.

NOVEMBER 27th, 1890.

Mr. CROMPTON directed attention to three diagrams which he had prepared since last meeting. One of these showed the character of the colouration seen in the electrolyte when viewed from the top curved lines or shells, start from the positive plates and turn away as if repelled from the cell terminals. In one cell, which had its + and - terminals at opposite ends, the lines curved towards the middle of the cell, whilst in another, where the terminals were both at the same end, they bent towards the opposite end. The second diagram exhibited the influence of the rate of discharge on the capacity of a cell having eleven 5 lb. plates. When discharged at 1 ampère per plate, its capacity was 300 ampère hours, but at 6 ampères, only about half. The fall of volts was very sudden at the end of each discharge. The third diagram related to the discharge of an experimental cell containing seven 9 lb. plates, and showed that although the capacities were not very different from those of the 11 plate cell, the fall in volts was not nearly so sudden.

Mr. RECKENZAUN said the papers under discussion were very important ones, and contained much that had never been published before; many of the facts, however, were known to those engaged in the manufacture. The question of efficiency, he thought, was not likely to be settled, since, according to the authors, it may vary between 105 and 58 per cent., depending on the previous history of the cells. In his own experiments on the effect of prolonged rest, he had found a similar loss of efficiency, and he believed this to be due to sulphating of the negatives. The negatives were always played out first, and this defect could not be got over by making them abnormally thick, or by increasing their surface; for if thickening be tried, the interior is not acted on, whilst greater surface gives no advantage on account of the material being at different distances. To test the deficiency of negative plates, he had discharged cells as low as possible, and then put the positive with a newly charged negative; from these a fair E.M.F. and discharge were obtained. He had also tried amalgamated zinc instead of a newly charged negative, and got 40 per cent. of the original capacity. These facts account for the existence of 39 per cent. of Pb O<sub>2</sub> in the positive plugs when the cell was supposed to be completely discharged. In his opinion it would be better to say that the negatives discharged about 30 per cent. too soon. The negatives of Planté cells, especially those formed by the nitric acid process, soon lose their virtue, and this was attributed to the difficulty in removing all the forming acid. In the course of his remarks Mr. Reckenzaun said he had received a very interesting diagram from his brother in America, showing the E.M.F., current, density of acid, temperature of cell and of surrounding air, &c., during the charges and discharges of a secondary battery; this diagram he would place in the hands of the secretary.

A communication from Mr. HALL was then read. This related

to a pair of E.P.S. plates recently taken from the battery under his charge at the P. and O. Company's offices, where they had been in constant use for 6 years. During that period the cells had supplied about 150,000 ampère hours and were still in good condition, as was indeed evident from the appearance of the plates shown. In the working of the battery, the density of each cell had been carefully watched, and any defect promptly removed. His experience confirmed the observations of the authors on the effect of rest.

Mr. W. HIBBERT referring to the Edinburgh paper said he would first deal with the explanation of the high E.M.F. at the end of a charge, and its rapid fall on breaking the circuit. In a communication made to the Physical Society last June, Dr. Gladstone and himself had shown reason for believing this to be due to concentration of acid about the positive plate and subsequent rapid diffusion, and he thought the results plotted in fig. 6 of the paper under discussion, showing the effect of making and breaking the circuit of a charged cell on its E.M.F. and P.D., were consistent with this idea. Further on in the same paper the authors say that the concentration hypothesis will not explain the rise of P.D. in a cell discharging after a long rest; on this point he, Mr. Hibbert, said that the reactions in such states were very complex, but still he thought it would be possible to find an explanation of this phenomenon based on similar lines. Referring to the latter paper, he thought the authors had rather exaggerated the effect of peroxide on the negative plate in causing the volts to fall, for in his own experiments only a small quantity was formed. The simultaneous weakening of the acid round the plates would tend to give a rapid fall in the E.M.F. and the effect of both these actions must be studied if the subject is to be properly understood.

Dr. E. FRANKLAND said he had read the papers with great interest and considered them most important contributions on the subject. In one place the authors deplore the lack of knowledge of the chemical action in cells, and not without reason, he, however, thought physicists were more to blame than chemists, for the physical actions could be readily determined, whereas the chemical changes present formidable difficulties. The substances used and produced were mixtures, and it was very difficult to separate and analyse them, without producing decompositions. A valuable part of the communication was that relating to the quantity of Pb O<sub>2</sub> formed and decomposed during the working of cells. On this point he thought the values put down for Pb O<sub>2</sub> may be either the sesqui- or the three-quarter-oxide, and, in fact, the crux of the whole subject lay in the exact nature of the compounds formed. Dr. Gladstone and himself had apparently arrived at different conclusions, but their differences might admit of explanation, if care and time were taken in considering the matter. Another important point was the quantity of SO<sub>2</sub> absorbed during discharge, viz., 3.08 grammes per ampère hour. If this be translated into hexabasic acid, which he believed to be present, it gives 5.71 grammes. From his own experiments on a 10-plate cell, he had found about 4.7 grammes of hexabasic acid absorbed per ampère hour, whilst discharging at an E.M.F. averaging 1.9 volts, but when the cell was run down and discharged at an E.M.F. averaging 0.3 volt, he found the rate about 3.3 grammes. He did not wish to put these numbers in conflict with those obtained by the authors, but he was strongly impressed with the idea that the two different quantities 4.7 and 3.3, pointed to the existence of two distinct chemical reactions, one resulting in an E.M.F. of about 2 volts, and the other of .3 volt.

Mr. F. KING said the results of the tests were very gratifying to the makers of cells. He commended the skill and ingenuity displayed in devising the automatic apparatus, for the labour involved in working a laboratory day and night without such apparatus is enormous. The inequality of current distribution over the surface of the plates was, he said, well known, and the hanging type of cell was devised to remedy this defect. The first form of this type was abandoned, but more recently they had made another form, one of which was exhibited at the meeting. The current is led into the positives at two points on the top and leaves the negatives at the bottom. With this cell they had doubled the normal rate of discharge without diminishing the capacity and also obtained a longer life. Moreover, the loss of capacity for high rates of discharge, due to the shrinkage of the negative paste and which is so marked in ordinary types, had been avoided. The positive plates somewhat resemble those of the Tudor cell, having deep horizontal grooves along each side in which the active material is placed. The negatives are made according to Sellon's invention, in which a kind of double grid is used, the parts being displaced diagonally so that each plug on one side communicates directly with four plugs on the opposite side and through them with every other plug in that division of the plate. This construction causes any shrinkage of the paste to bind itself more firmly on the grid. As a result of tests on the new cell it has been found that the capacity is greater after 500 or 600 discharges than at the beginning, whereas that of ordinary cells is considerably reduced by 400 discharges. The life of negative plates he believed was not well understood, but with reference to positives he said that those used on tramcars (nine plates 8" x 9½") had a useful life of 70,000 ampère hours. After one year's use their capacity is reduced 83 per cent. Speaking of the resistance of battery connections, he pointed out the advisability of burning the lugs together so as to give as complete a metallic surface as possible. Respecting the pasting and formation of E.P.S. plates, referred to in the second paper, he said that the particulars there given were totally wrong.

Mr. SWINBURNE thought there had never been any solid reason for doubting the formation of normal lead sulphate. The old

ideas about reduction and oxidation that had obscured the subject until Dr. Gladstone and Mr. Tribe brought people to order about eight years ago. The difficulty of reducing ordinary sulphate electrically had been given as a reason why it could not be formed, but now its reduction or non-reduction was known to be a mere question of making contact with it. Seven years ago he had brought forward a theory that the sulphate is not a secondary product at all, and that the output of a cell is mainly dependent on the affinity of sulphur for lead. This, together with the other chemical actions, leaves some E.M.F. to be accounted for by Peltier effects, and these effects would show in the temperature coefficient. He was not aware whether calorimetric data had been obtained for the subsulphates which Dr. Frankland supposed to be present, but, if so, then by working backwards evidence for or against their existence might be procured. The action of finely divided lead on sulphuric acid had, he had, been known for years, and this limited the best strength of acid to about 1 in 4. As regards the equilibrium between the plates of a cell, he was inclined to attribute this either to the absence of  $PbO_2$  from the positive, or of spongy lead from the negative, rather than to the presence of  $PbO_2$  on both plates. He also thought the percentage of material really active was much less than that stated in the paper, for in some experiments of his own he had only found about 8 per cent. useful. Speaking of Mr. Crompton's colour observation, Mr. Swinburne said they were due to ferric acid formed by the action of  $PbO_2$  on iron salts in the commercial acid. In his opinion the virtue of sulphate of soda had been greatly exaggerated, and he believed its action to be due to its enabling bad contact sulphate to be reached more easily.

Sir D. SALOMONS said he had noticed colouration in one or two of his cells, but had attributed them to impurities. The unequal action on different plugs had been to him a subject of common remark, and he had taken steps to equalise the distribution of current by burning on strips of lead, with good results. The bending of negatives could be prevented by building up the sections rigidly. His experience with soda differed from that of Mr. Swinburne, for he had found caustic soda, in the proportion of one ounce to six gallons, very advantageous. Cells supplied with this electrolyte had been left charged for six weeks without injury, and had commenced to boil freely ten minutes after the charging current was started. With ordinary acid, two or three hours charging would be required to produce the same results. In his opinion, makers give extreme limits for the so-called normal working rates of cells, and if these were divided by 2 or 3, better results would be obtained, and would be cheaper in the long run. As regards efficiency, he thought 70 per cent. to be a very fair average. The large amount of  $PbO_2$  not acted on, resulted from the interior of the plugs being, as it were, waterproofed by the sulphate outside. On this account thick plates possessed little or no advantage. Increasing the quantity of electrolyte, however, gives more capacity up to a certain point, but when the plates are put far apart the loss of volts becomes serious. Speaking of pasting positives with  $PbO_2$ , he said he had made good plates in this way by using very strong acid (nearly pure) in making the paste.

Mr. BERNARD DRAKE, whilst adding his testimony to the value of the papers, thought he ought to mention one or two points of detail which might lead to wrong conclusions. For example, the loss of efficiency due to rest might lead clients to suppose that their cells ought to be used even when they were away from home. This, he said, would be a great mistake, for the loss of capacity is due to the negatives; whereas the repairs were chiefly restricted to the positives, whose lives are inversely proportional to the amount of use. In a paper read before the British Association in 1886, he and Mr. Gorham had shown that the whole success of storage cells depended on whether the positives could be made to last a reasonable time, and to effect this it had been found necessary to overcharge them. The actual plates sent by Mr. Hall from the P. and O. offices had been badly sulphated some time ago, and were condemned; he, however, recommended overcharging, with the result now known. In these cells the density of acid used to be from 1,350 to 1,400, and although he did not now recommend such a high specific gravity, yet he thought the subject required more attention than it had received. As to the proportions of the plates, he said the negatives were intentionally made to give out first, so that the positives might not be run down, for a kind of protecting coating is formed on the positives by charging and this is removed by discharging them below a certain point. If this coating is continually reformed the plates expand and buckle and the plugs eventually drop out. Speaking of the cooling action during discharge and also after charging has commenced, he did not see any explanation excepting perhaps that it might depend on the same cause as the rise of specific gravity which occurs after a charging has stopped. This he had found to be due to the heavy acid formed during charging falling to the bottom of the cell and afterwards diffusing into the general body of the liquid, thus affecting the hydrometer. In this connection he enquired whether the temperature was taken at the top or bottom of the cells. The rise of E.M.F. during the first part of a discharge after rest he attributed to the surface of the negatives being coated with a sulphate which was reduced by the discharging current. In reference to the shrinkage of negatives mentioned by Mr. King, he said that in order to avoid blistered negatives a mixture of litharge and sulphate had been used for pasting instead of litharge only. This method although it prevented blistering, necessarily left the plugs of a porous nature, and was liable to permit shrinkage.

The discussion was adjourned to the 11th December.

## LEGAL.

**Watt v. Maxim-Weston Electric Company.**—The matter in dispute between Mr. Watt and The Maxim-Weston Electric Lighting Company were at last settled, on Monday last, by arrangement between the parties. Mr. Watt had claimed £1,623 for salary, commission on the profits of the company, compensation for wrongful dismissal from his position of managing director, payment of rent, and other moneys. A cross action was brought by the company, and it was alleged that Mr. Watt had been general manager upon whose representations the other directors and the auditors relied, and that the accounts purporting to be profit and loss were made out by him. It was also stated that these accounts were untrue, having been made to appear as large as possible so that he could draw 5 per cent. commission, and that upon them plaintiff received larger sums than he was entitled to. Further, it was alleged that he had sent out goods to agents abroad which were not sold, but which were treated by plaintiff as actual sales, and also that bad debts had been entered as good. At Mr. Justice Romer's suggestion the two actions were treated as one and tried together.

The hearing of the case lasted three days, and the judge finally suggested that this was a case where, instead of going through the items one by one, a general sum should be arrived at between the parties, and proposed that he should rise for a short time with a view of counsel seeing whether that could be done.

Counsel on both sides assented to the suggestion, and, after an absence of half-an-hour, his lordship returned into Court, when

Mr. Rigby announced that they had arranged everything as between the company on the one side and Mr. Watt, whether properly raised in actions or not. Watt was to pay the liquidator certain sums standing to his credit in respect of shares purchased by the liquidator, and £330 14s. which stood to a joint account, would be paid to the company, together with the sum of £669 6s. standing to a joint account, and making up £1,000. The actions had got very much mixed up together, but Mr. Watt would pay the taxed costs between party and party in both actions. Mr. Watt would not pay any costs in the winding-up, but included as proper costs in the action were the costs of the motion, directed by the Registrar. The matter was a final settlement of all claims down to this date between the company and the liquidators on the one side and Mr. Watt on the other, whether properly raised in these actions or not, so as to prevent any further litigation.

## REVIEW.

*Electric Light, its Production and Use; Embodying Plain Directions for the Treatment of Dynamo-Electric Machines, Batteries, Accumulators, and Electric Lamps.* By G. W. URQUHART. Fourth Edition. London: Crosby, Lockwood and Son.

The third edition of this work was noticed by us in January of this year, and in reprinting a fourth, the opportunity has been taken of adding two new chapters, "Notes on Ship Lighting," and "Electric Light Wiring Tests." Twelve new illustrations have also been added. Mr. Urquhart's books are written for workmen, and like most works of the kind, are not free from errors, when judged from a scientific standpoint. They are, however, better than most popular works of the same class. Referring to the new chapters, the author's ideas of insulated cables are decidedly crude; and his descriptions of the methods of testing are not likely to afford much help. A mistake is made in explaining the lamp test for earth leakage. We fear that a good deal of the information in these chapters has been derived from published papers and articles rather than from practical experience.

**Obituary.**—M. A. Bède.—We regret to announce the death, in Brussels, of M. Armand Bède, son of M. E. Bède, the well-known Belgian electrician and engineer. The deceased was one of the most distinguished engineering students at the Brussels Polytechnic School, and had already made himself a name by important electrical installations in Russia and Italy and also in Belgium, where he was obliged to return three years since on account of weak health. This gentlemen's death is the cause of much sympathy among Brussels engineers, who had for several years unanimously elected him their vice-president.

## ELECTRIC LIGHTING PROGRESS IN LONDON.

THE paper on this topic, read by Mr. Frank Bailey, before the Society of Arts, is a summary of the present position of things. The paper contains a general history of electric lighting in London, with details of systems adopted. Private plants work about 80,000 32-watt lamps in addition to the supply companies. Mr. Bailey showed table, a copy of which Mr. Bailey has kindly sent us, will be found very interesting:—

## ELECTRIC LIGHTING COMPANIES IN LONDON.

Name of company.	Capital (nominal).	Number of years in existence.	Stations.	Total H.P. engines.	Number of lamps equivalent to 32-watt lamps now connected.	System.	Length of conduit, pipe, or s.w. cable run of main.	Lamps per m. l.c.	Meters.	Districts.
	£						Miles		Number.	Type.
St. James, St. George, Chelsea, Rotherhithe, Bermondsey, St. Mary, Newington, Lambeth (part of), St. Martin's-in-the-Fields (part of). Bill, 1889 ...	1,250,000	5	Deptford	...	38,000	Alternate current transformers (Ferranti)	...	...	136 Ferranti (mercury)	Parishes of:— Clerkenwell (part of) St. Martin's

			Total		179,060 lamps equivalent to 32 watts each.					

## PARLIAMENTARY NOTES.

*Railway Signalling.*

IN the House of Commons, on Friday, in reply to Captain Price, Sir M. HICKS-BEACH said: The subject of automatic electric signalling on railways has frequently engaged the attention of the Board of Trade, and further inquiries are now being made. There are many difficulties to be contended with, and all I can say at present is that the matter will continue to receive attention. It may be added that the Norton-Fitwarren collision would not have been prevented had the system, as hitherto carried out, been in force there.

*Licences for Telephone Exchanges.*

In the House of Commons on Monday, Dr. CAMERON asked the Postmaster-General whether, in view of the fact that the patent for the telephone in use by the company which possesses a practical monopoly of telephonic communication in Great Britain had now expired, and in view of the numerous complaints on the part of the public as to high rates and faulty service resulting from that monopoly, he would, with as little delay as possible, make known his decision as to applications for licenses submitted to the Post Office by proposed competitors desiring to introduce loud-speaking and long-distance telephones, and other forms of improved instruments.

Mr. RAIKES: In reply to the hon. member, I have to say that I trust that I may be able at an early date to announce the decision of the Government with regard to licenses for telephone exchanges. It should be borne in mind that the patents for the more important telephones have not expired, and do not expire until July in next year.

*Electric Lighting in London.*

Mr. R. CHAMBERLAIN asked the President of the Board of Trade whether his attention had been called to the long-continued default of the Chelsea Electric Supply Company to furnish the statutory current of 100 volts, and to the serious loss of illuminating power sustained by consumers in consequence; and whether he would take steps to compel this company to keep faith with the public or forfeit their concession.

Sir M. HICKS-BEACH: Last winter the hon. member complained to the Board of Trade of the deficiency in the standard pressure of the current supplied by this company. The Board of Trade communicated with the company, and were informed that the cause of complaint had been removed. Under the regulations imposed upon the company under their order they are bound to declare to the consumer the constant pressure at which they propose to supply him with energy, and the variation from the pressure so declared must not exceed 4 per cent. under a penalty not exceeding £5 for each default, and a daily penalty not exceeding £5 so long as the default continues. If the regulations are not complied with, it is open to the consumer to proceed against the company for penalties.

Mr. R. CHAMBERLAIN asked whether the right hon. gentleman's attention had been called to the fact that the variation mentioned was taken advantage of in order to supply the consumers, not with an average of 100 volts, but of 97, in that way taking advantage of the concession of the Board of Trade.

Sir M. HICKS-BEACH: However that may be, if the company are in default, the consumers have their remedy. It is not for the Board of Trade to enforce the law.

Mr. R. CHAMBERLAIN: I understand from the right hon. gentleman that we have no remedy unless they get below 96, the 4 per cent. referred to in the answer just given.

Sir M. HICKS-BEACH: Yes, sir, that is so.

**Lighting of Friedek.**—The streets of this small town in Eastern Silesia were lighted electrically for the first time on the 12th ult.

## NOTES.

**The Paris-London Telephone Line.**—It is announced that the cable will start from the French coast near Calais and terminate at Dover, from which town the line will be carried overhead to London. The apparatus in Paris will be provisionally installed at the Bourse, and will subsequently be erected permanently in the Hotel des Telephones in the Rue Gutenberg as soon as that building is completed. The telephone will be available for use both day and night, including Sunday, notwithstanding, as a French paper says, "the rigorous English custom which desires all work to repose on that day." It is believed that the charge for conversation will not be less than 20 francs for five minutes. If all goes well, the line is to be opened on the 15th of February.

**Count Mattei's Coloured Electricities.**—A friend writes:—"Referring to the remarks in your journal of 28th ult. on Count Mattei's remedies, you are wrong in thinking that the Count attributes any of his undoubted success to electricity. He certainly calls his system "Electro-homœopathy," but merely because many of them are quick in action as compared with homœopathy proper, but has nothing whatever to do with actual electricity. I think it is a pity to condemn a system which possibly may have some merit—merely on an erroneous idea."

**Portsmouth New Town Hall.**—The Portsmouth New Town Hall, which has cost £140,000, has an installation of the electric light, and the illumination of the large hall, in which Madame Patti sang on her recent visit to the town, has given great satisfaction. In order to provide efficiently for charging the accumulators with electricity, the Town Hall Committee have been advised that another dynamo should be erected. The tender for this dynamo was £260, but as there will be some other work connected with it, the Town Council at a meeting last week authorised the committee to expend a sum not exceeding £300.

**Lacombe and Company.**—Mr. Holland Dell announces that in consequence of increase of business, Messrs. Lacombe & Co. have taken ground-floor premises at 7, Carteret Street, Westminster, where a sufficient stock will be kept of carbon goods to meet pressing demands at short notice. Attention is drawn to the fact that Messrs. Lacombe & Co.'s works have been enlarged, and the plant increased.

**Glasgow Telephone.**—The new directory of Glasgow subscribers to the National Telephone Company is just published, and contains a notice that on and after the 1st January next the existing rate of £15 per annum for the first connection to the exchange, within the half mile radius, will be reduced to £10. Subscribers private houses, if within a radius of one mile from the nearest switch room, are connected for an annual charge of £8 10s.

**Engineers' Pocket Books.**—We have received copies of the following publications for 1891.—"The Practical Engineer Pocket Book," published by the Technical Publishing Company, Manchester; and "The Mechanical World Pocket Book," published by Messrs. Emmott and Co., of Manchester and London. Both contain a number of tables and items of information the greatest service to engineers, mechanics, draughtsmen, and others.

**The National Telephone Company and Mr. Erskine Muirhead.**—We have received some further letters from Mr. Muirhead, but as they do not contain matter of interest we must decline to print them, and must close the correspondence, which reveals a state of affairs, on the one hand decidedly high-handed, and on the other decidedly deficient in dignity of tone.

**Photography.**—According to the *Amateur Photographer*, Sir David Salomons, Bart., takes a great interest in photography, especially in connection with the Tunbridge Wells Amateur Photographic Association.

**Telephony between Germany and Switzerland.**—Political difficulties have hitherto prevented the establishment of telephonic communication between the towns on the Swiss-German frontier. These obstacles have now been removed, and telephonic lines will shortly be erected.

**High Pressure Alternating Mains.**—*Industries* says: "Reports have of late been freely circulated that the Deptford electric light mains show a very much higher pressure at the London than at the Deptford end. Several eminent scientific men are said to be investigating this phenomenon. We should like to know more about this apparently impossible effect. We may mention another fact, which may be foretold on theoretical grounds, and which, while being apparently similar, is really quite different from that referred to above. For example, if a dynamo is excited to give, say, 5,000 volts at the terminals before the mains are connected, it will give considerably more directly they are thrown on, especially if the load is very light, but the increased pressure will be at Deptford as well as in London. The rise of pressure can be roughly calculated beforehand if the particulars of the dynamo and mains are given. A higher pressure in London than Deptford at a given time appears quite incapable of explanation with our present knowledge."

**Tapping Holes in Porcelain with Fine Threads.**—Messrs. Taylor, Tunnicliff & Co. send us the following note:—"Messrs. Bullers appear to have misconstrued the remarks on the above question in your issue of November 14th. It is well known that coarse threads in porcelain have for a considerable time been made in large quantities by the various firms engaged in the trade; but the finer pitch of Whitworth threads of  $\frac{1}{16}$ th to  $\frac{3}{8}$ th diameter are but of very recent introduction, and present considerable difficulty in production in the stereotyped methods, as well as uncertainty in the finished articles. All we claim is that we have invented a machine which ensures a solid thread of fine pitch and regularity of size, much superior to the ordinary hand-made article. We do not think Messrs. Buller will deny that this requirement is of but recent introduction, and has not been in use the number of years their remarks would have you to suppose."

**Electropathic Belts.**—It is surprising to find papers, edited by men who have graduated at Oxford or Cambridge, allowing their columns to be prostituted by the advertisements of so-called medical electricians. The *Whirlwind*, the organ of the Hon. Stuart Erskine and Mr. H. Vivian, contained on the 22nd ult. what, at first sight, appeared to be an article referring to the Rev. E. F. Shaw. The eighth line, however, showed conclusively that the article, which was prominently given on the front page of that paper, was only an advertisement of the "Eminent's" electropathic belts. The editors of the *Whirlwind* cannot be congratulated on the results of their schooling.

#### Recent Interruptions and Repairs to Submarine Cables and Land Lines, up to 25th November, 1890:—

Cables.	Interrupted.	Repaired.
Suakim—Perim ...	12th Sept. ...	Still interrupted.
Cape St. Jacques—Thuanan	21st Oct. ...	27th Oct.
Porthecurno—Vigo ...	1st Nov. ...	20th Nov.
Vigo—Lisbon... ..	1st Nov. ...	17th Nov.
Mozambique—Louvenço-Marquez ...	11th Nov. ...	11th Nov.
Mozambique—Louvenço-Marquez ...	18th Nov. ...	19th Nov.
Trinidad—Demerara ...	18th Nov. ...	Still interrupted.
Salina Cruz—Libertad ...	25th Nov. ...	" "
Land-lines.		
Moulmein—Bangkok ...	22nd Oct. ...	24th Oct.
" " " ...	9th Nov. ...	10th Nov.
Dakar—Yof ...	27th Oct. ...	29th Oct.

**The Electrode.**—Mr. D. Hillock, of 58, Berners Street, W., believes he has made an important discovery. He advertises "The Electrode," by the use of which "the blind recover their sight, the deaf their hearing, and those who have lost their voice regain it." Electricians do not see, neither do they wish to hear, but they raise their voices to protest against the use of such bogus statements.

**The City Lighting.**—Why the City papers and others grumble about the delay in the electric lighting of the City cannot be imagined. A man or a company is not likely to complete a contract before the close of the stipulated period without receiving some pecuniary benefit; and yet people talk about the "knowing City men."

**Reduced to the Ranks.**—Mr. J. Swinburne has lost his German "professorship," which he only recently gained. The *Elektrotechnische Zeitschrift* has been pleased "to undress" the (word) "professor."

**Fire Brigade Failings.**—A representative of *Trade, Finance, and Recreation* has had an interview with Captain Arthur Shean on "Fire Brigade Failings." We are acquainted with Captain Shaw and with Mr. Simmonds, his second in command, but we scarcely think that the author of the following remarks can be attached to the London Fire Brigade; if so, he might with advantage take a course of lessons on elementary electrotechnics at one of the technical colleges:—Q. "Have the fire brigade any special method of dealing with fires caused by the imperfect insulation of the electric light?" A. "No, they have neither received any instructions with reference to the matter, nor been provided with proper implements. A man ought not to cut an electric wire with an ordinary hatchet unless he wears an India-rubber glove, and yet such a glove does not exist in the whole brigade. I was at a theatre the other night which is lighted with electricity, and I asked the fireman what he would do if the electric light were to ignite any part of the building? I was astonished to find that he knew nothing about it, and that there was nothing in the theatre in readiness for such a calamity. One of these days we shall have a great sensation, because a fire caused by electricity is more serious than an ordinary fire, since you have the ignitable force fitted all over the building. Up to the present there have been several accidents in London through electric lighting, and surely we ought not to wait till some great disaster occurs before attending to the subject." What does the gallant Captain mean by the ignitable force being fitted all over the building? Is not gas fitted all over a building, and when a rupture occurs in an electric conductor does not the ignitable force vanish at once?

**Guaranteed Accumulator Maintenance.**—The General Electric Power and Traction Company, Limited, is now offering to tramway companies to supply cars and the electrical equipment, and to maintain the motors, switches, gearing, and accumulators at a mileage rate; the tramway company operating the road at their own expense. The result of the experience at Barking enables this company to undertake electric plant maintenance at such a price that, including the cost of generating the power, &c., traction by accumulator cars will be less costly than that of horses; and in northern towns, where coal is cheap, the cost will be much below that of horse traction. A recent improvement in the "E.P.S." accumulators warrants the statement that this form of traction on average roads must of necessity be in all cases less than that of horse traction. The company is at present in negotiation with some of the largest tramway companies in the country on these lines. The company is also busily employed in the manufacture and erection of mining plant for many of the principal collieries in the country. This branch of the work is rapidly developing.

**Tramway Companies and Electric Traction.**—The North Metropolitan Tramway Company has received the consent of the London County Council to run electric cars over the northern portion of its line, controlled by the Council, during the term of 7 years. The tramway company has also given notice of a Bill which it intends to introduce into Parliament, asking Parliament to compel the local authorities to conform to the Act as passed last session, giving the tramway company the full term of seven years guaranteed by the Act. At present, the West Ham local authorities decline to grant more than one year's license, subject to 24 hours' notice. It is, hoped, however, that they will now follow the example of the London County Council, and grant the full term of the license, enabling the tramway company to equip two roads on which their lines run, and which are in the parish of West Ham, and on which it is the intention of the tramway company to place electric accumulator cars.

**Automatic Fire Alarms.**—On Wednesday, December 3rd, there took place in the arsenal of the Great Lake, Genoa, in presence of the territorial director and vice-director of artillery and of various officers of the artillery and the military engineers, the first experiments on the auto-electric fire alarm and signal thermometer on the Bieberstein-Fois system, which the inventors offer in homage to the king. The experiments succeeded surprisingly: the apparatus combined the sensitiveness of the mercurial thermometer and gave instantaneous alarms at whatever temperature, which result is due in part to the excellent workmanship of the establishment for instruments of precision, A. E. Conti (Sant Algo, Genoa), which may compete for such kind of work with the first foreign houses.

**Ironmongers and Sale of Electrical Fittings.**—Our contemporary *Ironmongery*, "to give further effect to oft-repeated counsel that ironmongers should take up electrical fittings as a substantial branch of the trade," purpose commencing in the January number a series of practical articles on electric installations, for the guidance of those who intend taking up the sale of electrical accessories.

**The London Electric Supply Corporation.**—We understand that Mr. Ferranti has shut off the supply of electrical energy to the customers of this corporation, and that it may be two or three weeks before the current will be turned on again. We believe that the mishap, to which we refer in our leading pages, is mainly the cause of this temporary stoppage. With the apparatus once again in working order, Mr. Ferranti does not intend to allow a recurrence of the recent disaster.

**Underground Cables.**—We have received two important communications bearing upon the letter in our last issue, "Notes on Electric Lighting from Central Stations." The first is from Mr. Alfred E. Mavor, general manager to the Fowler-Waring Cables Company, and the second is penned by Mr. Ferranti, and both give direct denials to the statements contained in the copy of the India Rubber and Gutta-Percha Company's letter. We shall publish these in our next issue.

**A Correction.**—In our note on Theatre Lighting last week we should have stated that Messrs. C. E. G. Gilbert & Co. had secured the contract for lighting the Globe Theatre, the name of Messrs. Dickinson being an error.

**Montevidean and Brazilian Telegraph.**—An extraordinary general meeting of the Montevidean and Brazilian Telegraph Company, Limited, was held on Wednesday at Langthorn House, Copthall Avenue, Dr. Cameron, M.P., presiding, when resolutions passed at an extraordinary general meeting held on November 25th, and reported in our issue of November 28th, were confirmed.

**Popularising the Telephone.**—The *City Press* says: "With the New Year it is understood that the Post Office authorities will make new arrangements for the public use of the telephone, tending to popularise the instrument and bring it into general employ." We understand that no important step will now be made by the authorities, at least until after the transmitter patent of Edison expires next July.

**Marriage of Captain Khotinsky.**—The marriage of Captain A. de Khotinsky, of Rotterdam, the inventor of the Khotinsky electric system, with Mrs. M. Fuller, widow of the late P. Fuller, Esq., of Blackheath, Kent, was celebrated in London on the 24th ult. We learn that Captain de Khotinsky and his bride sailed, per ss. *Teutonic*, for a tour in the United States, where he intends to establish a lamp factory at Boston for the manufacture of the Khotinsky lamp and other appliances used in connection with his system.

**The New West India Cables.**—The new cable laid by the *Westmeath* for the Société Française du Télégraphes Sousmarin's between Port de France, Martinique, and Paramaribo, Dutch Guiana, was opened on the 9th December for international traffic. The provisional tariff established by the Société Française des Télégraphes Sousmarins is an addition of 2.20 francs per word to the existing rates to Martinique. The Anglo-American Company notifies that in consequence of certain misunderstandings which have arisen with respect to telegrams sent by post from Mole-St. Nicolas to Port-au-Prince, and from Colon to Barranquilla, it is necessary to remind the public that these telegrams carry, in addition to the tariff, a postal tax of 1.25 francs.

**University College, Aberystwyth.**—The workshop accommodation of the physical laboratory in the University College of Wales, Aberystwyth, has recently been considerably extended, and arrangements are being made for a course of instruction in electrical engineering. The recent additions include a high speed gas engine, specially adapted for electric lighting, a Crompton dynamo (shunt and compound wound), and a Crompton D.D. arc lamp, &c.

**Extension of Telephony in South Wales.**—The South Wales Telephone Company have opened communication with Port Talbot.

**Improving Insulation.**—Perhaps some of our readers may know whether the electrolytic method of improving insulation, described in our correspondence columns by Mr. A. A. Campbell Swinton, has ever been previously adopted.

**American Company Dividends.**—The New York Edison Electric Illuminating Company has declared a quarterly dividend of 1 per cent., payable January 15th, with an extra 5 per cent. in scrip, convertible upon an increase in the capital stock, and bearing the same interest as the present stock; Bell Telephone, 3 per cent., all payable January 15th.

**Electric Lighting at Bognor.**—At a meeting of the Local Board, last week, a letter was read from the secretary of the Electric Trust, Limited, stating that the company were prepared to enter into negotiations with a view to undertaking the public lighting of Bognor by electricity. They would be prepared to supply a 16-C.P. lamp for £4 per annum, and enter into a three years' agreement. The system would be similar to that adopted at Woking, and the company invite the board to visit the works at that place, when their system of working would be fully explained. The matter was eventually referred to a special committee.

**Electric Lighting Fatality.**—Yet another victim is added to the long list of fatal accidents due to electric lighting currents. At Chicago, on the 2nd December, a linesman was instantaneously killed from coming in contact with an electric light wire. Details of the mishap are not yet to hand. So long as bare wires are employed, or indifferent insulation made use of, undertakers may rely on electric lighting for some addition to their business.

**Cable Subsidy.**—In a paper read before the Royal Colonial Institute on November 11th, Mr. George S. Mackenzie stated that the German Government had granted to the Eastern and South African Telegraph Company an annual subsidy of £5,000 for the cable which this company has just laid between the Island of Zanzibar and Bagamoyo, the capital of the German Protectorate on the East African Coast.

**Good News for Wine Bibbers.**—A new cure for gout has, according to the *Matin* of Paris, been discovered by Mr. Edison, the American electrician. It is stated to consist in the simultaneous use of lithine and electricity.

**City and South London Railway.**—It is rumoured that this railway will be opened on Monday for public traffic.

#### NEW COMPANIES REGISTERED.

**Marine and General Automatic Company, Limited.**—Capital £20,040 divided into 4,000 ordinary shares of £5 each and 40 founders' shares of £1 each. Objects: To purchase from W. T. Wright Thackeray, Isaac Hurn and John Davies, the patent rights of improvements in automatic electrical tell-tale apparatus, with power to purchase other inventions relating to marine and other engines. Signatories (with one ordinary share each): J. Davies, East Sheen; G. J. Bridges, Chepstow Rise, Croydon; S. Bradford, Kingston-on-Thames; Isaac Carr, Walthamstow; T. E. Colcote, 5, Lancaster Place, Strand; \*Lieut. St. John, R.N., 119, Confield Gardens, West Hampstead; H. C. Bridges, 20, Hart Street, W.C. The first directors are Lieut.-Colonel F. Despard, Anthony McKeand, Lieut. St. John, and Thomas Wilkins, C.E. Remuneration—chairman £3 3s., and each director £2 2s., for every meeting attended. Registered 29th ult. by Andrew Wood & Co., 8, Gt. James Street.

**Plenty & Son, Limited.**—Capital £25,000 in £10 shares. Objects: To take over the business of marine, general and mechanical engineers, carried on by Plenty & Son, at the Eagle Iron Works, Newbury, Berks. To carry on the business of electricians and as manufacturers and dealers in apparatus and things required for the generation, distribution, supply, accumulation and employment of electricity. Signatories (with one share each): \*E. P. Plenty; E. P. Plenty, Jun.; John Mason, Newbury, Berks; Laurence Read, 18, Hanover Street, W.; J. Clarke, Chieveley, Berks; \*Earl Russell (electrical engineer), Amberley Cottage, Maidenhead; \*H. Wethered, Clifton, Bristol. The signatories denoted by an asterisk are the first directors. Qualification 50 shares; the company in general meeting will appoint remuneration. Registered 29th ult. by R. Jordan, 120, Chancery Lane.

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**"Electrician" Printing and Publishing Company, Limited.**—The annual return of this company, made up to the 28th October, was filed on the 3rd inst. The nominal capital is £10,000 in £10 shares; 940 shares are taken up, 800 of which are considered as fully paid. Upon 140 shares the full amount has been called and paid.

**Woodhouse and Rawson Electric Construction and Maintenance Company (Lancashire, Yorkshire and Cheshire), Limited.**—The final winding up meeting of this company was held on the 25th ult., when an account was given, showing the manner in which the winding up has been conducted and the property of the company disposed of. The notice was filed on the 4th inst.

**Electric Tramways, Construction and Maintenance Company, Limited.**—The annual return of this company, made up to the 2nd July, was filed on the 3rd inst. The nominal capital is £250,000 in £1 shares, but although the company has been in existence since the 8th December, 1886, only seven shares have been taken up, and upon these no call has been made or paid.

**Electric Wiring and Fittings Company, Limited.**—An agreement of 24th ult., filed on the 5th inst., between Latimer Clark, Muirhead & Co., Limited, and this company, provides for the cancellation of 1,500 fully paid shares allotted to the former under an agreement of 22nd November, 1889.

**Atlas Engine Company, Limited** (engineers, contractors and electricians).—The statutory return of this company is made up to the 2nd September. The nominal capital is £12,000, in £1 shares, but only seven are at present taken up, and upon these the full amount has been called and paid. Registered office, Poole, Dorset.

**Gordon Electric Traction Syndicate, Limited.**—An agreement of 18th August between John Gordon, of 13, Nettleton Road, New Cross, electrical engineer, provides for the purchase from him by the company of a system of electric street car traction, provisionally protected on the 5th May, No. 6,083. The purchase consideration is £600 in fully paid £10 shares. Mr. Gordon is appointed managing director for two years, at a salary of £4 per week.

**Sheffield Telephone Exchange and Electric Light Company, Limited.**—An agreement of 9th September (filed 6th October) provides for the taking over, by this company, of the business carried on there by the company in liquidation of the same title. The new company will discharge the debts and liabilities of the old company, and shall adopt and perform all its contracts and engagements now binding. Every shareholder other than Mr. John Tasker will be entitled to one new share, credited with £8 as paid up in respect of each £10 share in the old company, and the said Mr. J. Tasker, in respect of each of 3,077 shares, with £8 paid up, shall have allotted to him, or his nominees, one share in the new company, credited with £8 paid up; and he undertakes to make no claim in respect of 2,000 fully paid shares held by him.

**Plymouth and District Pulsion Telephone.**—The statutory return of this company, made up to the 25th ult., was filed 29th ult. The nominal capital is £4,600, in £1 shares. 4,150 shares are taken up, upon 3,100 of which 1s. per share has been called, and upon £1,050, 3s. per share. The calls paid amount to £3,257 10s.

**Woking Electric Supply Company, Limited.**—The annual return of this company, made up to the 19th ult., was filed 24th ult. The nominal capital is £20,000 in £5 shares. 2,067 shares are taken up, 2,000 of which are considered fully paid. Upon 60 shares 5s. per share has been called, and upon seven shares £1 5s. has been called, the calls paid amounting to £23 15s.

**Nonpariel Electric Syndicate, Limited.**—An agreement of 21st ult. (filed 27th ult.) with J. Tarbottom Armstrong, of 8, Suffolk Lane, and J. Mason, of 28, Cardigan Road, Bow (the vendors), provides for the purchase by the company of the letters patent No. 1,757, dated 12th October, 1880, relating to an improved automatic coin-freed apparatus for imparting electric shocks, together with the machines and appliances belonging to the vendors. The consideration is £4,000, half in cash and half in fully-paid shares.

## CITY NOTES, REPORTS, MEETINGS, &amp;c.

**Fowler-Waring Cables.**—Meetings of electrical companies have been prolific during the past few days. Fowler-Waring Cables shareholders dropped in to their annual meeting to ascertain the date of probable dividends. The chairman met them with statements of delays (not specified), which were now overcome. A good factory had been secured, an able manager was running it, and the directors expected that from that day there would be nothing but plain sailing. It is a remarkable fact that the position of a company looks brighter and sounder on the day of the annual meeting than at any other subsequent or previous period. Shareholders were invited to view samples of work at the London office, and the machinery at the works. If this were done, it was said, they would recognise the sound basis on which the company rested. It is to be hoped, and we believe, that there is a sounder foundation than samples and machines. In the course of the meeting it was remarked that the board of directors, which is certainly a large one, ought to be reduced. It is said that one member, Colonel North, is so impressed with the capabilities of his colleagues that he has not deemed it necessary to put in an appearance at any single board meeting this year.

**The Electric Construction Corporation.**—This corporation held its first annual meeting on Monday. The chairman (Sir H. Mance) remarked that the company possessed patents of undoubted value, which, although undeveloped, would, in the hands of subsidiary companies, now formed, prove a solid source of income. Upon paper their transactions looked very flourishing indeed, but he hoped shareholders would support the policy of the directorate in the decision not to apply any profits of the sales of patents to the credit account until the patents had been written off. They were carrying on, at Wolverhampton and Millwall, continuous experiments. A notable one was the extraction of phosphorus by means of electricity. In view of the progress of electric lighting in England, and probable contracts, was decided, in order to secure increased business, to make an issue of £100,000 of debentures bearing six per cent.

**Reuter's Telegram Company as an Advertising Concern.**—Reuter's Telegram Company is taking advantage of that clause of articles of association which enables any commercial undertaking to make money out of business, as widely different as the supply of public electric lighting and the washing of private linen. It is intended to take up an international advertising agency by means of their cables.

**The National Telephone Company; another Magna Charta.**—The National Telephone Company will pay, in a few days, a dividend of 5 per cent., which is the last before the expiry of the patents held by it and its predecessor with peculiar injudiciousness for a good many years. During this period, their bearing towards customers has slowly, if silently, created a host of enemies, whose ill feeling and bitterness may have great influence on future developments of this concern. The company's position is analogous to that of King John, and the charter of liberty for the users of the telephone may be said to date from July of 1891.

**The Gülcher (New) Electric Light and Power Company, Limited.**—The report of this company and balance-sheet to June 30th, 1890—nearly six months after date—are to hand. An important feature mentioned in the report is that the 10 per cent. debentures, of which class only £400 at present remains unredeemed, has been paid off. We notice that a detailed profit and loss account will be submitted to the shareholders at the general meeting. As the balance from this account (£201 17s. 7d.) is given in the balance-sheet, it is difficult to see why so long a period should elapse before the detailed statement is ready. The directors state that the heavy interest payable on the second mortgage debentures has alone prevented the payment of a dividend, and now that these are practically cleared off, we hope that this year's account will prove even much more satisfactory than the last.

**The Fowler-Waring Cables Company, Limited.**

THE first annual report of the Fowler-Waring Cables Company was presented to the shareholders on Friday last. At the time of the statutory meeting they hoped that the buildings and

machinery would be completed in spring or early summer, but there were so many unexpected delays, that only within a recent period has it been possible to execute orders at North Woolwich. The directors regret that in consequence of these delays they are unable to present a favourable balance-sheet, but they are glad to be able to state that the work is now proceeding well, and they look forward with confidence to the future.

A transfer of the work from Leeds has been effected, and a portion of the plant has been taken over, in accordance with the agreements made with Messrs. John Fowler and Company (Leeds), Limited.

The following is the general manager's report:—Since assuming the management of the company in the beginning of July, I have been mainly occupied with the organisation and equipment of the factory, which is now on a thoroughly good working basis. Many of the machines, which are of a particularly light construction, were, unfortunately, damaged in transport from America, and the repairs and renewals have been somewhat tedious, and have necessarily involved considerable delay. They are now, however, in operation, they are highly efficient machines, and it is doubtful if their working capacity is rivalled in this country.

In the selection of suitable foremen for the various departments, I have been specially fortunate in securing the services of a number of men of long experience in cable manufacture, and the quality of the work now produced is most favourably commented upon by all who have used or seen our cables. Although the orders completed up to date do not represent a very large sum, they are still significant as opening business in all the important branches of electrical engineering, and in no case is there a failure recorded against our company.

In telephony, we have manufactured a number of important cables for the National Company, and one composed of 50 wires is now being laid in the tunnels of the Metropolitan Railway. In cost and efficiency, I believe we can easily distance all our rivals in telephone cables, and there must be an immense development in the immediate future of underground telephone systems.

In telegraphy, we have had opening orders from several of the leading railway companies, and our prospects with the Post Office Telegraph Department are exceedingly good. We have also fulfilled trial orders for several of the Colonial Telegraph Departments, and our reports from them foreshadow future business.

The branch of electrical engineering which is at present commanding most attention is the transmission of power, and it is satisfactory that only our cables are employed in the new City and South London Subway, which is the first electric railway in this country.

In electric lighting, we have a constantly-increasing business, but it is here we meet with the keenest competition. The use of lead-covered cables will greatly extend when their value becomes more widely known. Rubber covered wires, however, are often specified to the exclusion of all others, and we think it advisable to meet the large demand for these conductors, and my arrangements for the manufacture of these are almost complete. It is our intention to manufacture all classes of electrical conductors, and we are also prepared to contract for carrying out electrical operations of every description.

Every year marks a steady advance in the progress of the electrical industries, and I am confident that we shall have an important share in the developments of the future. Our factory is splendidly situated, and admirably adapted to our requirements.

At the meeting the Chairman (Mr. W. Fowler) said that when he had met the shareholders a year ago he had certainly anticipated that they would make further progress during that period than had proved to be the case; but they had met with unexpected delay, and were consequently not so forward as they had hoped to be. He was glad to tell them, however, that they had now a factory in most excellent order, and would be able to do a large and profitable business in future. They had, too, and had had for some months past, a most excellent manager, who resided in the factory, and was consequently able to exercise a continued supervision. He would like any shareholder who felt any doubt about the company to go down and look over the factory; he thought he would agree that the position was a good one, the machinery excellent, and the work of the most superior quality. As to the quality of the work, an inspection of the samples to be seen at their offices in Queen Street would satisfy anyone that it was of the most excellent character. With regard to the condition of the company's business, the report—combining as it did both the managers' and directors'—stated that so clearly, that it was needless for him to add to it. He would say, however, that as the directors had made no profits for the shareholders (perhaps they ought not to have expected any the first year) they had taken no fees, although they had done a great deal of hard work, and had had a great deal to think about.

The report was seconded and carried *nem. con.*

On the motion to re-appoint the auditors, a shareholder objected to the amount of fees (50 guineas per annum) which they received, and it was finally resolved that though they should be re-appointed, that the directors should confer with them and endeavour to obtain a reduction.

The same shareholder thought that seven directors were too many for so small a company. It would be most invidious for him to single out any individual, but he hoped that the board would themselves consider this matter, and that when next the company was assembled there would be a smaller directorate.

The usual vote of thanks concluded the meeting.

### The Electric Construction Corporation.

THE first ordinary general meeting of this corporation was held at Worcester House last Monday.

The Secretary read the notice convening the meeting, and also the auditors' report.

The Chairman (Sir Henry C. Mance), in going through the accounts, said that the £4,061 on account of apportionment of profit between the vendor and the corporation, which appeared on the credit side of the profit and loss account, represented the amount which, after liberal deductions for depreciation, cost of experiments, &c., the auditors certified as profits belonging to capital, and that, although they had taken over the benefit of the work of the company from September, 1888, they were not allowed to account as revenue any profits made before the date of the incorporation of the company, but they would understand that though they had not these earnings set out as profits, they had them in the increased value of the business. The items works, sales, and expenses spoke for themselves, and he had only one remark to offer—that, in working out the rate of profit, they should deduct a considerable part of the £14,000 charged as head office expenses, for these expenses covered a period of nearly 16 months—not merely 12. In connection with the interest upon temporary loans, it had been necessary to obtain temporary advances from their bankers in order to complete the agreement with the vendors. Part of it might have been charged to capital, but the directors had thought the placing of the affairs of the company upon a sound financial basis was of more importance than the presenting a more favourable balance-sheet. Speaking of the expenses they had been put to for advertising, the chairman said they would easily understand that advertising must always be a serious cost. Considerable expense, too, had been incurred for goods sent to the Edinburgh Exhibition, which was practically another form of advertising, and in pursuance of a policy of being always on the safe side, and of remembering that returned goods were often much depreciated in value, they had written the expense entirely off their books, so that if anything came into the funds from it it would be all profit. When the corporation had taken over the business there had been foreign patents of undoubted but of undeveloped value. The patent fees themselves were a heavy charge, whilst the income was nominal. The directors had realised these foreign patents by handing them over to subsidiary companies and accepting payment in shares. Experiments were constantly being made at their works at Wolverhampton and Millwall, and the chairman anticipated that before very long they would be possessed of a means of obtaining phosphorus by means of electricity. It might be in the minds of some of the shareholders that the aluminium process had been entirely revolutionised by the application of electricity, and he saw no reason why it should not be so with phosphorus. Turning to the balance sheet, he regretted that calls in arrear should form so large an item, but they had been passing through a very difficult and trying time in the City, and many gentlemen had had great difficulty in meeting the calls made upon them. Liabilities to trade accounts included a substantial sum in reserve, which they were not likely to be called upon to use, and the liabilities to capital account were almost paid off, though there were still considerable liabilities for the Bushbury works, and other matters, in course of settlement. Their contract for the equipment of Rathbone Place and Manchester Square stations was now almost complete, though there was a responsibility for the running of the machinery which would not disappear for some time to come. With regard to contingent liabilities for calls made by the subsidiary companies, there was not much likelihood of their becoming actual liabilities, except in case of such a development of the business of these subsidiary companies as would be a matter of congratulation to themselves. Turning to the credit side, the purchase money, £397,300, had been reduced by stock, book debts, &c. This was merely a matter of book-keeping, for the items appeared lower down; but the further reduction of £100,000 for licenses and sales was not a matter of book-keeping, a fact on which they might congratulate themselves. Their capital expenditure since the acquisition of the business had been practically limited to the laying out of the new Bushbury works, the cost of which had been greater than was originally contemplated; but they had felt themselves bound to be liberal in this direction for the sake of the increased facility in turning out work, for while they warmly desired to make profits out of the subsidiary companies, they must look for future dividends to their manufacturing profits, and their business was to put their company into the foremost rank, as they had endeavoured to do. While on this subject, it was not enough to have a reputation for turning out good work—that they had—they must have a reputation for turning it out with despatch. During the past year they had been obliged to refuse orders because they could not guarantee delivery within the time appointed; but now they had a factory at their disposal, which would enable them to meet all the requirements likely to be made in the future, as the shareholders would agree if they would go down and see it for themselves. Looking at the numerous applications made all over the country for provisional orders, and the progress already made by the different supply companies, they could have no doubt for the future of the electric light; but great as was this field, he thought it likely to be eclipsed by the demand made for electricity for other purposes. In America, the motor industry was greater than the lighting industry. In this matter they were not only better, they were cheaper than any of their rivals. If any of the share-

holders should visit their works at Bushbury they would find how thoroughly the directors believed in the future transmission of power by electricity for all the machinery there was worked by power communicated electrically. They had been disappointed in the matter of train lighting, and gentlemen who owned shares in railways were urged to bring pressure to bear upon their directors, but they had been more fortunate with electric traction, for a series of electric tramcars had been established at Birmingham, where they were now working in a very satisfactory manner, and this he hoped was only the first of a long series of installations to be made all over the country. Seeing these installations coming, and having regard to the necessary expenditure on new works, he thought the time had now come to ask for more capital. They proposed to issue the sum of £150,000, in 6 per cent. debentures. They had postponed this as long as possible, but they thought now they would be neglecting the interests of their shareholders if they did not make the issue at the very latest early next year. They hoped these debentures would be mainly taken up by the shareholders, while as for the directors they were quite willing to take up more than their share. There would, however, be a public issue in order to get a quotation on the Stock Exchange.

Some shareholders having spoken criticising the action of the directors in selling so large a part of their business to subsidiary companies, as turning into a company promoting what should be a manufacturing concern, and one of them having asked whether this had anything to do with the retirement of Sir Douglas Fox,

Mr. J. Spencer Balfour stated in reply that there was no reason whatever for the retirement of Sir Douglas Fox except the one he himself assigned, namely, that he had not time to attend to the affairs of the company. As to the policy of the board in selling their business to subsidiary companies, it was the wisest course to adopt, because it enabled them to give their attention to manufacturing, which would otherwise be neglected. As to the rate of interest—6 per cent.—which was proposed to be paid upon debentures, this was the usual rate, but the debentures could easily be issued at 5 per cent. if the shareholders in the corporation would take them at that rate.

The adoption of the report having been moved, seconded and carried, the question of the reappointment of the retiring directors came up for discussion. Sir Daniel Cooper, with Messrs. Balfour, Courtenay and Dibley were reappointed, and Mr. Mander proposed that Mr. Thomas Parker, the managing director of the company, take the place of Sir Douglas Fox, resigned. This was opposed by Sir Daniel Cooper and some shareholders on the ground that a seat at the board would be incompatible with his present position as servant of the corporation, and the motion was finally withdrawn.

The auditors were then re-elected, and a vote of thanks to the chairman and board concluded the meeting.

### Reuter's Telegram Company, Limited.

ON Saturday last, at 12, a special general meeting of the company was held at their offices in Old Jewry. The secretary read the notice convening the meeting, and two resolutions, the first, that the company's capital be increased to £100,000; and the second, altering the provisions of the memorandum of association and giving the company power to carry on the business of advertisement contractors and agents.

The Chairman (Sir J. C. D. Hay) remarked that the two resolutions were interdependent upon one another, and that unless both were carried the other one would be inoperative. Proceeding, he said that: Before moving the adoption of the resolutions, he would explain the objects in view in asking an extension of the powers of the company and an increase of capital. They must not suppose that the present capital was insufficient for the existing business. True, they had to incur considerable expense in keeping abreast with the growing demands for telegraphic intelligence, but at present their capital was adequate, so far as it was necessary to provide agents and correspondents with funds; and though it might be found advisable in the interests of their subscribers to supplement existing services with special accounts of remarkable events, trials, fires, &c., on a larger scale than had been hitherto considered necessary, yet these would be the subject of further consideration in conjunction with the newspapers themselves, and would, no doubt, be met by the contributions which would recoup the outlay. The primary object of the proposed alteration in their memorandum of association, and the increase of their capital, was to enable them to undertake the business of collecting advertisements for the newspapers, who were their supporters. Their organisation was particularly adapted for this class of business, and the idea had been long entertained by their managing director, who had not failed to notice the great expansion of advertising of late years. The law had until recently regarded a memorandum of association as unalterable; but during last session an Act was passed empowering companies, under the sanction of the High Court, to enlarge the sphere of their operations, of which power they proposed to avail themselves. It was obvious that with agencies in all the capitals of the world who were brought into direct communication with the newspapers, that the company had exceptional means of establishing an international advertising business on a large scale, with immense advantage to their subscribers. Some apprehension had been expressed in certain quarters that the working of the advertisement business might

prove detrimental to the telegraphic services, inasmuch as the latter had to deal with financial affairs, and many things that advertisers might influence; but he would point to their reputation, and ask if it were likely that the directors would commit the suicidal folly of allowing any advertiser to influence the impartiality which had characterised their service since its creation. As a safeguard, however, it was proposed to keep the telegrams strictly apart from the advertising branch, which would be managed by a separate staff in separate offices. They were sanguine that the new business would be found a good source of revenue, but shareholders must not look for increased dividends at the commencement. The organisation of an international business took time, and could only be accomplished after much negotiation; but they had taken preliminary steps abroad in conjunction with the largest advertising agency on the continent, and as soon as the shareholders' consent was obtained, and the sanction of the High Court obtained, they would be ready to start the new machinery. In addition to advertisement business, they believed it might be found profitable to undertake telephonic and other services, and to extend their business in many directions, now barred by their restricted memorandum of association.

The Chairman then put the resolutions, which were seconded by Baron de Reuter, and carried *nem. con.* Another meeting will be held, in accordance with the Act, on the 23rd, to confirm them.

The Ward Electrical Car Company, Limited.

The first annual general meeting of this company took place at the depot, 12, Dacre Street, Westminster, on Wednesday, the 3rd December, 1890, Mr. E. R. Cummins in the chair.

The Chairman reported that the details of the contract for the construction of the first line of omnibuses, and for the charging station, had now been finally settled with the Electric Construction Corporation, Limited, and that the work will be at once proceeded with; also that the Board intended, as soon as this line is running, to form a sub-company for London, to take over the station and omnibuses, and to work a large line of vehicles; that the various authorities concerned view with great interest the pending introduction of electrical carriages on the streets of London; and that it is intended to form sub-companies for other places in the U.K. and abroad.

The Managing Director then reported having just received an order for an electrical van for trade purposes from a firm who intend to largely introduce them, and that an important tramway company had practically concluded to place a contract with this company.

The Gülcher (New) Electric Light and Power Company, Limited.

The directors in their report state that they have pleasure in presenting to the shareholders the balance-sheet for the 12 months ending 30th June, 1890.

It will be observed that the preference capital of the company, which on the 30th June, 1889, consisted of 12,277 preference shares, having £12,241 1s. 4d. paid up, consisted on the 30th June, 1890, 50,000 preference shares, having £30,797 8s. paid up.

It will also be seen that the £10 per cent. 2nd debentures, which, on the 30th June, 1889, amounted to £8,862 10s., and which, at the date of the last report, had increased to £16,000, were on the 30th June, 1890, reduced to £400.

This satisfactory alteration of the capital account is mainly due to the response made by a limited number of shareholders to the prospectus issued on the 1st January last, inviting subscriptions for the then unissued preference shares.

The central stations for the public lighting of Wellington, New Zealand, upon which, on the 30th June, 1889, the company had expended £9,598 18s. 8d. were shortly afterwards completed. On the 30th June, 1890, this important installation stood as a debtor in the company's books for £13,486 13s. 3d., since which time the amount has not been increased.

The directors, in their last report, pointed out to the shareholders that the commercial success of this undertaking would depend entirely upon the provision of further capital for private lighting. They concluded, however, after careful consideration, not to lock up so large a portion of the newly-subscribed capital as would be necessary to enable the company exclusively to provide for this private lighting. A well-supported syndicate has accordingly been formed, which will not only provide for the private supply of the town but will ultimately take over this company's business in New Zealand, together with the benefit of the contract for public lighting, entered into between this company and the Mayor and Corporation of Wellington.

The particulars of the contract between the New Zealand Electrical Syndicate and this company, and of other contracts undertaken and carried out during the past year, will be supplied at the general meeting, when a detailed profit and loss account will also be submitted to the shareholders.

In the autumn of last year this company contributed towards the registration of "The South-Western District and Thames Valley Electricity Supply Company, Limited," from which the directors have reason to anticipate good results.

The gross manufacturing profits for the year ending 30th June, 1890, amounted to £3,097 2s. 4d., which, compared with the manu-

facturing loss of £1,417 6s. 6d. in the preceding year, must be regarded with satisfaction.

The heavy interest payable on the second mortgage debentures (nearly all of which, however, have been now paid off), has alone prevented the declaration of a dividend. Since the last general meeting Mr. Binswanger has resigned his seat at the board. The directors, under the powers conferred on them by the articles of association, recently elected Mr. C. S. B. Hilton, a large shareholder, to assist in the direction of the company. Mr. De Castro and Mr. Hilton retire from the board, but, being eligible, offer themselves for re-election.

Mr. Russell Day, the auditor appointed at the last general meeting, also retires, but offers himself for re-election.

THE BALANCE SHEET, JUNE 30TH, 1890.

## THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.

(Continued from page 682.)

## TIME CONSTANTS OF ELECTRO-MAGNETS.

I may here refer to some determinations made by M. Vaschy,\* respecting the co-efficients of self-induction of the electromagnets of a number of pieces of telegraphic apparatus. Of these I must only quote one result, which is very significant; it relates to the electro-magnet of a Morse receiver of the pattern habitually used on the French telegraph lines.

	L, in quadrants.
Bobbins, separately, without iron cores	0.233 and 0.265
Bobbins, separately, with iron cores ...	1.65 and 1.71
Bobbins, with cores joined by yoke, coils in series ...	6.37
Bobbins, with armature resting on poles ...	10.68

It is interesting to note how the perfecting of the magnetic circuit increases the self-induction.

Thanks to the kindness of Mr. Preece, I have been furnished with some most valuable information about the coefficients of self-induction, and the resistance of the standard pattern of relays, and other instruments which are used in the British postal telegraph service, from which data one is able to say exactly what the time constants of those instruments will be on a given circuit, and how long in their case the current will take to rise to any given fraction of its final value. Here let me refer to a very capital paper by Mr. Preece in an old number of the "Journal of the Society of Telegraph Engineers," a paper "On Shunts," in which he treats this question, not as perfectly as it could now be treated with the fuller knowledge we have in 1890, about the coefficients of self-induction, but in a very useful and practical way. He showed most completely that the more perfect the magnetic circuit is—though, of course, you are getting more magnetism from your current—the more is that current retarded. Mr. Preece's mode of experiment was extremely simple; he observed the throw of the galvanometer, when the circuit which contained the battery and the electromagnet was opened by a key which at the same moment connected the electro-magnet wires to the galvanometer. The throw of the galvanometer was assumed to represent the extra-current which flowed out. Fig. 56 represents a few of the

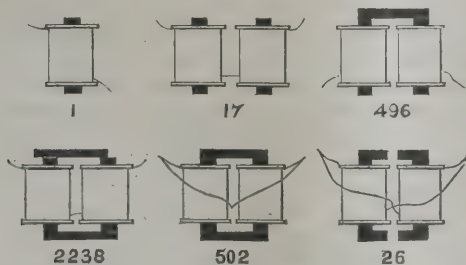

FIG. 56.—ELECTRO-MAGNETS OF RELAY, AND THEIR EFFECTS.

results of Mr. Preece's paper. Take from an ordinary relay a coil with its iron core, half the electro-magnet, so to speak, without any yoke or armature. Connect it up as described, and observe the throw given to the galvanometer. The amount of throw obtained from the single coil was taken as unity, and all others were compared with it. If you join up two such coils as they are usually joined, in series, but without any iron yoke across the cores, the throw was 17. Putting the iron yoke across the cores, to constitute a horseshoe form, 496 was the throw; that is to say, the tendency of this electro-magnet to retard the current was 496 times as great as that of the simple coil. But when an armature was put over the top the effect went up to 2,238. By the mere device of putting the coils in parallel, instead of in series, the 2,238 came down to 502, a little less than the quarter value which would have been expected. Lastly, when the armature and yoke were both of them split in the middle, as is done in fact in all the standard patterns of the British Postal Telegraph relays, the throw of the galvanometer was brought down from 502 to 26. Relays so constructed will work excessively rapidly. Mr. Preece states that with the old pattern of relay having so much self-induction as to give a galvanometer throw of 1,688, the speed of signalling was only from 50 to 60 words per minute; whereas, with the standard relays constructed on the new plan, the speed of signalling is from 400 to 450 words per minute. It is a very interesting and beautiful result to arrive at from the experimental study of these magnetic circuits.

## SHORT CORES versus LONG CORES.

In considering the forms that are best for rapid action, it ought to be mentioned that the effects of hysteresis in retarding changes in the magnetisation of iron cores are much more noticeable in the case of nearly-closed magnetic circuits than in short pieces. Electro-magnets with iron armatures in contact across their poles will retain, after the current has been cut off, a very large part of their magnetism, even if the cores be of the softest of iron. But so soon as the armature is wrenched off the magnetism disappears. An air-gap in a magnetic circuit always tends to hasten demagnetising. A magnetic circuit composed of a long air-path and a short iron-path demagnetises itself much more rapidly than one composed of a short air-path and a long iron-path. In long pieces of iron the mutual action of the various parts tends to keep in them any magnetisation that they may possess; hence they are less readily demagnetised. In short pieces, where these mutual actions are feeble or almost absent, the magnetisation is less stable, and disappears almost instantly on the cessation of the magnetising force. Short bits and small spheres of iron have no "magnetic memory." Hence the cause of the commonly received opinion amongst telegraph engineers that for rapid work electro-magnets must have short cores. As we have seen, the only reason for employing long cores is to afford the requisite length for winding the wire which is necessary for carrying the needful circulation of current to force the magnetism across the air-gaps. If, for the sake of rapidity of action, length has to be sacrificed, then the coils must be heaped up more thickly on the short cores. The electro-magnets in American patterns of telegraphic apparatus usually have shorter cores, and a relatively greater thickness of winding upon them, than those of European patterns.

## LECTURE IV.—DELIVERED FEBRUARY 10TH, 1890.

## ELECTRO-MAGNETIC MECHANISM.

THE task before me to-night comprises the following matters:—First, to speak of that particular variety of the electro-magnet in which the iron core, instead of being attached to the coils, is movable, and is attracted into them. Secondly, to speak of the modes of equalising the pull of electro-magnets of various sorts over their range of action. Thirdly, to describe sundry mechanisms which depend on electro-magnets. Lastly, to discuss the modes of prevention or diminution of the sparking which is so almost invariably found to accompany the break of circuit when one is using an electro-magnet.

## THE COIL-AND-PLUNGER.

First, then, let me deal with the apparatus wherein an iron core is attracted into a tubular coil or solenoid, an apparatus which, for the sake of brevity, I take the liberty of naming as the *coil-and-plunger*. Now, from quite early times, from 1822 at any rate, it was known that a coil would attract a piece of iron into it, and that this action resembled somewhat the action of a piston going into a cylinder—resembled it, I mean to say, in possessing an extended range of action. The use of such a device as the coil-and-plunger was even patented in this country in 1846 under the name of "a new electro-magnet." Electro-magnetic engines, or motors, were made on this plan by Page, and afterwards by others, and it became generally known as a distinct device. But even now, if you inquire into the literature of the text-books to know what are the peculiar properties of the coil-and-plunger arrangement, you will find that the books give you next to no information. They are content to deal with the thing in very general terms by saying: here is a sort of sucking magnet; the core is attracted in. Some books go so far as to tell you that the pull is greatest when the core is about half way in, a statement which is true in one particular case, but false in a great many others. Another book tells you that the pull is greatest at a point one centimetre below the centre of the coil, for plungers of all different lengths—which is quite untrue. Another book tells you that a wide coil pulls less powerfully than a narrow one, a statement which is true for some cases and not for others. The books also give you some approximate rules, which, however, are very little to the point. The reason why this ought to receive much careful consideration is because in this mechanism of coil-and-plunger we have a real means not only of equalising, but also of vastly extending the range of the pull of the electro-magnet. Let us take a very simple example for the sake of contrasting the range of action of the ordinary electro-magnet with the range of action of the coil-and-plunger.

Here are some numbers which are given in a paper with which I have long been familiar, a paper read by the late Mr. Robert Hunt in 1856 before the Institution of Civil Engineers, and discussed, with that eminent engineer, Robert Stephenson, in the chair. Mr. Hunt described the various types of motors, and spoke of this question of the range of action. He recounted some experiments of his own in which the following was the range of action. There was a horse-shoe electro-magnet which at a distance zero—that is, when its armature was in contact—pulled with a pull of 220 lbs.; when the distance was made only  $\frac{1}{1000}$ th of an inch (4 mils), the pull fell to 90; and when the distance was increased to 20 mils ( $\frac{1}{50}$ th of an inch), the pull fell to only 36 lbs. The difference from 220 to 36 was within a range of  $\frac{1}{50}$ th of an inch. He contrasts this with the results given by another mechanism, not quite the simple coil

and plunger, but a variety of electro-magnet brought out about the year 1845 by a Dane living in Liverpool named Hjörth, wherein a sort of hollow truncated cone of iron (fig. 57), with coils wound upon it—a hollow electro-magnet, in fact—was caused to act on another electro-magnet, one being caused to plunge into the other. Now we have no information what the pull was at

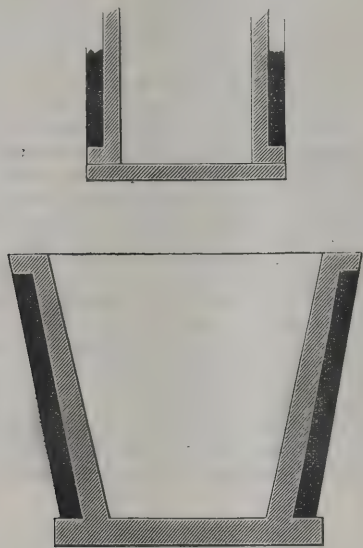

FIG. 57.—HJÖRTH'S ELECTRO-MAGNETIC MECHANISM.

distance zero with this curious arrangement of Hjörth's, but at a distance of 1 inch the pull (with a very much larger apparatus than Hunt's) was 160 lbs., the pull at 3 inches was 88 lbs., at 5 inches 72 lbs. Here, then, we have a range of action going not over  $\frac{1}{10}$ th of an inch, but over 5 inches, and falling not from 220 to 36, but from 160 to 72, obviously a much more equable kind of range. At the Institution of Civil Engineers on that occasion, a number of the most celebrated men, Joule, Cowper, Sir William Thomson, Mr. Justice Grove, and Professor Tyndall discussed these matters—discussed them up and down—from the point of view of range of action, and from the point of view of the fact that there was no means of working them at that time except by the consumption of zinc in a primary battery; and they all came to the conclusion that electric motors would never pay. Robert Stephenson summed up the debate at the end in the following words:—"In closing the discussion," he remarked, "there could be no doubt from what had been said that the application of voltaic electricity, in whatever shape it might be developed, was entirely out of the question commercially speaking. Without, however, considering the subject in that point of view, the mechanical applications seemed to involve almost insuperable difficulties. The power exhibited by electro-magnetism, though very great, extended through so small a space as to be practically useless. A powerful magnet might be compared, for the sake of illustration, to a steam engine with an enormous piston, but with an exceedingly short stroke; such an arrangement was well known to be very undesirable."

Well, from the discussion in 1856—when this question of the length of range was so distinctly set forth—down to the present, there have been a large number of attempts to ascertain exactly how to design a long range electro-magnet, and those who have succeeded have, as a general rule, not been the theorists; rather they have been men compelled by force of circumstances to arrive at their result by some kind of—shall we call it—"designing eye," by having a sort of intuitive perception of what was wanted, and going about it in some rough and ready way of their own. Indeed, I am afraid had they tried to get much light from calculations based on orthodox notions respecting the surface distribution of magnetism, and all that kind of thing, they would not have been much helped. There is our old friend, the law of inverse squares, which would of course turn up the first thing, and they would be told that it would be impossible to have a magnet that pulled equally through any range, because the pull was certain to vary inversely according to the square of the distance. I notice that, in a report of my second lecture in one of the London journals, I am announced to have said that the law of inverse squares did not apply to electric forces. I beg to remark that I have said no such thing. It is well to be precise as to what one does say. There has been a lively discussion going on quite lately whether sound varies as the square of the distance—or rather, whether the intensity of it does—and the people who dispute on both sides of the case do not seem to know what the law of inverse squares means. I have also seen the statement made last week in the columns of the *Times* by one who is supposed to be an eminent authority on eyesight, that the intensity of the colour of a scarlet geranium varies inversely with the square of the distance from which you see it. More utter nonsense was never written. The fact is, the law of inverse squares, which is a perfectly true mathematical law, is true not only for electricity but for light, for sound, and for everything else, provided it is applied to the one case to which a law of inverse squares is applic-

able. That law is a law expressing the way in which action at a distance falls off when the thing from which the action is proceeding is so small compared with the distance in question that it may be regarded as a point. The law of inverse squares is the law universal of action proceeding from a point. The music of an orchestra at 10 feet distance is not four times as loud as at 20 feet distance; for the size of an orchestra cannot be regarded as a mere point in comparison with these distances. If you can conceive of an object giving out a sound, and the object being so small in relation to the distance at which you are away from it, that it is a point, the law of inverse squares is all right for that, not for the intensity of your hearing, but for the intensity of that to which your sensation is directed. In no case, however, are sensations absolutely proportional to their causes. When the magnetic action proceeds from something so small that it may be regarded as a point compared with the distance, then the law of inverse squares is necessarily and mathematically true.

You may remember that I produced an apparatus (fig. 27) which I said was the only apparatus hitherto devised which did directly prove experimentally the law of inverse squares for the case of a magnetic pole. There was in it a pole, virtually a point at a considerable distance from a small magnetic needle, which was also virtually a point.

The law of inverse squares is true; but it is not what one works with when one deals with electro-magnets having ends of a visible size, acting on armatures themselves of visible sizes, and quite close to them. If you take a case which never occurs in practice, an armature of hard steel, permanently magnetised, so far away from an electro-magnet (or rather from one pole only) that the distance between the one pole and the armature on which you are acting is so very great compared with each of them, that each of them may be regarded by comparison as a point, then the law of inverse squares may be rightly applied, but not unless.

Now we want to arrive at a true law. We want to know exactly what the law of action of the coil and plunger is. It is not a very difficult thing to work out, provided you get hold of the right ideas. We must begin with a simple case, that of a short coil consisting of but one turn acting on a single point pole. From this we may proceed to consider the effect on a point pole of a long tube of coil. Then we may go on to a more complex case of the tube coil acting on a very long iron core; and, last of all, from the very long iron core we may pass to the case of a short core.

You all know how a long tube of coil such as this will act on an iron core. Let us make an experiment with it. I turn on the current so that it circulates around the coil along the tube, and when I hold in front of the aperture of the tube this rod of soft iron, it is sucked into the coil. When I pull it out a little way it runs back, as with a spring. The current happens to be a strong one—about 25 amperes; there are about 700 turns of wire on the coil. The rod is about 1 inch in diameter and 20 inches long. So great is the pull that I cannot pull it entirely out. The pull was very small when the rod was outside, but as soon as it gets in it is pulled actively, runs in, and settles down with the ends equally protruding. The tubular coil I have been using is about 14 inches long; but now let us consider a shorter coil. Here is one here only half-an-inch from one end to the other, but I have one somewhere still shorter, so short that the length, parallel to the axis, is very small compared with the diameter of the aperture within. The wire on it consists of but one single turn. Taking such a coil, treating it as only one single ring, with the current going once round, in what way does it act on a magnet that is placed on the axis? First of all, take the case of a very long, permanently magnetised steel magnet, so long, indeed, that any action on the

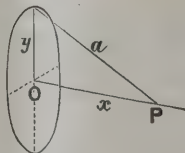

FIG. 58.—ACTION OF SINGLE COIL ON POINT-POLE ON AXIS.

more distant pole is so feeble that it may be disregarded altogether, and only one pole, say the north pole, is near the coil. In what way will that single turn of coil act on that single pole? This is the rule, that the pull does not vary inversely as the square of the distance, nor as any power at all of the distance measured straight along the axis, but inversely as the cube of the slant distance. Let the point *o* in fig. 58 represent the centre of the ring, its radius being *y*. The line, *o p*, is the axis of the ring, and the distance from *o* to *p* we will call *x*. The slant distance from *p* to the ring we call *a*. Then the pull on the axis towards the centre of this coil varies inversely as the cube of *a*. That law can be plotted out in a curve for the sake of observing the variations of pull at various points along the axis. Allow me to draw your attention to fig. 59, which represents a section or edge view of the coil. At various distances right and left of the coil are plotted out vertically the corresponding force, the calculations being made for a current of 10 amperes, circulating once around a ring of 1 centimetre radius. The force with which such a current acts on a magnetic pole of unit strength placed at the central point is 6.28 dynes. If the pole is moved away down the axis, the pull is diminished; at a distance away equal in length to the

radius it has fallen to 2.22 dynes. At a distance equal to twice the radius, or one diameter, it is only 0.56 dynes, less than one-tenth of what it was at the centre. At 2 diameters it has fallen

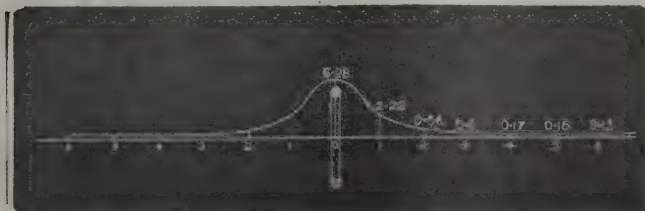

FIG. 59.—ACTION ALONG AXIS OF SINGLE COIL.

to 0.17 dyne, or less than 3 per cent.; and the force at 3 diameters is only about 2 per cent. of that at the centre.

(To be continued.)

18589. "Improvements in electric railway signals." W. H. WADDELL. Dated November 18. (Complete.)

18625. "Improvements in and relating to apparatus for use in electric welding, forging, and other metal-working operations." H. H. LAKE. (Communicated by H. Lemp, United States.) Dated November 18. (Complete.)

18631. "Improvements relating to the welding of metals by electricity." H. H. LAKE. (Communicated by E. Thomson, United States.) Dated November 18. (Complete.)

18638. "Improvements in electricity meters." E. HARTMANN and W. BRAUN. Dated November 18. (Complete.)

18660. "An improved terminal for electric lampholders." A. J. MCGEOCH. Dated November 18.

18776. "Electric telegraphic communication between termini, intermediate stations, &c., and railway trams or vehicles in motion." A. T. J. CUTMORE, and F. H. BOINTON. Dated November 20.

18890. "Improvements in automatic telephone connectors." J. Y. JOHNSON. (Communicated by the Automatic Electric Exchange Company, United States.) Dated November 21.

18896. "Improvements in the process and apparatus for manufacturing copper tubes, sheets, strips, and wires by electrolysis." A. S. ELMORE. Dated November 21. (Complete.)

18904. "Improvements in magneto-electric telephonic apparatus." H. T. O. FRASER. Dated November 21.

18910. "Improved apparatus for stopping machinery by electricity." C. F. JOSZ. Dated November 21.

18913. "An improved electrical switch." E. L. JOSEPH. Dated November 21.

18969. "An improved apparatus for measuring the resistance and insulation of electric conductors." W. A. PRICE and W. E. GRAY. Dated November 22.

18993. "Improvements in and relating to electric clocks." N. PROKHOROFF and N. FAHLBERG. Dated November 22. (Complete.)

ducting portions, a socket and a spring, lying against and insulated from the former by means of ebonite or the like. 4 claims.

15963. "Improvements in the manufacture of electrodes or plates for electrical batteries." Dr. PAUL SCHOOP. Dated October 10. 6d. A compound soluble lead salt is decomposed by an electric current, its constituent parts being deposited upon suitably-shaped conducting plates or supports. Such a compound salt may be prepared by mixing sulpho-glycerine acid or naphthalin-sulpho acid, or both, with sulphuric acid, and adding thereto an oxide or carbonate of lead and one or more of the alkalies, potash, soda, or ammonia, until the acids are neutralised or saturated. 7 claims.

17521. "Improvements in the distribution and regulation of electric currents." W. CLARK. (A communication from abroad by S. Schuckert & Co., of Nürnberg.) Dated November 4. 11d. Consists:—1. In a system of distribution designed for a uniform tension of consumption and receiving electric energy from two or more current supply circuits (a) to regulate tensions at the terminals of all the supply leads with variable consumption of current, and (b) to allow of unequal falls of tension in the several supply leads with a maximum consumption of current. 2. At places where variation in the intensity of the light is required, to allow of the alteration of the tension of the lamps according to the brightness desired, both being effected without the usual resistances which consume uselessly a portion of the electrical energy, and convert the same into heat. 9 claims.

18821. "Improvements in electric baths, or apparatus for applying electricity for medical or other similar purposes." Dr. GUSTAV GAERTNER. Dated November 23. 8d. The inventor divides the bath into two perfectly separate compartments or cells by means of a partition made in two parts. The lower part of this partition is permanently united to the sides and to the bottom of the bath, but the upper part is capable of being removed, or of sliding upwards and downwards in guides, so as to be capable of joining the lower part, and forming with the latter a partition, making a tight joint with the sides and bottom of the bath. Both the upper and the lower divisions of this partition are cut away so as to form an opening between them, the edges of which are provided with India-rubber cushions or pads. Suitable electrodes or metal plates are provided around the interior of the bath at the sides, and those in one compartment are connected with the positive pole, and those in the other compartment with the negative pole of the electric generator or source of electricity. Inside these electrodes or plates a wood lining may be provided. 2 claims.

18939. "Improvements in and connected with railway and tramway vehicles and with their propulsion by means of electricity." H. P. HOLT. Dated November 26. 8d. According to these improvements the body of each vehicle is carried on two bogies, one at each end of the vehicle; but instead of the bogies being entirely below the under-framing, as in ordinary cases, it is arranged that the ends only of the vehicles shall rest upon and be carried by less than one-half of each bogie. 6 claims.

## 1890.

1037. "Improvements in mechanical telephones." R. C. M. BOWLES. Dated January 21. 6d. Consists in suspending or holding the telephone upon the line wire without other support than the wire itself, and then providing means for holding the diaphragm of the telephone under a tension equal to, or proportionate to, that line wire, and it further consists in providing means for adjusting the tension of the diaphragm. 4 claims.

2986. "Improvements in electric lamp sockets and devices attached thereto for regulating the light." W. F. WOLLIN and E. H. WEBERLINE. Dated February 25. 8d. The object of this invention is to provide means for controlling the intensity of the light of an incandescent electric lamp, so that it may be of any degree desired, as is the case with the flame of an ordinary gas burner. 7 claims.

3455. "Improvements in and relating to electric secondary batteries or accumulators." H. H. LAKE. (Communicated from abroad by T. Ewing, of New York.) Dated March 4. 8d. Relates first to a new construction of storage cell, and consists in the combination of the electrodes with the supporting bridge pieces of non-conducting material, with the interposed supporting and spacing bars of like material, and with the bolts or other means of clamping the various parts into a united body; and second, in a new method of preparing active material for use in storage cells, and preferably in cells of the form set forth. 8 claims.

3787. "Improvements in electric railways." H. W. LIBBEY. Dated March 10. 8d. Consists in the peculiar construction of the track and its supports, the construction of the car and the manner of mounting the same, and also in the construction of the switch and the means of shifting a car from an upper to a lower track, or vice versa. 10 claims.

4407. "Improvements in electric railways." J. B. MCGREW. Dated March 21. 8d. Relates to underground conduit electric railways. 7 claims.

## ABSTRACTS OF PUBLISHED SPECIFICATIONS 1889.

11941. "Improvements in switchboards for telephone exchange." MIX and GENEST and W. OESTERREICH, Germany. Dated July 27. 8d. Each switch-hole consists merely of two con-

5344. "Improvements in apparatus for measuring the strength and electromotive force of electric currents." H. H. LAKE. (Communicated from abroad by M. M. Garver, of America.) Dated April 8. 8d. Consists in apparatus for measuring the strength and electromotive force of currents of electricity. In accordance with the special construction adopted, the instrument may be arranged either as an ammeter or device for measuring the strength of a current in amperes, or as a voltmeter for measuring the electromotive force of a current in volts. 10 claims.

5782. "An electric lamp for water closets." A. HIORTH. Dated April 16. 6d. The object of this invention is to provide a means for throwing electric light on the seat of water closets by raising the lid, thereby allowing the user to ascertain whether the seat is clean and the closet generally in proper order. 1 claim.

## CORRESPONDENCE.

### Telegraph Statistics.

The statistical notice in your No. of November 28th, "Use of the Telegraph," is wrong in all figures except in those concerning Great Britain. The correct figures, showing the number of telegrams for every 100 inhabitants (1888) are as follows: Great Britain, 140; France, 80; Germany, 42; Italy, 30; Austria, 22; Hungary, 19; Russia, 9.

The respective figures for 1889, if you care to know, are, according to the reports made by the Telegraph Administrations to the International Telegraph Bureau at Berne are: Great Britain, 163; France, 88; Germany, 45; Italy, 26; Austria, 20; Hungary, 19; Russia, 9. The rhapsodic correspondent of *La Lumière Electrique* must tune down his dithyrambic; he may see from this that his country's civilisation, its industrial progress and intelligence, are just half way to those of Great Britain, and not so very close as he deems fit to infer from incorrect figures.

F. Hennicke,  
Leipzigerstr., 15, G.P.O.

Berlin, W., December 6th, 1890.

### Count Mattei's Coloured Electricities.

My attention has been called to your notice in the November 21st number of your Journal of my published analysis of Count Mattei's so-called "Electricities." You very properly take exception to the inaccurate statements purporting to show they are not electrical. Permit me to explain. I did not anywhere publish the report. Mistakes have occurred in the publication. The words "electrical" (except when quoted as the name of the preparations) should in every case have been printed "magnetic." The absence of electrical properties was shown by the use of the gold leaf electroscope, and by pith-balls. Unfortunately this was omitted in the report as published.

As an old pupil of the late Prof. Guthrie, whose certificate I gained at the Royal School of Mines, I am not likely to confuse electricity with magnetism, or to be anxious, as your last words suggest, to bolster up anything in the way of quackery.

While pointing out such an inaccuracy of nomenclature, it would have done even greater service to science had you further pointed out the utter absurdity of pretending to thus bottle up either electricity or magnetism in liquids for curative purposes. Your Journal is so widely quoted that an authoritative statement from you would do great good in such a matter.

To the scientific mind it may seem even puerile to attempt to show scientifically that such claims are untrue, but, unhappily, it is necessary to do so for the benefit of the general public. Who else would believe it for want of any attempt at disproof.

Alf. W. Stokes.

[We are very pleased to insert this letter, and we hope that our correspondent's disclaimer will meet with general publicity.—EDS. ELEC. REV.]

### Electric Light on Shipboard.

In his interesting letter on the above subject in your last issue, Mr. Rankin Kennedy says:—"The lead-covered wire, without a continuous insulation of vulcanised rubber, is a failure on board ship."

As this statement is not borne out by facts—at all events so far as my own experience is concerned in the lighting of ships of war—it seems to me well that it should be questioned.

The English Admiralty have now for some years employed for a large number of their ships lead-covered cable, with insulation composed of yarn impregnated with bitumen, and as they still continue to specify this combination, it is presumable that they find it to be satisfactory in practice.

Messrs. Sir W. G. Armstrong, Mitchell & Co., of Elswick, have also employed similarly insulated and protected wire and cable throughout a number of war vessels, and I am able to state that with due care in jointing, and in seeing that the cable was both properly handled during the process of fixing, and well made in the first instance, the results have been good.

With insulation of this class it is, of course, highly necessary that the sheathing be made perfectly watertight at all joints; but this is effected by lapping the insulated joint with sheet lead, or covering the joint with a lead sleeve and soldering the whole all round.

Mr. Kennedy's unsatisfactory experience may have been due to this operation having been imperfectly performed, or possibly in the cases on which he bases his opinion the cables may have been injured in erection, or fixed without protection in places where they were liable to violent mechanical wear and tear sufficient to perforate the lead covering. For such localities lead-sheathed cable, however insulated, is obviously unsuitable unless protected with an additional covering of wood or sheet iron.

Provided the joints are made thoroughly watertight, and the lead is maintained intact, the only places where moisture can find its way into the insulation is at the extremities of the wires. There is, however, no great difficulty in properly constructed fittings, suitably placed, in arranging that such ends are kept dry, and where necessary, the wires can be sealed into the fittings, so as to be practically watertight.

On board ship, even more than in the case of land installations, films of condensed moisture are very apt to become deposited on the slate or porcelain bases of switches, cut-outs, &c., and ship engineers are very liable to attribute the resulting defective insulation to bad cables and wires, when these are really in no way to blame.

I have found that in such instances the deficiency of insulation due to this condensed moisture can be removed by electrolysis, it being sufficient to connect one pole of the dynamo to the ship's plating through a safety resistance of one or two lamps, and the other to the lamp circuits, and run the dynamo for a few hours. This has the effect of decomposing the moisture, and the result as regards improved insulation is surprising.

A. A. C. Swinton.

December 8th, 1890.

### The Electro-Deposition of Copper.

With reference to your answers to the eight points selected by me, in which your statements with regard to the Elmore process were seriously incorrect, and in which you requested me to point out your mistakes, I would remark:—1. You accept my correction, but ask me for a statement as to the number of tanks and of amperes required for depositing 20 tons per week. Both these points are given in Dr. Hopkinson's report from which you have quoted, and I would be obliged by your inserting it in full. Yet, as the matter still seems to present some difficulty to your mind, I give the simple calculations.

Taking 1.18 grammes as the weight of copper deposited per ampere-hour, then 600 amperes for 150

hours, in 60 tanks, give  $1.18 \times 600 \times 150 \times 60 = 6,372$  kilos., or slightly more than 6 tons.

Four circuits, therefore, of 600 ampères, or 2,400 ampères in all, will give about 24 tons per week. By a similar calculation, we find that four circuits of 500 ampères each will give slightly over 20 tons per week.

With a current density of 16 ampères per square foot of cathode surface, each tank will require about 32 square feet of cathode, equivalent to a tube of about 10 feet long and 1 foot diameter, while the total cathode surface will amount to 7,680 square feet. We have, therefore, instead of 287,620 ampères, and 15,979 square feet of cathode surface, as given by you, somewhat over 2,000 ampères, and slightly less than 8,000 square feet of cathode surface.

2. I accept your disclaimer, but it is impossible to see the object of your calculations, except to support your contention, which is absolutely opposed to the experience of years, viz., "that to deposit 20 tons per week would involve the use of enormous tanks worked under conditions that would be impossible, except by a heavy outlay for tank space."

My 4th, 5th, 7th and 8th points have not been denied by you.

You state, however, that I claim that the Elmore process enables the size of the tanks to be reduced. This was not my statement.

A tank must be large enough to contain the article which is to be made in it, and this depends entirely upon the requirements of the trade.

I will repeat my statement in slightly different words, in order to make it as clear as possible.

*Cæteris paribus*, the weight of metal which can be deposited in a given time with a given tank plant, varies directly with the current density.

It may be stated with certainty that where coal is cheap, as in England, copper refiners would gladly work with a higher current density than they generally employ, if they could secure a good class of copper.

With regard to the remaining point (6), you endeavour to weaken the importance of the proofs I have brought forward substantiating the other seven points, by referring to them as "side issues."

I am, however, ready to accept your view that the sixth point is the crucial one.

Now, you quoted from M. Fontaine's book the cost of refining in the Norddeutsche Affinerie as £8 per ton, the other two establishments then mentioned working at over £12 per ton. You enquire from the former whether the figure is correct. The answer is just what might be expected.

They state the figure is incorrect.

This strengthens my point.

For as the price for electrically deposited copper in the open market is less than £8 per ton, and it is certain that they are not working at a loss, we may safely assume that it costs them less than £8 per ton.

Why then is Dr. Hopkinson's estimate of £5 per ton so far wrong?

Why, again, should this estimate "be trebled," as contended by you?

It is hardly consistent on your part to suggest now, as you appear to do, that if the price is so low, the Elmore Company will find their profit very small, owing to competition.

You fail, also, to distinguish between the price of the raw material produced in copper refineries, which afterwards has to be worked up into finished articles, and the price of the finished article which is produced by the Elmore method during the process of refining.

In answer to your two queries (a) and (b) on this point I would reply:—

(a) Copper articles produced by the Elmore process can compete most advantageously with copper otherwise prepared, and this in the case of articles for which there is a large demand, and in which the superiority of the article produced at once secures a market.

This point may be determined at once by comparing the market prices for articles such as are particularly adapted for production by the Elmore process with even the exaggerated cost assumed by you.

(b) The economies of the Elmore process are such as to enable the company to sell a superior article at current prices and leave a substantial profit.

W. Stepney Rawson.

December 9th, 1890.

P.S.—Referring, separately, to the letter of Mr. Desmond G. FitzGerald, I have only to say that as regards the work done in the tanks themselves it is immaterial whether they are in series or parallel; but for practical work there is an enormous difference.

The "parallel system" teems with practical difficulties, and I do not think it need be seriously discussed.

As I am not responsible in any way for the article in the New York *Electrical Engineer*, with which, I beg to inform you, I had nothing to do, I will not trouble to follow the several arguments by which Mr. FitzGerald endeavours to justify the employment of a parallel system of electro-depositing. I would simply ask him to be so good as to let your readers know where dynamos can be obtained which will, with a reasonable efficiency, give an output of, say, 100 H.P., with a terminal E.M.F. of 1 volt?

His letter points to the existence of such a machine, although a calculation of its internal resistance appears to place it in the same category as "the bath." Yet as the feasibility of a parallel system depends upon its existence, he, perhaps, can give us the necessary information. It would appear from Mr. FitzGerald's letter that he is responsible for the calculations in the original article, the errors of which I have pointed out, for he says (no doubt inadvertently), "only an outsider would suppose for a moment that our data in relation to a single tank were intended to imply, in case of extended operations, the construction of an enormous reservoir."

[In the above communication, Mr. Stepney Rawson's familiar 8 points again make their appearance. The letter reached us too late to comment upon it at any length, but it confirms the impression we expressed that the "absurdity" which was so very apparent in Mr. Rawson's previous letters, recoils on Mr. Rawson himself. Our correspondent says we have not "denied" some of his points, as he previously said we had not "answered" some others. They were all dealt with by us, and we see no reason whatever to add to what we have already said about them. On the new points raised in the letter, Mr. Rawson takes for granted that a price which is incorrect is incorrect in the direction he wants it to be. We are not satisfied that the reasons he gives settle the question. Many other points assume the success of the Elmore process, which is, of course, all very well for Mr. Rawson, but may be held under reserve by others. We may say, with all respect, that, in reply to our crucial questions, we expected something more than an italicised "can" and "are." There is a P.S. which shows Mr. Rawson to have been a diligent reader of Mr. FitzGerald's letter. We will leave Mr. FitzGerald to reply to the questions asked him, and for our part we ask Mr. Rawson to kindly refer again to Mr. FitzGerald's letter, where he will see the plural number is largely used throughout, as it almost invariably is in scientific articles or papers dealing with data actual or suppositious. Mr. Rawson must try again. He should not seize upon such slender data to father upon an individual an article for which the Editors of the ELECTRICAL REVIEW are alone responsible.—EDS. ELEC. REV.].

#### Reviews.

I will only so far break through the rules of journalistic etiquette as to say that your recent critique on my "Practical Electrical Notes," second edition, is somewhat severe.

But you make a direct misstatement when you say that the machines are undescribed. *Vide* page 164 *et seq.*

Now, as such a statement is likely to do my book real harm, and as it is quite incorrect, I trust you will do me the justice of inserting a correction in your next issue.

W. Perren Maycock.

[Our reviewer admits that there are descriptions, of the trade circular description, but they are not full enough to be of much value.—EDS. ELEC. REV.]

#### Improvements in Telephone Exchange Switchboards.

The articles in your impressions of October 24th and 31st on the above subject are, without question, of considerable interest to all persons connected with telephonic enterprise in this country, and perhaps in a greater degree to those who are in charge of foreign systems, and have not opportunities of making themselves personally acquainted with the various developments and improvements which are from time to time being made.

After carefully reading the two articles in question, it seems that something more may with advantage be said on the subject of switchboards for small exchanges. Without doubt, both the double and single cord systems have individual points which are valuable, and which cannot easily be obtained by combination, and it therefore becomes a question as to which system gives the greatest efficiency.

When comparing the two systems, it may, in the first place, be said that it is objectionable to have in a telephone circuit more contact points than are absolutely necessary. Therefore, in principle, the single cord system is preferable, and it remains to be seen whether this advantage can be retained in practice satisfactorily. I do not hesitate to say that it can, and that other advantages can also be obtained.

The points to be aimed at are :—

1. A celerity in operation and general efficiency.
2. Simplicity in the arrangement of the circuits, and freedom from more circuit breaks than are necessary.

With regard to these points—

1. (a) Mr. Kingsbury claims that the number of movements in effecting a connection and disconnection of two wires is the same on both boards. On the single cord board the three first movements given by Mr. Kingsbury are in reality of much less value than is attributed to them. They certainly are not equal to more than  $1\frac{1}{2}$  movements, as the plug used is the same in each movement, and any one who has been accustomed to operate both boards will find this to be so. Therefore, I make the operating of the single-cord board equal to, say,  $5\frac{1}{2}$  movements, and the double cord board to 7 movements. Mr. Kingsbury asserts that the double cord movements are done more quickly. I do not see what reason he can give, and in practice it is not the case. On single cord boards of the latest design only four movements are required, if an automatic ringing machine is employed, and five if the ringing has to be done by hand. Therefore, as far as celerity is concerned, the single cord system has the advantage.

(b) The single cord system has been in use for some years, and, when properly fitted, has, as far as I am aware, had no objection of importance brought against its efficiency.

2. As to simplicity of circuits, &c.—When two lines are connected on the single cord board there is only one point of contact, *i.e.*, that between the called plug and the calling jack. On the double cord board there are four, *i.e.*, two plug and spring jack contacts, and two contacts in the key which is inserted into each pair of cords to enable the operator to speak and ring. Every practical telephone man will agree that nothing gives more trouble than key contacts, and this is why they have been entirely done away with on the single cord boards.

It is evident that keys might have been fitted on the latter, and that if this had been done the movements required to effect a connection and disconnection would have been reduced to four as compared with seven on the double cord board.

Mr. Kingsbury refers to the size of the single cord board described in your article of October 24th, and I agree with him that it might be reduced, and this can be done without in any way causing the difficulty in the plugs as he suggests. This is not an important point, however, as it is not usual to place two one hundred line boards side by side. From some cause or other it is usually found advisable to put in a new board when the exchange outgrows the capacity of the existing one. The boards are made for 30, 50, 100, and 150 lines in the style shown in the diagram of October 24th. The canopy pattern board is used for larger sizes. The "cross connections" are therefore never necessary. Mr. Kingsbury points out that the double cord board which he advocates as being the best is only 23 inches wide, and is for 100 subscribers. "Thus 500 subscribers would occupy a space of less than 10 feet." I need only say that it would be quite impossible to work 500 subscribers in a space of 10 feet. In the majority of exchanges two operators are required for 100 to 130 subscribers, and seven to ten operators cannot work with a sitting space of 16 inches in the one case and 10 inches in the other.

I think it has been shown that there is a saving in operators' work on the single cord system, and that other advantages, such as absence of keys and their accompanying faults are obtained.

H. F. Jackson.

December 3rd, 1890.

Since writing the above letter I have seen the further correspondence in your issue of December 5th. Mr. Kingsbury writes at great length in explanation of his previous letter, but without, it seems to me, entering on any new ground with the exception of the question of accessibility. All the working parts of a single cord board can readily be reached from the back, whereas the operators must be interfered with if any fault occurs in the key-board of the double cord system.

H. F. Jackson.

December 8th, 1890.

#### Seeing by Electricity.

With reference to your note *re* "Seeing by Electricity," *Phainein* means to show. Granted; but we want to express not showing, but seeing by electricity. The positiveness of the assertion—"telope," is certainly not right, as "*ope*" represents nothing connected with the subject—appears crushing; but its author seems unaware that *ops* means the eye, and that "OP" is the root from which comes the words most commonly used in the Greek language with regard to sight, to wit, *omma*, the eye; *opsis*, sight; the fut. aor. pass. and pft. mid. of *horao*; and it would not be surprising if the words connected with *skopos*, which we get in telescope, and mean, generally, reflection based upon sight, were all derived from the same root. *Telephane* is a sweet-sounding word, but it does not quite fulfil the required conditions. Why did so severe a maker of words write *optikos* nom. masc. sing., and then *phanerous* acc. masc. pl.? *Teleopt* would not do, as by itself it might easily be supposed to mean—roasted from a distance.

A. C.

#### Incandescent Lamp Breakages.

Would you kindly inform me if any explanation can be offered as to the reason why fully 80 per cent. of breakages in lamp filaments occur from  $\frac{3}{16}$ th to  $\frac{1}{4}$ th above the spot where the end of the filament is cemented to the platinum.

The lamps to which I refer are Edison-Swan 55 v. 8 C.P., and are Brush capped. They are used for ship-lighting. Is it possible that vibration may be a prime factor as to the cause.

Hoping you will pardon my troubling you.

Walter Poyton,  
Electrician R.M.S., "Oroya."

## ELECTRIC LIGHTING COMPLAINTS.

THE recent destructive fire at the Grosvenor Gallery station of the London Electric Supply Corporation, Limited, followed by a second disaster, which completely broke down the partially repaired transformers which had been previously damaged in the conflagration, has been the means of effectually stopping the supply of electrical energy to every customer in the district covered by the Corporation. How long this delay will continue we are unable to determine; but the misfortune which has befallen the supporters of the high tension scheme seems likely to be followed by a host of minor failures which will probably affect electric lighting companies generally. A glance at the columns of the *Times* reveals a state of affairs which does not, to a casual observer (that is if the Parliamentary question of Mr. R. Chamberlain, M.P., into the doings of a well-known supply company should be successful in throwing dust into the public eye), suggest that would-be consumers can yet place a proper degree of reliance in the *bonâ fides* of electric lighting systems. This gentleman has taken it upon himself to ask in the House whether the attention of the Board of Trade had been called "to a long continued default of the Chelsea Electric Supply Company to furnish the statutory current of 100 volts, and to the serious loss of illuminating power sustained by consumers in consequence?" He also desired to know whether the Board of Trade would take steps to compel the company "to keep faith with the public, or forfeit their concession?" Mr. Irving Courtenay, the chairman of the Chelsea Company, in a letter which appeared in our daily contemporary on Monday last, completely demolishes, to his own satisfaction, Mr. Chamberlain's implied charges, but as his communication is directly followed by another from the M.P., reiterating his Parliamentary statements, the public may not easily be able to discriminate between the rights and wrongs of the matter at issue.

Mr. Chamberlain contends that the lamps supplied

by the company are intended to be used at 100 volts terminal pressure, and he finds that, notwithstanding repeated complaints, he gets only 96 to 98 volts. He is apparently ignorant of the fact that the Board of Trade allows a variation above and below of 4 per cent., and it is on this point that the company justifies itself.

Mr. Chamberlain asserts that, with a pressure of, say, 2 to 4 per cent. below the specified voltage, he is left in semi-darkness; but in this he exaggerates, for Sir David Salomons has shown that for a loss of somewhat more than half the light, the fall in voltage must be about 10 per cent., whereas double illuminating power can be gained by an increase of 4 per cent. over the normal difference of potential. It is possible that the company might endeavour to keep nearer to the 100 volts for the sake of pleasing its customers; but, as we imagine the conditions under which supply is guaranteed are known to householders, it will be seen that the complaint, if any, should be directed not against the Chelsea Company but against the Board of Trade for having allowed so much latitude to suppliers.

There are other letters complaining of the uncertainty of all consumers getting current during the time when the London Electric Supply Corporation was generating electrical energy, but it is well known that in early days the demand was greater than the supply, and altogether we fear that the correspondence in the *Times* will have a damaging result upon electric lighting if some steps are not promptly taken to counteract its ill effects.

We have many times pointed out the difficulties which must be encountered in keeping the insulation of high-tension apparatus intact, and the interesting experiences of Mr. Gisbert Kapp, to which we refer in another column, completely bear out our contentions with regard to transformers. It will also be remembered that Mr. Ferranti's mains have come in for their share of criticism at our hands, and we cannot but think that the concluding remark in his letter (see our

Correspondence columns), with regard to his opinion on insulating materials, will not prepossess electricians in his favour, but, doubtless, the advocates of the insulator which he so ruthlessly puts aside will have something to say in its defence, although that is hardly required.

India-rubber has been tried and proven, although in some instances faulty design of leads, or ignorance of the precise purposes for which they were required, may have led to failure of insulation; but the Ferranti conductors have not yet been through that test of time which is necessary in order to show whether they confirm the views of their designer, or come to the end which has been prognosticated in other quarters. Mr. Ferranti's belief in his mains is unbounded, but he admits the difficulty of insulating both generators and transformers under an alternating difference of potential of 10,000 volts; now that work has been shut down for a time, would it be too much to ask the London Electric Supply Corporation to carefully consider its future, and to seriously entertain some modification in its high-pressure method, if that future is to be either technically or commercially successful?

The Corporation must not merely debate its own position *per se*, but it should give due consideration to the many firms whose work in wiring and fitting is largely dependent on the increasing number of its customers, for these contractors suffer as well as the public.

We have often urged that a failure, or even a partial stoppage of the Deptford works, would be disastrous to the electric lighting industry; we fear that the truth of our warnings, which were then disregarded, are beginning to make themselves apparent, and we would, as friends, also suggest to Mr. Ferranti the absolute necessity of thoroughly reconsidering his plans. He has now by sheer misfortune got the opportunity for which he has always asked, a period of inaction in which to bring every part of his producing and distributing plant into thorough order, and we trust that he will, notwithstanding a heavy secession of consumers, neither shorten the time that is necessary for perfecting his work, nor spare any effort which shall tend to render a repetition of the mishaps impossible in so far as human ingenuity can be sure.

To guard against men of Mr. Chamberlain's stamp, we would strongly advise electric light companies to hold as near to their undertakings as possible, and not to merely keep within the limits of the percentage allowance. Judging from the eulogistic terms in which some supporters of the Kensington House-to-House Electric Supply Company speak, it is not a serious matter to give customers exactly what they expect and to which they are entitled.

High-Pressure  
Alternating Mains.

FOLLOWING the reading of Mr. J. Swinburne's paper on "Alternating Current Condensers," at the Physical Society, there was a discussion which drifted from the subject of the paper into a speculation on the alleged rise of E.M.F. in the Ferranti mains. Prof. Ayrton

stated, and he was supported by several other speakers, that the difference of potential taken from a transformer at Deptford was 80 volts, whereas at the Grosvenor end it measured 100 volts. This enormous rise seemed inexplicable, and various theories were advanced with a view of accounting for the possibility of such a phenomenon. Prof. Ayrton referred to a conversation he had had with Mr. Ferranti, which revealed the fact that no direct measurements were made at the termini of the mains themselves, and it has occurred to us since that there might be an error somewhere, and it would be both instructive and interesting if the low-tension transformers at both ends were transposed, viz., the Deptford one to Grosvenor, and that of the Grosvenor to Deptford, and fresh measurements made. We have an idea that the results would then turn out differently, since it is just possible that the transformers themselves may be to blame for this variation; they do not always give that which they are "calculated" to produce, and it seems hardly credible that there could be an unexpected rise of 25 per cent. entirely due to inductive effects; the dimensions of both transformers, we assume, being similar. Mr. Kapp related an interesting experience of his own, when he fruitlessly endeavoured to transform 1,000 into 14,000 volts; he failed entirely in the attempt, in spite of all ordinary care with insulation, the high tension transformer breaking down in every case in a remarkably short space of time. Every day it seems to become more certain that the 10,000 volt craze is giving way, and it seems a great pity that several hundred thousand pounds should have been spent in proving that which could have been as conclusively shown with as many shillings.

Experiments with  
Selenium Cells.

THE last meeting of the Physical Society was unusually attractive. Mr. Shelford Bidwell, F.R.S., told us a great many useful facts about selenium cells and their behaviour, and he gave several experimental illustrations, the most effective of which points to practical applications. Mr. Bidwell connected one of his selenium cells with a delicate relay, which in its turn caused circuit to be established with an automatic switch and an electric lamp. So long as sufficient light impinged upon the selenium the electric lamp did not act, but directly the gas (or daylight in practice) diminished to a certain degree the electric lamp shone forth in its glory, and again became extinguished when its rival reappeared. The fact of any light going out could thus be signalled to a distant attendant, and this would be useful in case of ships' lights and numerous other purposes. The effect of different coloured glass interposed between the light and the cell revealed peculiar results upon the properties of the selenium, and Dr. Thompson suggested that one could almost imagine the near possibility of seeing by electricity if the effects of colours could be transmitted to distances in some analogous manner.

Professors on the  
Technical Press.

PROF. AYRTON, at the Institution of Electrical Engineers, gave his reply to the various points raised during the discussion of the papers on Secondary Batteries. We give an abstract of this reply, and we only refer here to certain remarks which fell from the professor's lips about scientific journals. His attention being called to a letter which Mr. Swinburne wrote to a contemporary a few years ago, Prof. Ayrton said that he could not be expected to read all the matter in an electrical journal,

considering that he had scarcely time to attend to his own correspondence, but almost in the same breath he opened a mild attack upon a leading article on Secondary Batteries which appeared in the *ELECTRICAL REVIEW* on the 25th July last. Prof. Ayrton devoted so much time and attention to this article that we shall discuss at an early opportunity the questions touched upon at last Thursday's meeting.

#### Unsatisfactory Work and its Results.

THAT misfortunes never come singly has been amply shown by the lamentable results of the recent fire at the Grosvenor Station; and even this is supplemented by a serious accident which has occurred at Nancy (France) where the Ferranti system is in use. In this case a horse was instantly killed through receiving a shock, whilst the rider or driver also received a shock, and had to be conveyed to the local hospital. The E.M.F. of the alternators was 2,400 volts, but the accident was not caused by the system employed, it being due to the loose method in which it had been carried out. The cables used are concentric, insulated with jute and hemp, and laid directly in the ground. Where branches and connections to subscribers are made, cast iron boxes, laid from 20 to 24 inches deep, are provided, and after the connections have been made the boxes are filled with *brei*, which is a kind of tar. Since the station was started the insulation of the cables has been found to be defective, and numerous "earths" have taken place—and no wonder. Now that a horse has been killed, and a man seriously injured, the Nancy authorities are investigating the causes of the accident.

#### Oil Engines.

IT is somewhat difficult to understand how oil or gas engines can be conveniently and economically employed for traction, tramcar, or fire engine purposes. Yet, of the three latest oil engines introduced, the makers of two of them state that their engines are very suitable for such purposes. In this connection an industrial contemporary (usually above suspicion), when describing a new oil engine a few weeks ago, actually reproduced the maker's statement to the above effect. It is, however, satisfactory to note that in the description last week of a new oil engine, for which such claims are put forward by the maker, our contemporary wisely refrains from giving them publication.

#### The Rubicon Passed.

THE feverish excitement which followed the floating of the Anglo-American Brush Electric Light Company is now past history, though doubtless there are still many victims who have reason to deplore their folly in attempting to become wealthy by a stroke of the pen. Though the fever is no longer violent, it still shows fitful signs of being in existence, but it is steadily diminishing, and a healthier state of things has resulted. Amusing accounts which used so frequently to come to hand of people's ideas of the electric light are no longer met with; even in the most out-of-the-way places a fairly just estimate of the commercial value of the electric light seems to be arrived at, the inevitable result being that sound trade is becoming brisk and prospects of a brilliant future for electric lighting daily become more certain. The powers being sought for by several municipalities for carrying out electric light work themselves are certain to lead to others following in their steps, and must lead to the employment of many electrical engineers, of whom there is not likely to be any dearth. The last 10 years has been not altogether an encouraging time, but those who have had the patience and stamina to hold on are now likely to reap their reward.

#### Lamp Rheostats.

OUR American contemporary, the *Electrical World*, in describing an arrangement of lamp socket, by which, on turning the switch, the amount of light obtainable can be graduated by successive steps, as in an ordinary gas burner, makes the statement that the amount of heat developed (in the graduating resistance) after an hour's burning is not so great as to render the socket unbearably warm, so that it will be seen that the loss through heat waste has been reduced to a minimum. It is perhaps almost unnecessary to point out that this notion is an utter fallacy, the amount of heat generated in any case is an invariable quantity, and because it is *masked*, as it were, it none the less exists. The users of incandescent lights have often asked, "Can you not furnish us a light which is capable of being turned down just as gas is?" We believe in most cases the object of the consumer in asking for this is not so much to diminish the light as to effect an apparent saving in money. Probably if he knew what a very small diminution in energy is saved when the illuminating power of a lamp is cut down to, say, one-half, he would not consider it worth while to have the contrivance he asks for, though there are cases, of course, where it would be useful.

#### Heavy Dividends Coming.

THE electric light companies of London must soon report progress to the Board of Trade; that is, they must take stock of themselves up to the last day of this month. It is said that there will be no dividends; but shareholders are not to trouble on that score, for it is believed that the companies have almost reached that point after which their receipts will be almost entirely clear profit. In other words, the cost of producing electrical energy for, say, double or treble the present number of lights, will be so little increased in proportion, that the income derived from future customers will be almost wholly available for making the fortunes of stockholders. This, at all events, is the purport of a long article in the *World* of Wednesday, and we must congratulate Mr. Edmund Yates in being able to place the subject so temptingly before his readers, many of whom will doubtless rise to the bait. Even if they do not move a yard beyond the present areas allotted to them, says our contemporary, the companies ought to make enormous fortunes over and over again before the end of their 42 years. We only hope they may.

#### Simple as A B C.

FURTHER on the *World* endeavours to show that electric lighting is so simple that the notion that there is something specially dangerous in it is sheer delusion. "You may, if you like, easily blow up your house with gas; the utmost mischief you can do with your electric wires is to spoil them." "The current is so weak when it enters your house that a baby may play with it." "What danger there is exists only at the central stations or at the subsidiary stations where the current is 'transformed' for customers." "The only damage to which customers are liable—that of being left in sudden darkness by an accident to the wires—is being obviated by double machinery and by connections between subsidiary stations." The *World's* electrical contributor makes things look bright commercially, but when he rises to technical points his remarks make one feel sad to think that there is so little to learn after all these years of study.

## THE EXPERIMENTAL DEMONSTRATION OF VALENCY BY ELECTRICITY.

It is impossible to proceed very far in the study of physics without trespassing upon the domains of the sister science, chemistry. Indeed, many of the most interesting questions which to-day engage the attention of scientists lie just on the borderland, as it were. The knowledge which has been acquired respecting the character of the "atom" and the "molecule" is entirely of a physico-chemical nature, and the pursuit of more knowledge respecting these obscure entities—if such they be—necessarily involves the services of the disciples of both sciences.

Leaving generalities, let us take a particular case. No electrician can hope to fully understand all that has been learnt respecting the internal working of a galvanic battery, much less can he hope to advance knowledge in this direction unless he have at least grasped the principles of the science of chemistry, and has made himself familiar with the various reactions and decompositions which are likely to result when substances are placed in intimate relation. And we take the opportunity of urging all such as are engaged in those departments of electricity which are concerned with the use of batteries, &c., to combine with their electrical knowledge a knowledge of the leading outlines of chemistry at the very least.

Most of our best electricians are tolerably good chemists. Few discoveries are now made *accidentally*; they are the result of intelligent, organised work and laborious investigation. There is, therefore, the greater need for thoroughness.

We have written in this strain more by way of apology than with the idea of leading up to a directly-interested question, although partly to introduce something which is perhaps of a more distinctly chemical than of an electrical nature.

Our readers may remember an illustrated article which appeared in our issue for October 24th on the subject of the action of the electric arc upon gaseous substances. The apparatus therein described may be utilised in order to demonstrate a most important matter in chemistry. And we commend it to the notice of such of our readers as have already embarked upon the right course, and combined with their knowledge of physics some knowledge also of the sister science.

In studying chemistry we are soon confronted with mysterious symbols which, to the uninitiated, are simply bewildering; but we soon find out that they are the "short-hand" of the science, and, moreover, that they assist us to perceive, and, if necessary, to explain, with great rapidity, matters which would otherwise be difficult to grasp.

Chemical formulæ, or symbols, are, to a great extent, based upon certain assumptions regarding those properties of atoms which are referred to under the name *valency*. It is found that the atomic weight of an element is, in some cases, equal to its combining weight, whilst in others it is twice, three times, four times, &c., as great. In other words, an atom of certain elements can be substituted for, or can replace, only one atom of hydrogen, whereas the atoms of other elements can replace 1, 2, 3, 4, &c., atoms of hydrogen. This difference of saturating, or combining power, called by the older chemists *atomicity*, is now appropriately termed *valency*.

The meaning of this term is rather difficult to explain experimentally; according to Lepsius, in a recent paper in the *Berichte der Deutschen Chemischen Gesellschaft*, the apparatus shown in the article which we have already referred to (see page 482) can be used with great success for illustrating this peculiar property of the element.

Four such apparatus of dimensions, each 35 mm. in diameter and 150, 200, 250, 300 cc. capacity respectively, are so arranged that the uppermost stop-cocks are all at the same level. They are then filled with equal volumes, say, about 100 cc. of the following gases: Hydrogen iodide [ $\text{HI}$ ], hydrogen sulphide

[ $\text{H}_2\text{S}$ ], hydrogen phosphide [ $\text{H}_3\text{P}$ ], and hydrogen carbide (methane) [ $\text{H}_4\text{C}$ ] respectively, the volume being marked on the tube immediately after the introduction of the gas.

The arc is now ignited by turning on the current in each of the four apparatus, either separately or simultaneously; this decomposes the gases into their several elemental constituents. They are then allowed to stand at rest for some time in order to allow the contents of the tubes to cool and the pressure therein to become adjusted. When these conditions are fulfilled the volume of the liberated hydrogen in the four tubes is seen to be in the ratio of

$$1 : 2 : 3 : 4$$

showing that the formulæ given above correctly express the relations of the constituents of the substances experimented on; in other words that iodine is monovalent, sulphur is divalent, phosphorus is trivalent, and carbon is tetravalent.

This apparatus may be advantageously used for lecture demonstrations.

## SOME FACTS CONCERNING GUTTA-PERCHA.

(Continued from page 708.)

THE third phase of the second of the two periods into which the history and investigation of gutta-percha are divided, is indicated by the explorations of M. Burck, the director of the botanical gardens at Buitenzorg.

The report of M. Seligman-Lui, on his return to France, impelled the French Government to ask the permission of Holland for the dispatch of a properly equipped expedition to explore Sumatra for the purpose of obtaining gutta-percha plants, with the object of attempting their cultivation in Cochin-China. This request was not granted, and the reason given for the refusal was that the natives of the interior, the Bataks, were divided into many tribes perpetually at war with one another, and the Government could not allow itself to be placed in a position of moral responsibility towards travellers over whom it could exercise no protecting influence. Strangely enough, at this very moment, M. Burck received instructions from the Dutch Government to undertake precisely the same investigations. It is to be presumed that the Bataks were then temporarily at peace with one another.

During the course of his explorations M. Burck observed 14 varieties of gutta-percha trees, among which he was only able to select two having any useful properties. These were the *Niatouh balam tembaga*, from Ampaloo, a species he described as being new, and giving a gum of excellent quality, and the *Payena Leerii*, well known already, and supplying a gum of second class quality.

The other specimens belonged to the following varieties:—

- Tembaga*, from Halaban.
- Bringin* and *Tembaga*, from Soupayang (the *Bringin* is nothing else but the *Payena Leerii*).
- Dourian*, from Halaban and Kayon Tanam.
- Pissang*, from Halaban.
- Bindalou*, from Halaban and Sagoh mountain.
- Selindit Pipit*, and three varieties of *Niatouh balam*, from Pouar-Dastar, Labouei, and Ampaloo.
- Niatouh balam*, from Glougour.

M. Burck brought back to the museum in Java the flowers and gum from the *niatouh balam tembaga*, but throughout the forests situated between Sialang and Glougour he only succeeded in discovering one adult growing specimen of this tree. He found, in every direction, nothing but large trunks lying where they had been cut down, and the natives assured him that the same condition of affairs existed in the districts of Sidjounjung. It took M. Burck a whole week to find the single specimen above referred to, and the forests

he explored were very little frequented, and have only recently been taken possession of by the Dutch Government. Some 75 young plants of the *niatouh balam tembaga* were obtained, and sent to the garden at Buitenzorg.

M. Sérullas proceeds to give an account of the circumstances which led to his investigations in search of a better variety of gutta-percha than discovered by late explorers, the idea of the French Government being to create a nursery at Saigon, so as to perpetuate, by cultivation, the better classes of percha so rapidly becoming extinct. No specimen of the *Isonandra* had been met with for more than 30 years, and the claims of the Buitenzorg gardens to the possession of young plants of that species were easily disproved. The plants obtained from the English and Dutch authorities were not of a suitable class, and those collected by M. Seligman-Lui had been lost.

The author, during the course of long exploration, met with a considerable number of adult trees of the *taban merah* and *taban soutra* among the forests frequented by wild and independent tribes on the Malay peninsula. Suffering from severe attacks of fever, M. Sérullas was compelled to seek relief in France, but, restored to health, he speedily returned to Malaysia, and, after much difficulty, succeeded in transporting to Singapore a number of the young plants of the two species above mentioned. While awaiting the decision of the Government of Cochinchina as to the disposal of the plants, M. Sérullas, greatly to his astonishment and delight, discovered *bona fide* specimens of the *Isonandra gutta Hookerii* in the ravines of Boukett Timah, in the interior of Singapore. This was indeed a fortunate chance, since for forty years the *isonandra gutta* had been searched for in vain.

On the communication of this discovery to the Governor at Saigon, the order for the transport of the young plants of the *Taban Merah* and *Taban Soutra* was revoked, and instructions given to send to Saigon the plants of the *Isonandra*. This was done, but notwithstanding all the careful advice given by M. Sérullas as to the treatment of the shoots, they were allowed to perish through want of attention. The seeds of the *Isonandra* were then obtained, and sent to Saigon, but M. Sérullas, in obtaining these seeds, became affected with chronic dysentery of so violent a form as to necessitate his return to France. His mission was abandoned, and the French Government ceased to give the matter any further attention. The young plants of the *taban merah* and *taban soutra* were left in the gardens at Singapore.

In attempting to arrive at some practical conclusion as to the results of the explorations undertaken by Government officials, M. Sérullas points out the errors into which many investigators have fallen. It has been too generally believed that there existed a particular and defined substance, possessing certain especial chemical characteristics, called *gutta-percha*, and all endeavours have been directed to the search of its vegetable source. Instead of looking for a tree whose coagulated sap assumed the form of a gum endowed with all the qualities required in the most delicate applications, the investigators devoted themselves to the elucidation of botanical problems, and to the discussion of questions of nomenclature and botanical classification. To M. Seligman-Lui may be given the credit of directing enquiries into the proper channels. The only type of gutta-percha possessing the necessary attributes, the *Isonandra*, was to be found in Singapore alone, and had not there been met with for more than a third of a century; under these conditions, it was not the same tree which should have been searched for, but a gutta-percha gum analogous to that supplied by the *Isonandra*.

But if the questions regarding trees producing gums of little value, where submarine telegraphy is concerned, are put on one side, it may be assumed that during the second period, that of official explorations, the question has received practical solution. Adult trees producing good guttas have been found; gums, together with botanical specimens, have been obtained from these trees, and it is known where to find them.

The only trees in Malaysia supplying a sap whose coagulation gives a thoroughly good gutta-percha are:—

The *Isonandra percha* or *Isonandra gutta Hookerii*, from Singapore; the *Gueutta-taban merah*, of Malacca; the *Niatouh balam Tembaga*, from Ampaloo (Halaban), Sumatra; the *Mayang-taban dourrian*, of Singgaloungan (Assahan), Sumatra; the *Gueutta-taban soutra*, from the Malay peninsula; and, finally, a tree, to be described later on, which differs but slightly from the preceding varieties, and whose trunk is supported by numerous aerial roots.

M. Sérullas states that the foregoing trees are not of different species in a botanical sense; that no considerable difference exists between their respective guttas; and that they may be considered as varieties of the same species.

The following methods for distinguishing in the forests these varieties from among other gutta-percha producing trees are practical, and are to be absolutely relied upon; (1) all sap which is a gutta-percha of the best class coagulates almost immediately it escapes from an incision made in the bark. This solidified sap becomes a stiff gum, much veined upon cooling after handling in hot water for two or three minutes.

(2) The leaves of these *isonandra* are covered on the under side with a fine, soft, and golden down in young plants and in fresh shoots. Later this down often becomes copper-coloured, and it sometimes disappears altogether in the old branches of large trees. Every *isonandra*, however, whether old or young, will have many leaves either gold or copper-coloured underneath.

(3) Every normal leaf presenting the foregoing features, and coming from a tree whose sap behaves as above indicated, will be found to have on each side of the principal vein from 22 to 35 very delicate and scarcely visible secondary veins; they are completely buried in the cellular tissue.

The preceding characteristics are only to be simultaneously found in the species *isonandra*, and the tree in which they appear may be relied upon to produce a gutta-percha of the best quality.

(To be continued.)

## THE ELECTROLYSIS BY IGNEOUS FUSION OF FLUORIDE OF ALUMINIUM.\*

By M. ADOLPHE MINET.

IN the two notes† which I have had the honour of presenting to the Academy, I showed that I had produced aluminium by the electrolysis of its fluoride in a melted state.

More recent experiments have enabled me to arrive definitely at the composition of the electrolytic bath, which for given values of the *temperature* and *density* of the current at the electrodes, corresponds to the best rendering obtained from the compound experimented upon; I also succeeded in determining the physical properties of the mixture of the salts in fusion, and establishing the formula which connects the constants of the current with those of the electrolyte at various periods.

*Composition of the bath, its properties and its regeneration.*—The bath is composed of a mixture of chloride of sodium and double fluoride of aluminium and sodium, corresponding to the chemical formula, expressed in equivalents:

$6 \text{ Na Cl} + \text{Al}_2 \text{ Fl}_2, 3 \text{ Na Fl}$ ; melting point,  $675^\circ$ ; boiling point,  $1,035^\circ$ ; density at  $820^\circ$ : 1.76; coefficient of dilatation in a melted state,  $5 \times 10^{-4}$ . Electrical conductivity at  $870^\circ$ : 3.1. The electrical conductivity, as a function of the temperature, is calculated by the equation:

$$C_t = 3.1 [1 + 0.0022 (t - 870^\circ)]$$

\* *Comptes Rendus de l'Académie des Sciences.*

† *Comptes Rendus*, February 17th, and June 9th, 1888.

For a current having an intensity of 1,200 ampères, the mass of the bath is represented by a weight of 20 kg. In this case, the density of the current (intensity per square centimetre of active surface), at the positive pole is 1 ampère, the difference of potential is 5·5 volts at the electrodes. The composition of the bath is maintained constant, during the decomposition of the fluoride of aluminium by means of the following mixture. Hydrate of alumina partly dried :

Double fluoride of aluminum and sodium :

Oxifluoride of aluminium :

This mode of alimentation enables the two-thirds of the fluor given off at the positive pole to be replaced.

The bath is kept at the same level by the introduction of a mixture of chloride of sodium and double fluoride of aluminium and sodium, in the proportions given above.

*Relation between the constants of the current and those of the electrolyte.*—This problem resolves itself into two parts. Let  $\epsilon$  be the difference of potential at the electrodes ;  $e$  the electromotive force of decomposition ;  $\rho$  the resistance of the electrolyte, that of the electrodes being disregarded ;  $I$  the intensity of the current ;  $\delta$  the maximum density of the current at the electrodes, for each period studied.

A.—The salts composing the bath are chemically pure.

a. *First period*, from the point when the density of the current at the electrodes is equal to zero, to the point when it is such that the electromotive force of polarisation is of the same value as the electromotive force of decomposition of the electrolyte under consideration. For the lowest points, the difference of potential may be expressed by the relation  $\epsilon = K I$ , the temperature remaining constant. Towards the limit of density, the value of the difference of potential cannot be calculated by a simple formula ; I have, however, in certain cases, been able to determine the formula required. For a temperature of 870°, the maximum density of the current at the electrode, corresponding to the first period of the electrolysis of the bath experimented upon, varies between ·02 and ·03 of an ampère.

β. *Second Period.*—From the moment when the electromotive force of polarisation is equal to the electromotive force of decomposition of the electrolyte under consideration, to the moment when the density of current at the positive pole, with our bath of fluoride, reaches the value of 1 ampère, the difference of potential is expressed by the equation  $\epsilon = e + \rho I$ .

These are the actual figures of the experiment :—

Temperature 882°. $e = 2\cdot15.$ $\rho = \cdot01.$			Temperature 890°. $e = 2\cdot4.$ $\rho = \cdot0014.$			Temperature 980°. $e = \cdot34.$ $\rho = \cdot0033.$		
$\epsilon$			$\epsilon$			$\epsilon$		
I. amp.	Mea- sured volts.	Calcu- lated volts.	I. amp.	Mea- sured volts.	Calcu- lated volts.	I. amp.	Mea- sured volts.	Calcu- lated volts.
130	3·50	3·45	196	3·26	3·26	572	4·23	4·23
150	3·70	3·65	403	4·12	4·17	650	4·48	4·48
175	3·95	3·90	585	5·05	4·97	910	5·30	5·54
215	4·30	4·30	885	6·18	6·29	1,030	5·78	5·74
245	4·60	4·60	...	...	...	...	...	...

The density of the current at the negative pole is only limited by the dangerous heating due to the passage of the current.

γ. *Third Period.*—For densities of current above 1 ampère, the value of the difference of potential can no longer be calculated as a function of the intensity by a simple formula. It rapidly attains a value approaching that of an electric arc, or from 30 to 40 volts.

B. *The electrolyte is mixed with certain proportions of foreign salts ;* salts of iron and of silicium in the case we are discussing. When we keep the density of the current at the positive pole within certain limits, these salts are decomposed according to Sprague's law. These are the figures obtained with a bath from which the salts of iron and of silicium were successively eliminated.

Temperature 810°. (Salts of iron.) $e = \cdot75.$ $\rho = \cdot0093.$			Temperature 840°. (Salts of silicium.) $e = 1\cdot37.$ $\rho = \cdot0089.$			Temperature 870°. (Salts of aluminium.) $e = 2\cdot15.$ $\rho = \cdot0085.$

It is to be remarked that in these last experiments the resistance,  $\rho$ , of the electrolyte remained constant, the composition of the bath of fluoride of aluminium being as indicated at the beginning of this note ; the salts of iron and silicium, which discoloured it, were in very small quantities.

We have also some observations to make with regard to a method of analysing the bath, to the apparatus for measuring the temperature and the electric current, to the phenomena that are observed when, after the passage of the current, the electrolyte re-acts as a secondary battery. These points will be treated in subsequent notes.—*Comptes Rendus*, October 27th, 1890.

THE COMPLEX NATURE OF ELECTROLYSIS.

FARADAY applied the term *electrolyte* to those substances which, like hydrochloric acid, are resolved into their elements by the passage of an electric current. To the act of decomposition by the voltaic battery he gave the name *electrolysis*. In most cases, if a liquid permit the passage of a current of electricity through it, it is decomposed by the conductor, or, in other words, most liquids which possess conductivity are also electrolytes. Of course there are exceptions to this rule ; some liquids, such, for instance, as alcohol and ether, although they are not absolutely non-conductive, are not capable of being decomposed by the passage of a current. The number of these apparent exceptions to the rule is becoming more and more limited as time goes on and they become better understood. Once people thought that acidulated water was the only liquid which could conduct the electric current ; but now it has been proved that a vast number of binary and ternary, and even more complex substances, are amenable to the general law.

The decomposition of a binary substance like hydrochloric acid (H Cl) is comparatively simple. One of the elements goes to the positive and the other to the negative pole.

The decomposition of a ternary salt is more complex. It was formerly explained by saying that the acid was liberated at the positive electrode and the base at the negative. Thus sodium sulphate,  $Na_2 O SO_3$ , was considered to be resolved into sulphuric acid  $SO_3$  and soda  $Na_2 O$ . But now the way of regarding this change has been modified. The sodium sulphate is supposed to split up into potassium, K, and the electro-negative group,  $S O_4$  ; the metal, K, being liberated at the negative electrode, decomposes the water, and in effecting the solution of the salt, forming potash and liberating free hydrogen. Similarly, the electro-negative group,  $S O_4$ , which cannot of itself

exist in a free state like  $\text{C O}_2$ , can, for instance, decompose into free oxygen gas ( $\text{O}$ ) which is evolved, and into anhydrous sulphuric acid ( $\text{S O}_3$ ), which immediately combines with water to form ordinary sulphuric acid, thus,

When we come to deal with still more complicated substances, the decomposition which ensue on their being subjected to the action of voltaic electricity are of a very involved nature. Berthelot, and some of the other French scientists of his school, have carried their researches into many an unexplored direction, and in connection with such research, the names of Kolbe, Kaempff, Brazier, Gossleth, Wurtz, Schoslemmer, and Kekulé, cannot avoid mention.

The latest work upon the electrolysis of complicated substances is reported from Russia, where, before one of the learned societies of St. Petersburg, N. Burp has read an important paper.

Burp considers that the reaction which takes place when fatty acids are subjected to electrolysis is a very complicated one, and cannot be represented by a simple chemical equation. He does not, however, support Kekulé's views. This scientist represented the decomposition of the fatty acids by the following general formulæ :—

But these equations do not represent facts according to Burp. He says the complicated groups are not decomposed into their negative constituents, but that they enter into reaction with water, reforming the original acid and oxygen, and that the latter, on being liberated, oxidises the electrolyte, and thus forms the different products.

The original paper contains a detailed description of Burp's apparatus, the preparation of the pure substances, and a large set of tabularly arranged analytical data of the gaseous products. It is shown also that the nature and relative quantity of the products obtained at the anode vary very considerably with varying concentrations, intensity of current, size and surface of the electrodes and especially with the temperature of the electrolyte.

The opinion on the complexity of the chemical process in the electrolysis of most substances was first pronounced by Bourgoni, and Burp says that his experiments entirely confirm this view.

## UNDERGROUND AND OVERHEAD ELECTRIC WORK.

IN undertaking underground electrical work, it is essential to provide a good and lasting insulating covering for the buried wires, and also some means of protecting the cables from mechanical injury. This is not all that is required, for, so soon as the switch boxes and other connections are joined on as part of the circuit, an insulation of 500 megohms per mile in the cable *per se* will drop to three or four megohms resistance, or even less; besides, after a time, from various causes, a cable may show a perceptible drop in insulation. This drop will often be permanent. In a cable insulated with India-rubber, contact with pitch or similar material has been known to lower the resistance of the rubber; but this does not materially damage the cable for practical purposes, beyond the lowering of insulation, as in other respects it is perfectly sound. The big drops in insulation do not arise from this sort of mishap, but more frequently, as Mr. Degenhardt states in a paper read before the Chicago Electric Club, from bad jointing, moisture, and insufficiently insulated switch boxes; and therefore, in selecting men to do the difficult work of making joints, it is well to secure those of high class character, and instil into their minds the fact that it is not how many joints they can make,

but how well they can do them. There is little to complain of in the quality of the cables employed, as manufacturers supplying them make them to meet the varying requirements of their customers, and accompanied with a guarantee. The underground work in Chicago is a success, proving what can be accomplished by an honest effort to comply with the ordinance of the Common Council, ordering all electric conductors to be placed beneath the surface of the streets. The area ways under the side walks was a favourable circumstance connected with this underground construction, practically forming a ready made conduit. Not every city in the States has this advantage. The conduits in which the cables are placed are of various kinds, viz.: iron pipe laid in the earth without any protection; iron pipe laid in concrete; iron pipe, cement lined, laid in concrete and multitubular blocks of bituminous concrete about 4 feet long. Manholes at intervals, with watertight double covers. The iron pipe used for the conduit is thoroughly reamed at the ends to remove the burr. All pipes are also laid with a grade to draw off condensation water into the manholes. Quite an elaborate set of tools and accessories has been devised for manipulating the cables. Of course, this underground service is not perfect; but we have it on the authority of Professor Barrett that it is safe, feasible, and practicable. With the exception, perhaps, of small cities with small service, overhead systems will soon be things of the past. The people wish to get rid of overhead high pressure wires, so do the electricians, but capitalists do not. The electric light people assemble together from time to time, and they tear the underground service all to pieces. None are so blind as the people who will not see; for instance, some two years back the City of New York appointed a delegation to visit Chicago and examine the underground service in that city. The gentlemen forming the delegation called on Prof. Barrett at his office, and were offered every facility to view the system. They did not avail themselves of the opportunity, but promptly returned home. They sent in a report stating that they had not seen a list of underground work in Chicago, which was true. Next year, one of them again called on the chief of the Telegraph Department, who said to him: "Do you want to make a report on underground work this time?" adding, on receiving an answer in the affirmative, "You are going to see the underground service this time." The delegate was then taken out and deposited in a manhole. If report may be believed, the above is not the only instance of jobbery perpetrated during the long-continued battle between the advocates of overhead and underground systems. It is charged against the upholders (shall we say the capitalists) of the overhead system that in order to bear out their assertion that underground electrical work for electric lighting was impracticable, they deliberately put down cables which they knew would not work, and by their failure produced spurious evidence against the rival system. It is not unreasonable to conjecture that the celebrated pole-chopping incident at New York was the outcome of some disclosure connected with this party spirit.

It is stated that the cost of running underground wires for arc lighting purposes, including cost of conduits, interest on investment, cleaning out manholes, repairs to and the maintenance of cables, and depreciation of the system, is nearly one cent. per hour over the cost of wires carrying the same current overhead. In the long run, this overcharge will amount to *nil*; it is even questionable whether the difference in cost between the two methods is not already overstated, considering it appears to be an accepted fact that a larger proportion of the electric current reaches its destination through the underground mains than by the overhead line.

**Telephony in Iceland.**—A telephone line, about five miles long, has been established in Iceland. It is regarded as a great curiosity, being the first ever established on the island.

NOTES ON ECONOMY IN CONDUCTORS IN  
SYSTEMS OF DISTRIBUTION OF ELECTRICAL ENERGY.\*

(Concluded from page 714.)

## Variable but Uniform Current Circuits.

If the current in a circuit is not a constant quantity—as in the case of series arc lighting—but variable throughout each day, and from day to day throughout the year, the value previously obtained for the most economical current density to employ refers to the square root of the mean square of the current for the year. In estimating or planning a system of mains it is more convenient to think about the most economical current density referred to the maximum current; that is to say, it is better to know that the greatest economy will be obtained in a given circuit if the current density, when the maximum current is flowing in it, is, say 500 amperes per square inch, than to know that you obtain the most economical arrangement if the current density of the square root of the mean square of the current is, say, 300 amperes per square inch.

It is necessary, then, to consider what the ratio of the maximum current to the square root of the mean square of the current is likely to be in a given circuit; and the best way to arrive at this value is by examination of load diagrams obtained from similar districts.

When Prof. Forbes, in 1885, so strongly advocated the most thorough and careful working out of any system of mains to be laid down in order to obtain the most economical arrangement possible, electrical engineers were necessarily very much in the dark as to the data upon which to base their calculations. It is absolutely essential, in order to plan the most economical arrangement possible, to know beforehand what kind of load diagram you are likely to get. Fortunately, we have now a certain amount of experience to help us, but there is no doubt that in this respect the experience of the next 10 years will be most valuable.

I have worked out one or two load diagrams for a single day in order to give an example. For this diagram, which was taken at Boston, the ratio of the maximum current to the square root of the mean square works out to 2.34, and for this second diagram, which was sent out by a town in the West of England in order that maintenance estimates might be prepared, the ratio is 3.57, and for this third diagram the ratio will be between 2.5 and 3.0.

With a slide rule and planimeter it is, of course, a very easy matter to determine this ratio for any given load diagram. The value to be used, however, is that obtained from a complete set of diagrams taken at short intervals throughout the year, and in connection with this it may be mentioned that Dr. Gustav Rasch states that the value of this ratio (as obtained by observations at different central stations during one year, and taking the average value) is 3.41.

To take an example, let us suppose that the cost of a Board of Trade unit is 3d., that the sum of the rates of interest, depreciation, &c., is 15 per cent., that current flows throughout the year in the circuit under consideration, that the ratio of the maximum current to the square root of the mean square is 3.2, and that the cable is 19-stranded Silvertown L. We have thus

$$b = 3.39$$

$$c = 3$$

$$d = 15$$

$$n = 8,760$$

$$\text{hence } D = 3.2 \times 7,513 \sqrt{\frac{3.39 \times 15}{8,760 \times 3}} = 1,058.$$

In this case, then, the most economical current density is 1,058 amperes to the square inch for the maximum current.

This determination of the most economical current density to employ for a given type of cable applies only to cases in which the current density is uniform throughout the cable under consideration. This is so, of course, in feeders, but not in the mains proper of a system of parallel distribution.

In the latter case the current flowing across any section of the conductor diminishes as the distance of the section under consideration increases from the feeding points. If we assume that in the mains between two pairs of feeding points the current taken off per yard is constant, we can determine a multiplier for the most economical current density, obtained on the assumption that the current is uniform between the feeding points, which will give us what is really the most economical (maximum, or at a section very near the feeding points) current density to employ in the mains.

In the case we have supposed it is easy to see that this multiplier is  $\sqrt{3}$  or 1.732. Now if we take, as before, 19-stranded Silvertown L cable, and make the same assumptions as to the cost of energy, &c., we find that the proper size of main to employ is that which gives us a current density of 1,832 amperes to the square inch at a section very close to the feeding points, and when the maximum current is flowing.

In the case of any other law according to which the current

taken off per yard may vary, it is very easy by constructing, firstly, the curve of flow of current along the main, and secondly, the curve of the squares of the current, to deduce the proper multiplier by means of a planimeter and slide-rule.

The process of making the foregoing calculations for any particular case is certainly easy and very fairly rapid, but it is obvious that before attempting to design a set of mains for a particular district, a thorough canvass should be made to ascertain its special requirements.

It should be remarked that the preceding investigation as to the effect of non-uniformity of current in the mains assumes that the load diagrams for the different buildings supplied between two pairs of feeding points are similar in character, a case which in general does not occur in practice, but for which allowance must be made either in the selection of an average load diagram or subsequently by special calculation.

I may end this portion of these notes by observing that though the current density arrived at may seem sometimes rather great, it occurs for such a very limited time that it is not likely to be harmful to the cables used.

## Transmission of Power to Stationary Motors.

The whole of the foregoing relates to general supply of energy from central stations, and the conclusions arrived at were all based upon the fact that in such work you have to maintain a definite pressure at the consumers, so that the current to be supplied is a fixed quantity.

As is very well known, Sir William Thomson first pointed out in 1881, that in such cases the current density to be employed is independent of the length of conductor through which the energy is to be transmitted, and that the proper gauge to employ for a definite current is that which makes the value of the annual waste of energy per mile equal to the interest, depreciation, &c., on the capital laid out in conductor per mile.

There are, however, a large number of cases to which the above does not apply at all, and the transmission of power from a source where it is cheap to a distant point where it is valuable, is one of the most important of these at present.

In a very important paper read by Profs. Ayrton and Perry before the Society of Telegraph Engineers and Electricians, the authors gave, among other things, the solution of the following problem: What is the most economical current density to employ

when a certain power,  $P$ , has to be furnished at the end of  $\frac{n}{2}$  miles,

and when the pressure at the source has been fixed at  $v$  volts?

If  $c$  is the current in amperes,  $r$  the resistance of the conductor per mile in ohms,  $t$  a constant—depending on the number of hours of working per annum, the cost of the cable per pound of copper, the sum of the rates of interest, depreciation and maintenance, and the value of a Board of Trade unit—and,  $F(c, r)$ , the total waste of energy per mile reckoned in watts (i.e., with the interest, depreciation, &c., on the cable expressed in watts as well as the actual waste of energy in the cable), we have

$$F(c, r) = c^2 r + \frac{t^2}{r} \quad (i.)$$

$$\text{and further, } f(c, r) = P - c(v - ncr) = 0 \quad (ii.)$$

From these two equations we have to determine  $c$  and  $r$ , and hence the current density  $D$ , so that  $F(c, r)$  is a minimum.

As you know, the values of  $c$  and  $r$ , which make  $F(c, r)$  a minimum, are those obtained from the equations

$$\left(\frac{dF}{dc}\right) \cdot \left(\frac{df}{dr}\right) - \left(\frac{dF}{dr}\right) \cdot \left(\frac{df}{dc}\right) = 0 \quad (iii.)$$

$$\text{and } f(c, r) = P - c(v - ncr) = 0 \quad (ii.)$$

From these we obtain

$$c = \frac{P}{v} \frac{nt + \sqrt{(v^2 + n^2 t^2)}}{\sqrt{(v^2 + n^2 t^2)}} \quad (iv.)$$

$$\text{and } D = 23.5 \frac{vt}{1 + \sqrt{(v^2 + n^2 t^2)}} \quad (v.)$$

the constant 23.5 being the conductivity of a copper conductor one mile long of one square inch sectional area.

If we put  $\frac{nt}{v} = \tan \phi$ ,

$$c = \frac{P}{v} (1 + \sin \phi) \quad (vi.)$$

$$\text{and } D = 23.5 \frac{v}{n} \left( \frac{\sin \phi}{1 + \sin \phi} \right) \quad (vii.)$$

I have calculated the following table of values of  $(1 + \sin \phi)$

and  $\left(\frac{\sin \phi}{1 + \sin \phi}\right)$  for values of  $\tan \phi$  between 0.025 and 4.0, thus

embracing all practical cases, I believe. (See Table A.)

From this table, or from the curves given which have been constructed from it, it is a very easy matter to determine the proper current density to employ in any given case without any further calculation than that readily performed with a slide-rule.

With regard to  $t$ , its value is obtained from the equation

$$t = 98.6 \sqrt{\frac{LQ}{NU}}$$

\* Paper read before the Old Student's Association, December 4th, by Hamilton Kilgour, member,

where  
L = cost in pence in copper in cable per pound.  
N = number of hours in working per annum.  
Q = sum of the rates of interest, depreciation, and main-  
tenance on capital laid out in cable,  
and  
U = cost in pence of a Board of Trade unit.  
If L = cost in £ of copper in cable per ton, the equation becomes

$$t = 30.6 \sqrt{\frac{L \cdot Q}{N \cdot U}}.$$

I have thought it of interest to members that tables and curves showing the effects produced in a particular case of varying the different quantities, t, v, and n, should be given, and I have there-fore taken the following cases :

- (i.) v = 2,000 volts.  
n = 10 miles.  
t variable between 15 and 50.
- (ii.) n = 10.  
t = 25.  
v variable between 500 volts and 10,000 volts.

TRANSMISSION OF POWER.

(i.) P = 87,700 watts. v = 2,000 volts. n = 10 miles.

400	33.23	262.7	78,440	1,407,600	1,486,000	47.2
450	33.57	238.6	80,140	1,779,500	1,859,700	47.8
500	33.83	218.2	81,426	2,195,500	2,276,900	48.2

In each case the power to be transmitted, P, has been taken as 87,700 watts, which, with motors of 85 per cent. efficiency, will give 100 brake H.P.

The curves (see pp. 500 and 501) and tables show what changes are produced in the different quantities tabulated—the most economical current density being employed in each case. I should mention that in the curves and tables are included P<sub>1</sub>, P<sub>2</sub>, P<sub>3</sub>, and K where

- P<sub>1</sub> = waste of energy in conductor.
- P<sub>2</sub> = interest, depreciation, &c., on capital laid out in cable.
- P<sub>3</sub> = P<sub>1</sub> + P<sub>2</sub>.
- K = percentage loss of volts in transmission of the power in each case.

You will notice that in cases of transmission of power over a considerable distance, P<sub>1</sub>, the power wasted, bears a pretty high ratio to P, the power transmitted, so that the power of the generators must be considerably in excess of that actually required by the motors.

Now the value of v, and hence of t, depends to a certain extent upon the power of the generators (P + P<sub>1</sub>), and it is not difficult to see that this relation can be expressed by the equation

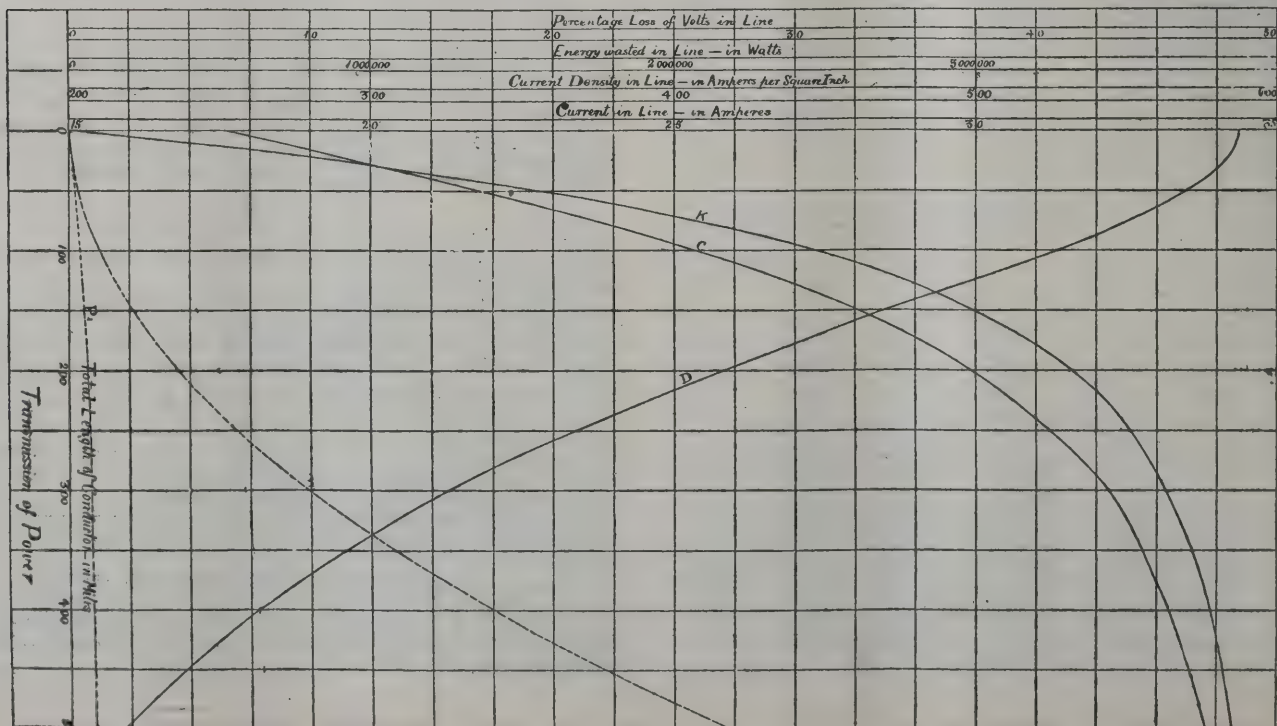

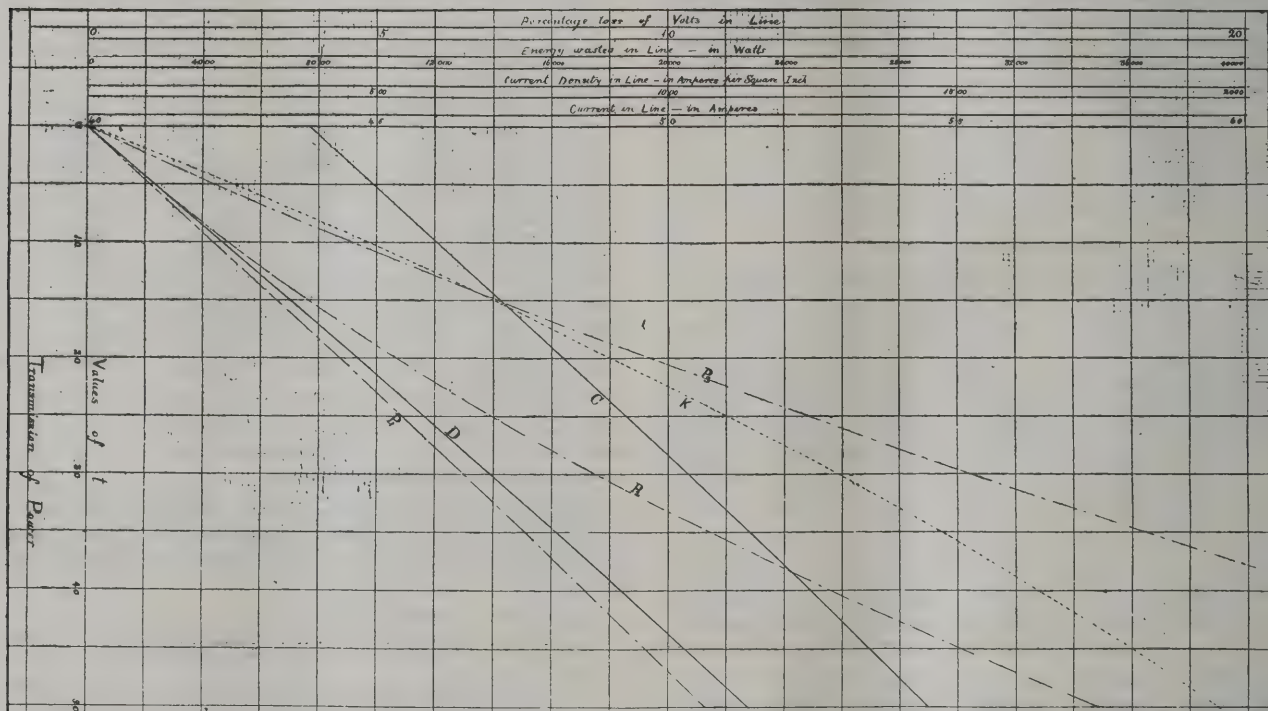

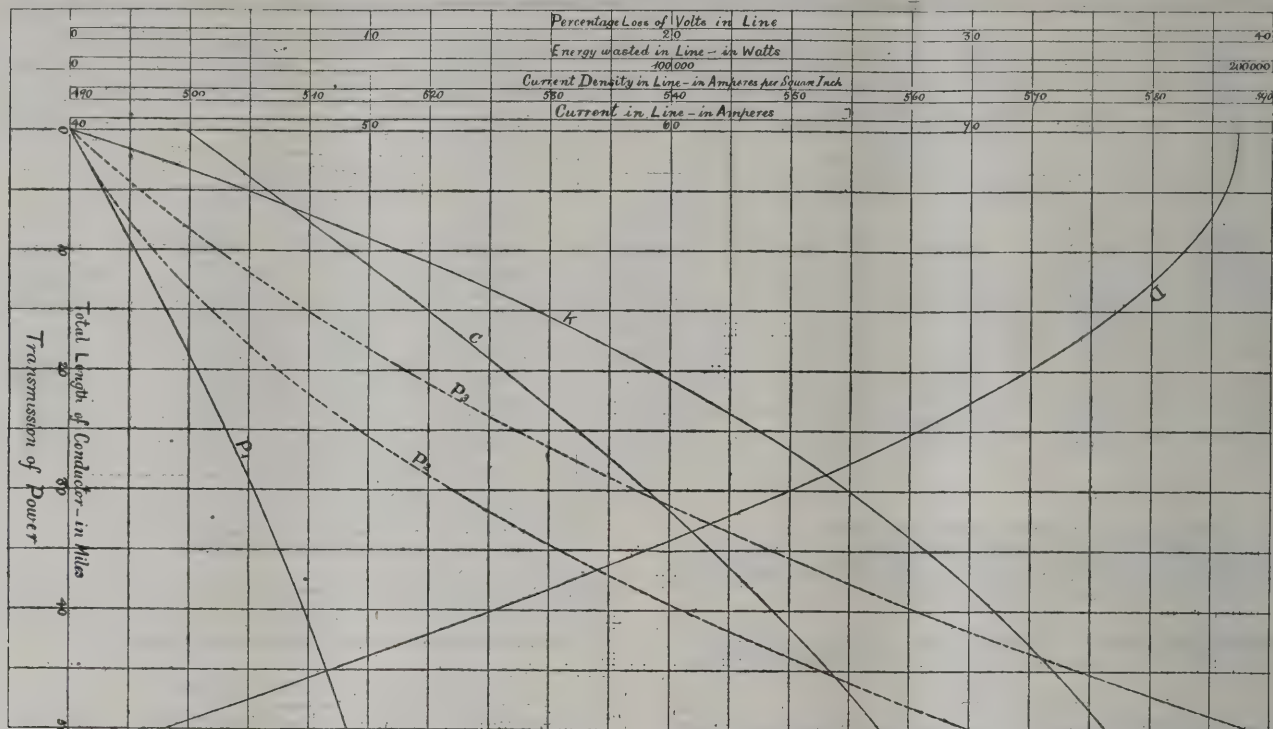

$$t = \sqrt{\frac{P + P_1}{A + B P_1}},$$

where A and B are constants depending on the conditions of the case under consideration.

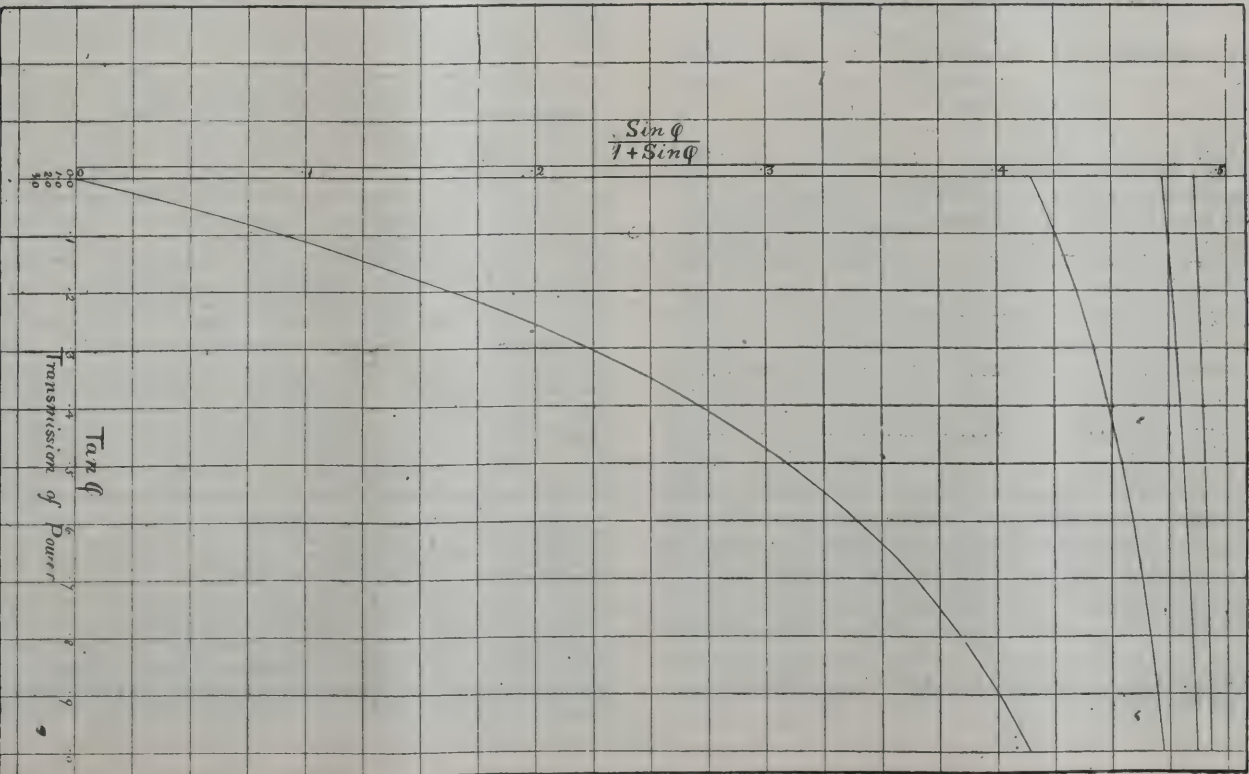

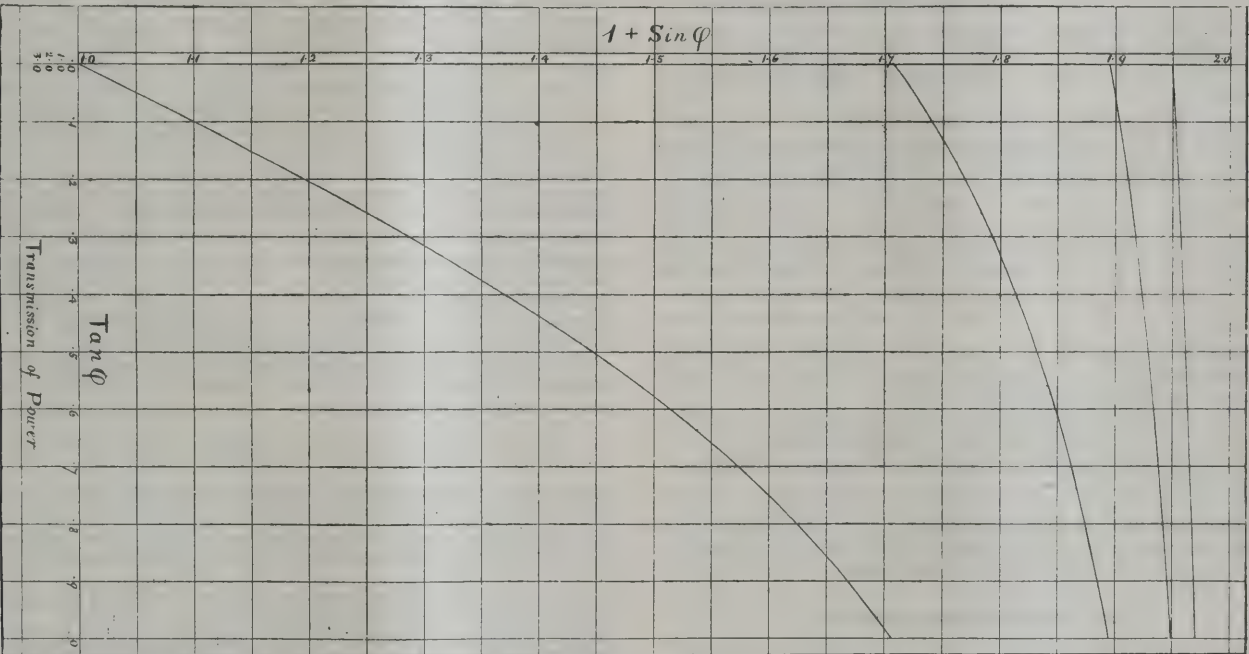

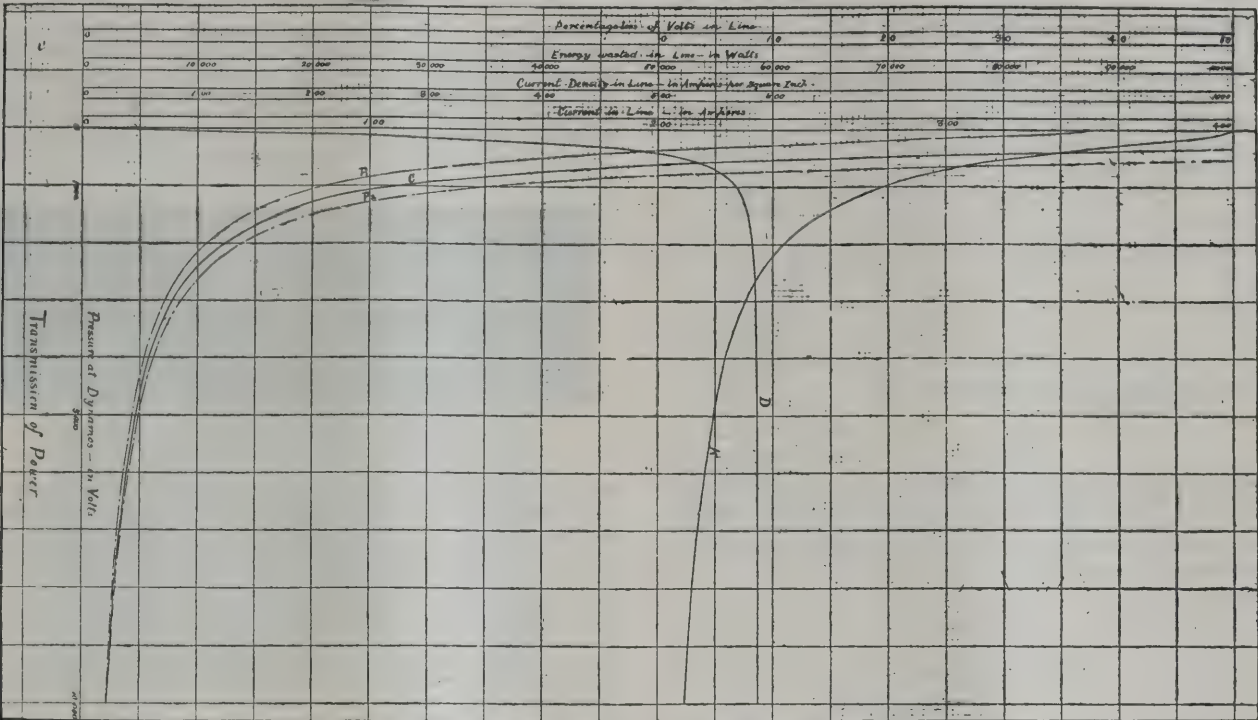

However, from these tables it is easy to judge approximately beforehand what P<sub>1</sub> will be in any given case, so that P + P<sub>1</sub> being known, t can be then accurately estimated, and c and d obtained as before. To take an example, let us suppose that we want to transmit 100 brake H.P. from a waterfall to a mill at a distance of five miles. We will suppose that there is an effective head of 37 feet, that the efficiency of the motors is 85 per cent., that the loss in the line is about 15 per cent., that the generators have an efficiency of 87 per cent., that there is a loss of 5 per cent. in belting, and that we take 2,000 volts as our working pressure.

The power to be transmitted to motors will be 87,700 watts, that developed by the generators 110,000 watts, and that given out by turbines 164 brake H.P.

For the water engines I shall suppose that we use 15-inch Victor turbines, of which the cost, and also that of the accessories, &c., has been kindly furnished me by Mr. Nell, and for the dynamos (motors and generators) I shall take the costs of Victoria machines in this example.

CURVES ACCOMPANYING MR. KILGOUR'S PAPER.

CURVES ACCOMPANYING MR. KILGOUR'S PAPER.

For the case [we] are considering, then, I estimate the costs as under:—

Machinery and line (including posts, insulators, &c., but no cable) ... ..	£2,500
Buildings' foundations, pipes, &c. ... ..	870
Labour (including running of cable) ... ..	750
Sundries ... ..	180

Total ... .. £4,300

Taking then

17½ per cent. on £2,500 ... ..	£437 10 0
12½ " " 870 ... ..	108 15 0
7½ " " 750 ... ..	56 5 0
10 " " 180 ... ..	18 0 0

Total ... .. £620 10 0

Cost of running machinery at both ends, and sundries (say) ... .. 150 0 0

Total ... .. £770 10 0

The total annual expenditure in the production of 110,000 watts is therefore £770 for 2,808 hours (54 hours per week) per annum, or  $v = 0.6d$ ; hence  $t = 26.7$  very approximately if we assume use of bare wire and take copper at 9½d. per pound, and interest, depreciation, &c., on cable at 15 per cent.

Then, since

$$t = 26.7$$

$$v = 2,000$$

$$n = 10,$$

$$\tan \phi_1^* = 0.1335$$

and

$$c = 49.6 \text{ ampères}$$

$$d_1^* = 547 \text{ ampères per square inch.}$$

The necessary conductor would weigh about 10,120 lbs., per mile and cost £390 per mile. In it the loss of power would be about 12 per cent., so that we rather over-estimated it when taking this at 15 per cent.

The following general notes on conductors may be of some use:

Of cables of the same class of insulation, and the same insulation resistance per mile, and the same cross-sectional area, a single wire is the cheapest, and the fewer the number of wires in a strand, the cheaper is the cable. For example, take Silvertown class S, in which the single wires are about 18 per cent. cheaper than the stranded cables of equal cross-sectional area. A concentric cable is generally, as you would expect, considerably dearer than two separate conductors with the same class of insulation and the same insulation resistance per mile between the going and return conductor.

A cylinder of copper of one square inch area and one mile long weighs 20,400 lbs., or 9.1 tons very approximately, and it has a resistance of 0.0425  $\omega$  per mile at 60° F.

Such a cylinder 100 yards long weighs 1,160 lbs., or 0.52 tons, and has a resistance of 0.0024  $\omega$  per mile approximately.

These values apply equally to stranded cables with a high degree of approximation.

With stranded cables the effective area of cross-section and the weight per mile are about 2½ per cent. to 3 per cent. greater, and the resistance per mile is 2½ per cent. to 3 per cent. less than that of a cable composed of the same number of parallel wires.

## THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.

(Continued from page 682.)

If, then, we could take a very long magnet, we may utterly neglect the action on the distant pole. If I had a long steel magnet with the south pole 5 or 6 feet away, and the north pole at a point 3 diameters (i.e., 6 centimetres in this case) distant from the mouth of the coil, then the pull of the current in one spiral on the north pole, 3 diameters away, would be practically negligible; it would be less than 2 per cent. of what the pull would be of that single coil when the pole was pushed right up into it. But now, in the case of the tubular coil, consisting of at least a whole layer of turns of wire, the action of all of the turns has to be considered. If the nearest of the turns of wire is at a distance equal to three diameters, all the other turns of wire will be at greater distances, and, therefore, if we may neglect such small quantities as 2 per cent. of the whole amount, we may neglect their action also, for it will be still smaller in amount. Now, for the purpose of arriving at the action of a whole tube of coil, I will adopt a method of plotting devised by Mr. Sayers. Suppose we had a whole tube coiled with copper wire from end to end, its action would be practically the same as though the copper wire were gathered together in small numbers at distant intervals. If, for example, I count the number of turns in a centimetre length of the actual tubular coil which I used in my first experiment, I find there are four. Now if, instead of

having four wires distributed over the centimetre, I had one stout wire in the middle of that space to carry four times the current, the general effect would be the same. This diagram (fig. 60) is calculated out on the supposition that the effect will be not greatly different if the wires were aggregated in that way, and it is easier to calculate. If, beginning at the end of the tube marked A, we take the wires over the first centimetre of

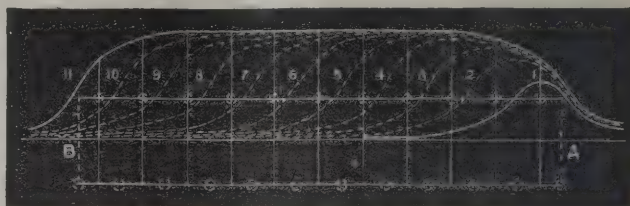

FIG. 60.—ACTION OF TUBULAR COIL.

length and aggregate them, we can draw a curve, marked 1, for the effect of that lot of wires. For the next lot, we could draw a similar curve, but instead of drawing it on the horizontal line we will add the several heights of the second curve on to those of the first, and that gives the curve marked 2; for the third part, add the ordinates of another similar curve, and so gradually build up a final curve for the total action of this tubular coil on a unit pole at different points along the axis. This resultant curve begins about 2½ diameters away from the end, rises gently, and then suddenly, and then turns over and becomes nearly flat with a long level back. It does not rise any more after a point about 2½ diameters along from A; the curve at that point becomes practically flat, or does not vary more than about 1 per cent., however long the tube may be. For example, in a tubular coil 1 inch in diameter and 20 inches long, there will be a uniform magnetic field for about 15 inches along the middle of the coil. In a tubular coil 3 centimetres in diameter and 40 centimetres long, there will be a uniform magnetic field for about 32 centimetres along the middle of the coil. The meaning of this is that the value of the magnetic forces down the axis of that coil begins outside the mouth of the tube, increases, rises to a certain maximum amount a little within the mouth of the tube, and after that is perfectly constant nearly all the way along the tube, and then falls off symmetrically as you get to the other end. The ordinates drawn to the curve represent the forces at corresponding points along the axis of the tube, and may be taken to represent not simply the magnetising force, but the pull on a magnetic pole at the end of an indefinitely long, thin steel magnet of fixed strength.

The rule for calculating the intensity of the magnetic force at any point on the axis of the long tubular coil within this region where the force is uniform, is:—

$$H = \frac{4}{10} \pi \times \text{the ampere-turns per cm. of length.}$$

And, as the total magnetising power of a tubular coil is proportional not only to the intensity of the magnetic force at any point, but also to the length, the integral magnetising effect on a piece of iron that is inserted into the coil may be taken as practically

equal to  $\frac{4}{10} \pi \times$  the total number of ampere-turns in that portion

of the tubular coil which surrounds the iron. If the iron protrudes as much as 3 diameters at both ends, the total magnetising

force is simply  $\frac{4}{10} \pi \times$  the whole number of ampere-turns.

Now that case is, of course, not the one we are usually dealing with. We cannot procure steel magnets with unalterable poles of fixed strength. Even the hardest steel magnet, magnetised so as to give us a permanent pole near, or at the end of it—quite close up to the end of it when you put it into a magnetising coil—becomes by that fact further magnetised. Its pole becomes strengthened as it is drawn in, so that the case of an unalterable pole is not one which can actually be realised. One does not usually work with steel: one works with soft iron plungers, which are not magnetised at all when at a distance away, but become magnetised in the act of being placed at the mouth of the coil, and which become more highly magnetised the further they go in. They tend, indeed, to settle down, with the ends protruding equally, for that is the position where they most nearly complete the magnetic circuit; where, therefore, they are most completely and highly magnetised. Accordingly, we have this fact to deal with, that whatever may be the magnetising forces all along a tube, the magnetism of the entering core will increase as it goes on. We must therefore have recourse to the following procedure. We will construct a curve in which we will plot, not simply the magnetising forces of the spiral at different points, but the product of the magnetising forces into the magnetism of the core which itself increases as the core moves in. The curve with a flat top to it corresponds to an ideal case of a single pole of constant strength. We wish to pass from this to a curve which shall represent a real case, with an iron core. Let us still suppose that we are using a very long core, one so long, that when the front pole has entered the coil, the other end is still a long way off. With an iron core, of course, it depends on the size and quality of the iron as to how much magnetism you get for a given amount of magnetising power. When the core has entered up to a certain

\* Cantor Lecture. Delivered before the Society of Arts, February 3rd, 1890.

point, you have all the magnetising forces up to that point acting on it: it acquires a certain amount of magnetism, so that the pull will necessarily go on increasing and increasing, although the intensity of the magnetic force from point to point along the axis of the coil remains the same, until within about two diameters from the far end. Although the magnetic force inside the long spiral remains the same, because the magnetism of the core is increasing, the pull goes on increasing and increasing (if the iron does not get saturated) at an almost uniform rate all the way up, until the piece of iron has been poked pretty nearly through to the distant end. In fig. 61, a tubular coil, B A, is represented. Sup-

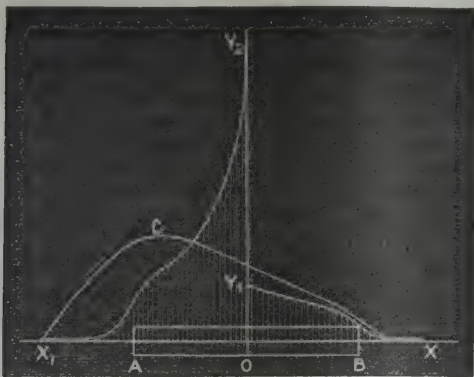

FIG. 61.—DIAGRAM OF FORCE AND WORK OF COIL AND PLUNGER.

pose a long iron core is placed on the axis to the right, and that its end is gradually brought up toward B. When it arrives at x, the pull becomes sensible, and increases at first rapidly, as the core enters the mouth of the tube, then gently, as the core travels along, attaining a maximum, c, about at the further end, A, of the tube. When it approaches to the other end, A, it comes to the region where the magnetising force falls off, but the magnetism is still going on increasing, because something is still being added to the total magnetising power, and these two effects nearly balance one another, so that the pull arrives at the maximum. This is the highest point, c, on the curve; the greatest pull occurring just as the end of the iron core arrives at the bottom or far end of the tubular coil: from which point there is a very rapid falling off. The question of rapidity of descent from that point depends only on how long the core is. If the core is a very long one, so that its other pole is still very far away, you have a long, slow descent going on over some three diameters, and gradually vanishing. If, however, the other pole is coming up within measurable distance of B, then the curve will come down more rapidly to a definite point, x<sub>1</sub>. To take a simple case where the iron core is twice as long as the coil, its curve will descend in pretty nearly a straight line down to a point such that the ends of the iron rod stand out equally from the ends of the tube.

Precisely similar effects will occur in all other cases where the plunger is considerably longer than (at least twice as long as) the coil surrounding it. If you take a different case, however, you will get another effect. Take the case of a plunger of the same length as the coil, then this is what necessarily happens. At first the effects are much the same; but as soon as the core has entered about half, or a little more than half its length, you begin to have the action of the other pole that is left protruding outside tending to pull the plunger back; and although the magnetising force goes on increasing the further the plunger enters, the repulsion exerted by the coil on the other pole of the plunger keeps increasing still faster as this end nears the mouth of the coil. In that case the maximum will occur at a point a little further than half way along the coil, and from that point the curve will descend and go to zero at A; that is to say, there will be no pull when both ends of the plunger coincide with the two ends of the coil. If you take a plunger that is a little shorter than the coil, then you find that the attraction comes down to zero at an earlier period still. The maximum pull occurs earlier, and so does the reduction of the pull to zero; there being no action at all upon the short core when it lies wholly within that region of the tube within which the intensity of the magnetic force is uniform. That is to say, for any portion of this tube corresponding to the flat top of the curve of Fig 60, if the plunger of iron is so short as to lie wholly within that region, then there is no action upon it; it is not pulled either way. Now these things can be not only predicted by the help of such a law as that, but verified by experiment. Here is a set of tubular coils which we use at the Finsbury Technical College for the purpose of verifying these laws. There is one here about nine inches long, one about half that length, another just a quarter. They are all made alike in this way, that they have exactly the same weight of copper wire, cut from the same hank, upon them. There are, of course, more turns on the long one than on the shorter, because with the shorter ones each turn requires on the average a larger amount of wire, and therefore the same weight of wire will not make the same number of windings. We use that very simple apparatus, a Salter's balance, to measure the pull exerted down to different distances on cores of various lengths. You find in every case the pull increases and becomes a maximum, then diminishes. We will now make the experiment, taking first a long plunger, roughly about twice as long as the coil. The

pull increases as the plunger goes down, and the maximum pull occurs just when the lower end gets to the bottom; beyond that the pull is less. Using the same plunger, with these shorter coils, one finds the same thing, in fact more marked, for we have now a core which is more than twice the length of the coil. So we find, taking in all these cases, that the maximum pull occurs, not when the plunger is half way in, as the books say, but when the bottom end of it is just beginning to come out through the bottom of the coil that we are using. If, however, we take a shorter plunger, the result is different. Here is one just the same length as the coil. With this one the maximum pull does occur when the core is about half way in; the maximum pull is just about at the middle. Again, with a very short core—here is one about one-sixth of the length of the coil—the maximum pull occurs as it is going into the mouth of the coil; and, when both ends have gone in so far that it gets into the region of equable magnetic field there is no more pull on one end than on the other; one end is trying to move with a certain force down the tube, and the other end is trying to move with exactly equal force up the tube, and the two balance one another. If we carry that to a still more extreme case, and employ a little round ball of iron to explore down the tube, you will find this curious result, that the only place where any pull occurs on the ball is just as it is going in at the mouth. For about half an inch in the neck of the coil there is a pull; but there is no pull down the interior of the tube at all, and there is no measurable pull outside.

Now these actions of the coil on the core are capable of being viewed from another standpoint. Every engineer knows that the work done by a force has to be measured by multiplying together the force and the distance through which its point of application moves forward. Here we have a varying force acting over a certain range. We ought, therefore, to take the amount of the force at each point, and multiply that by the adjacent little bit of range, averaging the force over that range, and then take the next value of force with the next little bit of range, and so consider in small portions the work done along the whole length of travel. If we call the length of travel  $x$ , the element of length must be called  $d, x$ . Multiply that by  $f$ , the force. The force multiplied by the element of length, gives us the work  $d, w$ , done in that short range. Now the whole work over the whole travel is made up of the sum of such elements all added together; that is to say, we have to take all the various values of  $f$ , multiply each by its

own short range  $d, x$ , and the sum of all those, writing  $\int$  for the

sum, would be equal to the sum of all the work; that is to say, the whole work done in putting the thing together will be written:

$$w = \int f d x.$$

Now, what I want you to think about is this: Here, say, is a coil, and there is a distant core. Though there is a current in the coil it is so far away from the core that practically there is no action; bring them nearer and nearer together; presently they begin to act on one another, there is a pull, which increases as the core enters, then comes to a maximum, then dies away as the end of core begins to protrude at the other side. There is no further pull at all when the two ends stand out equally. Now there has been a certain total amount of work done by this apparatus. Every engineer knows that if we can ascertain the force at every point along the line of travel the work done in that travel is readily expressed by the area of the force curve. Think of the curve,  $x, c, x$ , in fig. 61, the ordinates of which represent the forces. The whole area underneath this curve represents the work done by the system, and therefore represents equally the work you would have to do upon it in pulling the system apart. The area under the curve represents the total work done in attracting in the iron plunger, with a pull distributed over the range  $x, x_1$ .

Now I want you to compare that with the case of an electro-magnet where, instead of having this distributed pull, you have a much stronger pull over a much shorter range. I have endeavoured to contrast the two in the other curves drawn in fig. 61. Suppose we have our coil, and suppose the core, instead of being made of one rod such as this, were made in two parts, so that they could be put together with a screw in the middle, or fastened together in any other mechanical way. Now first treat this rod as a single plunger, screw the two parts together, and begin with the operation of allowing it to enter into the coil, the work done will be the area under the curve which we have already considered. Let us divide the iron core into two. First of all put in one end of it; it will be attracted up in a precisely similar fashion, only being a shorter bar, the maximum would be a little displaced. Let it be drawn in up to half way only; we have now a tube half filled with iron, and in doing so we shall have had a certain amount of work done by the apparatus. As the piece of iron is shorter, the force-curve, which ascends from  $x$  to  $x_1$ , will lie little lower than the curve,  $x, c, x_1$ ; but the area under that lower curve, which stops half way, will be the work done by the attraction of this half core. Now go to the other end and put in the other half of the iron. You now have not only the attraction of the tube, but that of the piece which is already in place, acting like an electro-magnet. Beginning with a gentle attraction, it soon runs up, and draws the force-curve to a tremendously steep peak, becoming a very great force when the distance asunder is very small. We have therefore in this case a totally different curve made up of two parts, a part for the putting in of the first half of the core, and a steeper part for the second; but the net result is, we have the same quantity of iron magnetised in exactly the same manner by the same quantity of electric current running round

the same amount of copper wire—that is to say, the total amount of work done in these two cases is necessarily equal. Whether you allow the entire plunger to come in by a gentle pull over a long range, or whether you put the core in in two pieces—one part with a gentle pull, and the other with a sudden spring up at the end—the total work must be the same; that is to say, the total area under our two new curves must be the same as the area under the old curve. The advantage, then, of this coil-and-plunger method of employing iron and copper is, not that it gets any more work out of the same expenditure of energy, but that it distributes the pull over a considerable range. It does not, however, equalise it altogether over the range of travel.

A number of experimental researches have been made from time to time to elucidate the working of the coil and plunger. Hankel, in 1850, examined the relation between the pull in a given portion of the plunger and the exciting power. He found that, so long as the iron core was so thick and the exciting power so small that magnetisation of the iron never approached saturation, the pull was proportional to the square of the current, and was also proportional to the square of the number of turns of wire. Putting these two facts together we get the rule—which is true only for an unsaturated core in a given position—that the pull is proportional to the square of the ampère turns. This might have been expected, for the magnetism of the iron core will, under the assumptions made above, be proportional to the ampère turns, and the intensity of the magnetic field in which it is placed being also proportional to the ampère turns, the pull, which is the product of the magnetism and of the intensity of the field, ought to be proportional to the square of the ampère turns.

Dub, who examined cores of different thicknesses, found the attraction to vary as the square root of the diameter of the core. His own experiments show that this is inexact, and that the force is quite as nearly proportional to the diameter as to its square root. There is again reason for this. The magnetic circuit consists largely of air-paths by which the magnetic lines flow from one end to the other. As the main part of the magnetic reluctance of the circuit is that of the air, anything which reduces the air reluctance increases the magnetisation, and, consequently, the pull. Now, in this case, the reluctance of the air-paths is mainly governed by the surface exposed by the end portions of the iron core. Increasing these diminishes the reluctance, and increases the magnetisation by a corresponding amount. Von Waltenhofen, in 1870, compared the attraction exerted by two equal (short) tubular coils on two iron cores, one of which was a solid cylindrical rod, and the other a tube of equal length and weight, and found the tube to be more powerfully attracted. Doubtless, the effect of the increased surface in diminishing the reluctance of the magnetic circuit explains the cause of the observation.

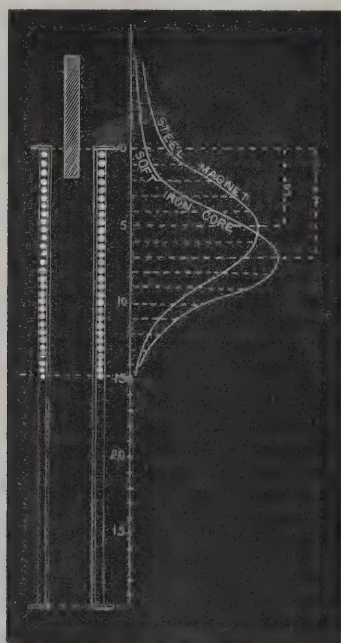

FIG. 62.—VON FEILITZSCH'S EXPERIMENT ON PLUNGERS OF IRON AND STEEL

Von Feilitzsch compared the action of a tubular coil upon a plunger of soft iron with that exerted by the same coil upon a core of hard magnetised steel of equal dimensions. The plungers, fig. 62, were each 10·1 centimetres long; the coil being 29·5 centimetres in length, and 4·2 in diameter. The steel magnet showed a maximum attraction when it had plunged to a depth of 5 centimetres, whilst the iron core had its maximum at a depth of 7 centimetres, doubtless because its own magnetisation went on increasing more than did that of the steel core. As the uniform field region began at a depth of about 8 centimetres, and the cores were 10·1 centimetres in length, one would expect the attracting force to come to zero when the cores had plunged into a depth of about 18 centimetres. As a matter of fact, the zero point was reached a little earlier. It will be noticed that the

pull at the maximum was a little greater in the case of the iron plunger.

The most careful researches of late years are those made by Dr. Theodore Bruger, in 1886. One of his researches, in which a cylindrical iron plunger was used, is represented by two of the curves in fig. 63. He used two coils, one 3½ centimetres long, the other 7 centimetres long. These are indicated in the bottom left-hand corner. The exciting current was a little over 8 ampères.

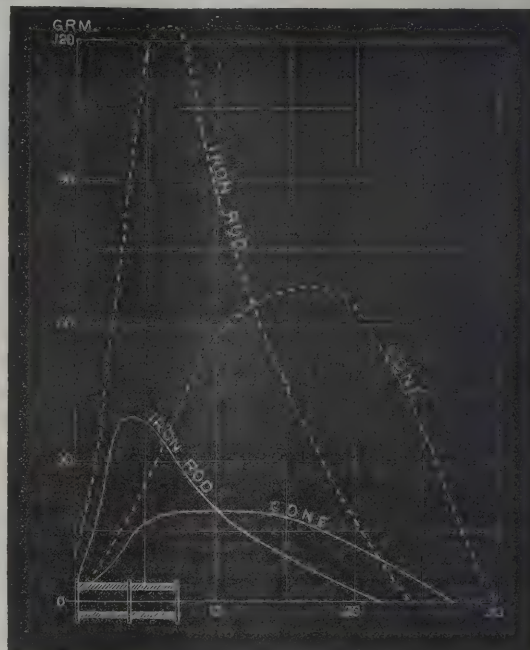

FIG. 63.—BRUGER'S EXPERIMENTS ON COILS AND PLUNGERS.

The cylindrical plunger was 39 centimetres long. The plunger is supposed, in the diagram, to enter on the left, and the number of grammes of pull is plotted out opposite the position of the entering end of the plunger. As the two curves show by their steep peaks

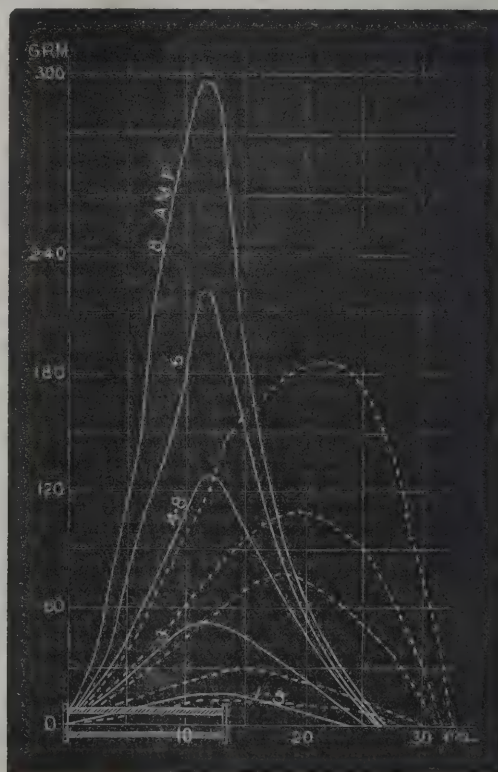

FIG. 64.—BRUGER'S EXPERIMENTS, USING CURRENTS OF VARIOUS STRENGTH.

the maximum pull occurs just when the end of the plunger begins to emerge through the coil: and the pull comes down to zero when the ends of the core protrude equally. In this figure the dotted curves relate to the use of the longer of the two coils. The height of the peak, with the coil of double length, is nearly four times as great, there being double ampère-turns of excitation. In some other experiments, which are plotted in fig. 64, the same core was used with a tubular coil 13 centimetres long. Using currents of various strengths, 1·5 ampère, 3, 4·8, 6, or 8 ampères,

the pull is of course different, but, broadly, you get the same effect, that the maximum pull occurs just where the pole begins to come out at the far end of the tubular coil. There are slight differences; with the smallest amount of current the maximum is exactly over the end of the tube, but with currents rather larger, the maximum point comes a little farther back. When the core gets well saturated, the force curve does not go on rising so far; it begins to turn over at an earlier stage, and the maximum place is necessarily displaced a little way back from the end of the tube. That was also observed by Von Waltenhofen when using the steel magnet.

(To be continued.)

## LONDON COUNTY COUNCIL.

THE weekly meeting was held on Tuesday at Spring Gardens, S.W., Sir John Lubbock in the chair. The Highways Committee reported the following:

The council on the 30th of September last sanctioned the continued employment for three months in the engineer's department of a person, at a salary of £3 3s. a week, who has been since 25th February last assisting with the work connected with the business of which your committee has charge. The time referred to has now elapsed; but the chief engineer has informed us that the assistance it still required. We propose to report again on this matter after the Christmas vacation; and in the meantime we recommend: That the services of the temporary assistant now employed at a salary of £3 3s. a week in the engineer's department, be retained until the second meeting of the council in January next.

We have considered a letter from the London Electric Supply Corporation, asking that in the case of the service lines from distributing mains the one month's notice specified in the company's order may not be insisted upon, and that a shorter notice may be accepted. The company states that the Postmaster-General has agreed to accept a 48 hours' notice, and asks that the council will do the same. We are of opinion that, although in the case of the laying of service lines, the one month's notice is not necessary, the 48 hours' notice proposed by the company is on the other hand insufficient, and that at least four days' notice should be given by the company. We therefore recommend:—

That the London Electric Supply Corporation be informed with reference to the laying of service lines from distributing mains already laid, that the council will, until it gives notice to the contrary, accept four days' notice, instead of the one month's notice, required by the company's order.

We have considered a notice (Registered No. 139), dated 5th December, 1890, from the vestry of St. Pancras, of electric lighting works proposed to be carried out by the vestry in certain streets in the parish, under the provisions of the St. Pancras (Middlesex) Electric Lighting Order, 1883, as shown upon three plans and six drawings submitted with the application. The details shown are generally satisfactory, but if any high tension mains are to be used, some precautions appear to be necessary for the prevention of accidents. We recommend—

That the council do approve the works referred to in the notice (Registered No. 139), of the vestry of St. Pancras, dated 5th December, 1890, under the provisions of the St. Pancras (Middlesex) Electric Lighting Order, 1883; and that it be suggested to the vestry that where any high tension mains are used the frames and the cover of the boxes through which the mains pass should be carefully earthed.

The Kensington and Knightsbridge Electric Lighting Company has given a notice (Registered No. 140), dated 27th November, 1890, of a proposed extension of mains in Alfred Place West (1 plan). The works are of the usual description; and we recommend—

That the consent of the council be given to the works referred to in the notice (Registered No. 140) of the Kensington and Knightsbridge Electric Lighting Company, Dated 27th November, 1890.

A notice, dated 2nd December, 1890 (Registered No. 141), has been given by the Metropolitan Electric Lighting Company of intention to lay mains in Northumberland Avenue, from the Hotel Victoria to Whitehall, and thence along Whitehall and Whitehall Place to the company's station in Whitehall Court (1 plan). These works are of the same description as those of this company already sanctioned; and although there is a subway in Northumberland Avenue, we think it unnecessary that the company should be required to lay in the subway the very short length of main for that thoroughfare included in the notice. We recommend:—

That the sanction of the council be given to the works referred to in the notice (Registered No. 141), dated 2nd December, 1890, of the Metropolitan Electric Supply Company, upon condition that the company do give two days' notice to the council's chief engineer before commencing the works; that the mains be enclosed in 5-inch iron pipe and be laid under the footways wherever it is found practicable to do so; that the covers of the boxes to be used shall consist of iron frames filled in with material to suit the paving; and that the works generally shall be of the character approved by the council on 1st October, 1889.

The London Electric Supply Corporation has served three notices (Registered Nos. 142, 143 and 144), one dated 25th November, and two 2nd December, 1890, under section 19 of the com-

pany's order of 1889, of works executed on emergency, in laying service lines to No. 15, Clifford Street, Bond Street, and to Nos. 14 and 42, Curzon Street. There is no reason for objecting to these works; and we report for the information of the council the receipt of the notices with regard to them.

## ELECTRIC LIGHTING PROGRESS IN LONDON.\*

By F. BAILEY, Assoc. M. Inst. C.E.

THE last paper on electric lighting read before the Society was by Mr. R. E. B. Crompton, in 1888, when he placed before you some of the difficulties and obstacles which were retarding the progress of electric lighting. The rapid progress made within the last 18 months will, however, show that these difficulties have, to a great extent, been removed by a number of supply companies having obtained Parliamentary powers to lay mains within certain specified areas into which London has been divided. I propose, therefore, to place before you, in general terms, the work done and in progress by the various companies, as the time at my disposal will not permit me to give minute details of generating stations and systems.

Through the kindness of Mr. J. W. Swan, I have the honour to show you the first lamp he made. It is to be hoped that this lamp will eventually come under the care of one of our great museums, in order that future ages may recognise the genius of Mr. Swan.

I have also to thank Mr. Sydney Morse for the loan of another valuable historical lamp, this being the first lamp constructed by Edison.

Turning to the record of general distribution of the electric light in London, you all know that practically nothing was done under the Act of 1882, but private enterprise provided fields for encouraging the efforts of the electrical engineer, and foremost amongst these must be mentioned the Grosvenor Gallery station, which did such good service in making the capabilities of the light known, and in proving the absolute necessity that existed for it; for however defective the supply may have been towards the close of the existence of the station (owing to the plant being overloaded), we owe a debt of gratitude to Lord Crawford for his energetic support to this enterprise, and to those who worked so hard to bring it to perfection. Mr. Ferranti, and those who worked with him at the Grosvenor, laid the foundation stone of a satisfactory transformer system, and as they had no Parliamentary powers to lay down underground mains, overhead lines were run in all directions. The perfection to which they brought the details of overhead construction is so fully proved by the absence of accidents, that it is much to be regretted that the overhead conductors in the United States were allowed to have been put up with no regard to common sense or safety.

It is frequently stated that the Electric Lighting Act of 1882 did much towards stifling inordinate speculation, but in attempting to make people wise by this Act of Parliament, a very serious check was placed upon the development of electrical progress.

The enormous strides which have been made under the more encouraging Electric Lighting Act of 1888 will convince everyone that it was urgently required, and electrical engineers fully realise what they owe to Sir Frederick Bramwell for his share in framing this Act. One of the consequences of this Act was a deluge of applications for provisional orders. A court of enquiry was therefore ordered by the Board of Trade, who appointed Major Marindin as their inspector for this purpose.

If you carefully read the 18 days' evidence given, you will probably be convinced that every system was the best. The inquiry lasted several days, and resulted in the granting of provisional orders, confirmed by Parliament in August, 1889, to the companies mentioned in the summary on page 54, which also includes other information.

I must here gratefully acknowledge the very cordial assistance which the engineers of the various companies have given me.

We will now very briefly go round the stations of the companies, commencing with

### *The Kensington and Knightsbridge Electric Light Company.*

This company commenced work under the name of the Kensington Court Electric Light Company in the autumn of 1886, and under Mr. Crompton's able guidance made such rapid progress that they commenced to supply current in January, 1887, using underground mains and running their plant in a temporary building. The Board of Trade license under which the work commenced, is incorporated in the company's provisional order of 1889, which authorises them to supply a portion of the parish of Kensington, St. Mary Abbot, and the detached portion of the parish of St. Margaret, Westminster.

The direct current is employed in conjunction with "Howell" secondary batteries, the pressure being 200 volts on the 3-wire system, with 100 volts in the houses.

The satisfactory use of secondary batteries in this manner has attained its present development mainly through the indefatigable labours of Mr. J. C. Howell.

Two generating stations are erected, one at Kensington Court, and the other at Chapel Place, Knightsbridge, the plant consisting of "Babcock and Wilcox" boilers and exhaust steam feed

\* Read before the Society of Arts, Wednesday, December 10th.

water heaters, "Willans's" compound engines combined direct with Crompton dynamos and "Howell" batteries in both stations. There is also a battery station situated near the centre of the Kensington district at Queen's Terrace Mews, where two large "Howell" batteries are placed. In all cases ample space is provided for the future extension of the plant when required. Arrangements are provided on the Kensington Court station switchboards to enable any dynamo to be used for charging the distant battery station, to which a pair of charging mains are laid, Mr. Crompton also designed for this company a system of mains of considerable novelty, which was severely criticised at the time, but has since proved most satisfactory.

Culverts constructed with concrete or brickwork are laid under the pavements, and bare copper conductors, supported at intervals by glass insulators, are placed in these culverts. The conductors are composed of copper strips  $1\frac{1}{2}$  by  $\frac{1}{4}$  inch, laid one over the other, so as to make up the total section required. In cases where there is no room under the pavement in which to build up the culvert, wrought-iron gas tubing is used, and cables insulated with thick vulcanised rubber are drawn through and connected to the bare conductors. Numerous service boxes are fixed in the pavements to enable houses to be connected without opening the ground. Four and a half miles of pipes with cables have been laid.

On the 1st December, lamps were connected to an equivalent of 24,850 32-watt lamps, and Mr. H. W. Miller, the company's engineer, to whom I am indebted for these particulars, informs me that the lamp supply, or maximum number of lamps in use at one moment, is between 30-40 per cent. of the lamp connection.

#### *The House-to-House Electric Light Supply Company.*

This company covers a large area, which consists of two detached districts, practically North Kensington and West Brompton. The generating station is situated off the Richmond Road, West Brompton, and contains space for a very large plant.

The Lowrie-Hall alternating current transformer system is adopted, with 2,000 volts on the mains. Four principal mains at present carry the current from the station, the transformers being connected to these mains where required. Cast-iron pipes are laid to form a conduit into which vulcanised india-rubber "Silver-town" cables are drawn; suitable manholes, covers, and junction-boxes being provided.

At present the demand for light is supplied from a plant, consisting of:—

Three "Babcock and Wilcox" boilers, working at 150 lbs. per square inch.

Three "Fowler" compound horizontal engines, each of 200 indicated horse-power.

Three "Lowrie-Hall" alternators, each of 100 units 2,000 volts.

Three "Elwell-Parker" exciters, each of 3 units.

The engines work at a speed of 88 revolutions per minute, each engine driving one alternator by seven cotton ropes, the exciter for each alternator being driven by cotton ropes from the alternator pulley.

The Lowrie-Hall pressure regulator and recording instruments are also used. Mr. Hall, the company's manager, has kindly given me this information, and states that on their lamp connections, equivalent to 12,898 lamps of 8 candle-power, the maximum lamp supply is equivalent to 5,430 lamps of 8 candle-power—say, 42 per cent.

#### *St. James and Pall Mall Electric Lighting Company.*

This company was formed for the purpose of supplying the whole of the parish of St. James's, Westminster, and commenced to supply current under their provisional orders from their station in Mason's Yard, Duke Street, on April 4th, 1889.

The direct current is employed without batteries. At present the above station supplies the southern half of the district, the total plant consisting of:—

Five "Davey-Paxman" boilers, working at 150 lbs. per square inch.

Two large Berryman feed water heaters.

Ten Willans's compound engines, each of 200 indicated horse-power.

Two Willans's compound engines, each of 80 indicated horse-power.

Twelve dynamos, "Latimer Clark, Muirhead & Co.," and "Siemens," driven direct from the engines.

The whole of this plant is neatly arranged, so as to occupy the least space.

The mains consist of a network of conductors on the three-wire system, supplied at about 100 volts at the station by suitable feeders. A cast iron trough or culvert is laid under the surface of the pavement, and three conductors, each consisting of a number of strips of bare copper, which can be added to at any time, are carried by porcelain bridges, placed at suitable intervals apart. To avoid any risk of the mains touching each other, porcelain distance pieces are placed over the mains. A cast iron lid, with water-tight joint, covers the trough. Connection to customers' houses is made by drawing well-insulated cable through gas tubing, which is screwed into the trough.

On the 5th December, a total, equivalent to 23,174 lamps of 8 candle-power, were connected. Mr. Dolson, the company's engineer, kindly informed me that the maximum lamp supply is equal to about 13,222 lamps of 8 candle-power—say 57 per cent.

#### *The Westminster Electric Supply Corporation, Limited.*

The district in which this corporation is authorised to supply electricity by its provisional order comprises that portion of the united parishes of St. Margaret and St. John, Westminster, which lies to the south of the centre line of the Metropolitan District Railway, and the portion of the St. George, Hanover Square, covering Belgravia and Mayfair.

The system adopted is similar to that of the Kensington and Knightsbridge Company, direct current in conjunction with batteries used as regulators, and also for supply during hours of minimum demand.

Three stations are being erected, one at Millbank Street, one at Eccleston Place, and one in Davies Street.

Current is now being supplied from the Millbank Street station and from a small temporary station in Dacre Street. The other two are being pushed forward as fast as possible, in order to supply from all stations early in the year.

Mains are being laid for a three-wire distribution, Messrs. Crompton being the contractors for the Westminster district, where the system adopted is similar to that put down by Mr. Crompton for the Kensington and Knightsbridge Company.

For other parts of the district Prof. Kennedy, the engineer to the company, has devised the following arrangement: bare copper strip rests on stoneware insulators placed from 6 to 8 feet apart, and bedded in the concrete culvert. The copper is stretched by a special tool before being pulled in, and this process gives it sufficient stiffness not to sag perceptibly between the insulators. The total sectional area of the conductors can be increased when required by the addition of more copper strip. Feeders are used in a most systematic manner, and Prof. Kennedy is to be congratulated on the favourable prospects of this company's work. There is a large demand for light in the district, and the rapid progress of this company justified the expectation of a speedy supply from the stations now in progress.

#### *The London Electric Supply Corporation, Limited.*

The Parliamentary powers possessed by this company cover a large area, comprising the district bordering the south side of the Thames from Westminster Bridge to Greenwich, Mayfair, Belgravia, St. James's and Pall Mall, St. Martin's-in-the-Fields, part of Westminster, Chelsea, and two isolated areas, namely, Newington and Clerkenwell.

The Ferranti system is employed throughout, alternating current being generated at an extra high pressure and transmitted to converting stations, from which it is distributed at high pressure to the service converters.

The corporation has erected a large station at Deptford, which has been admirably designed for the purpose, having road frontage, wharfage, and coaling dock. The plant consists of 24 "Babcock and Wilcox" boilers, four compound vertical engines by Hick Hargreaves & Co., two of which are 1,500 indicated horse-power each, and two of 750 indicated horse-power each. There is almost unlimited room for future extension.

Each of these engines drives a Ferranti dynamo by cotton ropes, the exciters being driven direct from independent engines.

In order to convey the high pressure from Deptford to London, Mr. Ferranti devised a special form of main for this purpose, which has been frequently described.

About 28 miles of these mains have been laid, the distributing mains from the converting stations being of various kinds. This company's Grosvenor Gallery station having lately been closed, a hurried change has had to be made in order to enable the corporation to supply from Deptford.

#### *Chelsea Electricity Supply Company.*

This company's provisional order covers the whole parish of Chelsea, a portion of which the company is now supplying.

Direct current is employed with accumulators, but, unlike the other companies in London, in this case the accumulators are charged with a high pressure current, and discharge direct at low pressure into the mains. I am not in possession of any information of this company's progress. From published descriptions you will doubtless be aware that the generating station is situated at Draycot Place, with battery stations at Clabon Mews, Egerton Mews, and Pavilion Road.

#### *The Electricity Supply Corporation.*

This company obtained a provisional order in 1889 for supplying the whole of the parish of St. Martin's-in-the-Fields. Direct current, without batteries. The station is placed just off the Strand, and was laid down some years ago by Messrs. Gatti, to supply the Adelaide Gallery and the Adelphi Theatre; it is now being extended. At present the plant consists of:—

Four "Babcock and Wilcox" boilers.

Five Willans's engines, amounting to 600 indicated horse-power.

Five "Edison-Hopkinson" dynamos, each being driven direct from one engine. Callender mains are laid down in Callender-Webber casing.

#### *St. Pancras Vestry.*

The vestry have decided to carry out the electric lighting of the parish themselves, and have secured the able services of Prof. Robinson as their engineer. The direct current system will be adopted, and a station is now being erected in Stanhope Street, Euston Road, for the supply of the south-west portion of the parish.

*Notting Hill Electric Lighting Company.*

The provisional order granted to this company includes the district of Notting Hill, which comes within part of the parish of Kensington, St. Mary Abbot.

The system is similar to that adopted by the Kensington and Knightsbridge Company.

The first generating station, situated off High Street, Kensington, is now approaching completion, the plant consisting of Babcock and Wilcox boilers, Willans's engines, Crompton dynamos, and Howell batteries; Crompton's mains are also laid.

*The Metropolitan Electric Supply Company.*

The Parliamentary powers of this company include the large and important districts of Paddington and Marylebone parishes, with part of St. Martin's-in-the-Fields, the Holborn and Strand district, and St. Giles's Board of Works.

Various systems are employed by this company, both the alternating and direct current systems being adopted.

The company is at present supplying from four stations, and it may perhaps be better to describe them separately.

The Whitehall station, situated in Whitehall Avenue, is a direct current station which possesses no novelty, and supplies the surrounding locality, the plant consisting of Hick Hargreaves' boilers, Willans's engines, and Siemens' dynamos. Callender mains are laid down the Northumberland Avenue Subway and elsewhere.

The Sardinia Street station contains a complete plant on the Westinghouse alternating current system, consisting of twelve Babcock and Wilcox boilers, working at 150 lbs. per square inch; twelve Westinghouse alternators, each being belt-driven by a Westinghouse compound engine. There are also three exciters, each being belt-driven by its own engine.

The Manchester Square station contains nine Babcock and Wilcox boilers, ten Parker alternators, each driven direct by a 200 horse-power Willans's engine. There are also four exciters, each being driven direct by a Willans's engine. The steam piping is arranged on a method devised by Mr. J. H. Rosenthal, the London manager of the Babcock and Wilcox Boiler Company, and possesses many advantages.

The Rathbone Place station contains plant of a similar kind, there being five boilers, six alternators and engines, two exciters and engines.

The system of distribution from the three latter alternating current stations is of a simple description—cast-iron pipes laid underground form conduits, into which "Silvertown" vulcanised rubber cables have been drawn when required. Split T-pieces are inserted in the pipes for connection to customers' premises. These mains are looped from house-to-house, returning to the station, so as to form complete rings. Each customer has, therefore, a duplicate supply, thus enabling new customers to be connected to the system without interrupting the supply on the circuit.

All these three stations are connected together by trunk mains, which enable one station to assist another, or take the whole load of the district during the hours of least demand. The current leaves each of these stations at a pressure of 1,000 volts, this moderate pressure being adopted as the number of supply stations reduces the distance to which each cable has to be laid to meet the demand. The whole supply is distributed by a number of small cables, which can be easily replaced when required.

The demand for light has been very encouraging; and, as you will see from the table,\* the progress of the lamp connection to these stations has been very rapid. I regret, however, to say that, although this company at present supplies light to 12 public-houses, only four churches are, so far, connected with the system.

Having now completed our tour of the stations of the various companies, we have seen how the streets of London have lately been disturbed in order to lay all these mains; no doubt a certain amount of inconvenience has unavoidably been caused to traffic, but it has revealed the wonderful system of organisation by which London is governed; and the vestry surveyors, whose labours have been much increased, have not only afforded every facility for carrying out the work, but have rapidly re-instated the pavements at, of course, the cost of the respective electric light companies. The public, therefore, though for a short time inconvenienced, have in reality secured new pavements for old.

Summarising the plants adopted by the various supply companies, it is interesting to notice how the peculiar conditions of electrical supply in the very limited space usually available have been provided for by manufacturers. As an instance of this, it may be noted that "Willans's" engines, amounting to about 9,000 horse-power, are used by the public supply companies in London; and similar engines, aggregating more than 2,000 indicated horse-power, for private plants in the metropolis. The Babcock and Wilcox boiler having also been so universally adopted, it may be of interest to state that 78 boilers of this type, supplying 14,230 indicated horse-power, are now at work in London.

*Private Plants.*

One result of the Act of 1882 has undoubtedly been to cause a large number of private installations to be erected, but so many of our leading electric light contractors have laid down thoroughly efficient plants that there is perhaps no cause for regret. Most of

the large terminal London railway stations work their own electric light machinery, the largest installation being at Paddington, where the Great Western Railway Company have machinery of 1,500 horse-power for this purpose. For residences, gas-engines provide the motive power for driving dynamos supplying about 18,000 lamps of 32 watts each, the remainder being steam-driven.

It may be of interest to note that the Crossley "Otto" gas engine, which was awarded a gold medal at this Society's recent motor competition, is being employed for this purpose, amongst others, by Messrs. Laing, Wharton and Down. This total may appear large, but it must be remembered that many of the large hotels having their own steam plant for working lifts, warming and cooking, have added electric lighting machinery; the total also includes the lamps at D'Oyly Carte's new theatre, where Messrs. Verity have erected a plant so complete, that it may almost be considered as a small central station.

*Number of Incandescent Lamps now in Use in London.*

With the kind assistance of the electric light contractors, particularly Messrs. Verity, Laing, Wharton and Down, Phipps and Dawson, Drake and Gorham, Sharp and Kent, and many others, and the public supply companies, I have been able to collect data that the total equivalent number of 32 watt lamps now in use in London is approximately as follows:—

Public supply companies	179,060
Private plants	85,000
Total	264,060

At the present rate of increase, a very moderate estimate gives an addition of at least 4,000 lamps per week, and there is little doubt that this number will be greatly exceeded at no distant date.

All these incandescent lamps have been calculated on a basis of 32 watts or 8 candle-power lamps, as experience has shown that this is a size much used in London, and, by taking the smallest lamp, we avoid dealing with half lamps.

Before leaving these particulars, it will probably be of service to the designers of future stations if we tabulate the data collected.

*Table Showing Percentage of Maximum Lamp Supply at any Moment to Total Lamp Connection.*

Station.	Percentage.
House-to-House	42
Kensington and Knightsbridge	30 to 40
St. James's and Pall Mall	57
Sardinia Street	45
Rathbone Place	64
Manchester Square	45

It perhaps may be of interest if I draw your attention to the following table, based upon data which has come under my observation, showing the candle-power of lamps mostly used:—

<i>Lamps (50 Volts).</i>						
8 C.P.	16 C.P.	32 C.P.	60 C.P.	100 C.P.	200 C.P.	500 C.P.
597	1,666	62	13	8	8	3
<i>Lamps (100 Volts)</i>						
5,437	5,131	176	26	57	40	3

During 1886 and part of 1887 I was able to collect the following data of the behaviour of incandescent lamps, each of 25 candle-power, with an efficiency of  $3\frac{1}{2}$  watts per candle, and I trust that more information of this kind will be collected.

With reference to arc lighting, considerable progress is being made; and, although the number now in use in London does not much exceed 1,000 lamps, there is no doubt that rapid progress will be made.

Prof. Silvanus Thompson, in March, 1889, showed you all the best known arc lamps; and, for further information of their development, I must refer you to his most complete paper on this subject, published in the Society's *Journal*, March 8th, 1889.

It is a matter for regret that there is no progress to be noticed in connection with the efficiency of the incandescent lamp, which remains much the same as it was five years ago. It will be apparent from the table showing the candle-power of lamps mostly used, that a really efficient 100-volt 8 candle-power lamp is much needed; the present lamps of this kind have such a short life that customers, contractors, and electric supply companies would all hail its advent as a boon.

We must also remember that the future progress of electric lighting depends in no small measure on the lamp-makers, and as the manufacture of the incandescent lamp will soon be open to all (owing to the expiration of the present patents), the absolute necessity of a standardising laboratory must compel its adoption where not only instruments but lamps can be tested, so that people may know when they ask for an 8 candle-power 100-volt lamp, with or without a guaranteed life of, say, 1,000 hours' at an efficiency of  $3\frac{1}{2}$  watts per candle, that they get what they have asked for.

That this question of lamp efficiency is of importance to cus-

\* This table, giving particulars of the Electric Light Companies of London, we published last week as a special page.—EDS. ELEC. REV.

INCANDESCENT LAMPS.—LIFE AND NATURE OF FRACTURE.

All Lamps 25 C.P. Brass Collar, Edison-Swan.

Lamps.			Nature of failure.											
Volts.	No. of lamps renewed.	Average life hours.	Glass globe.						Filament fractured.					
			Broken.	Per cent.	Blackened.	Per cent.	Plaster.	Per cent.	Loop.	Per cent.	Stem.	Per cent.	Joint.	Per cent.
151	536	861	114	21·2	21	3·91	56	10·44	208	38·80	114	21·26	23	4·29
142	189	789	19	10·0	4	2·11	41	21·69	67	35·45	47	24·96	11	5·82
120	2,549	923	273	10·7	92	3·60	334	13·1	1,114	43·70	693	27·10	43	1·68
99	588	1,423	122	20·7	61	10·37	92	15·64	212	36·00	95	16·10	6	1·02
	3,862		528		178		523		1,601		949		83	
				13·67		4·61		13·54		41·46		24·57		2·15

tomers and supply companies alike few will doubt, and the following Table will probably explain itself :—

Watts per candle.	Candles per 1,000 watts.	Lamps per 1,000 watts.			
		8 C.P.	16 C.P.	20 C.P.	32 C.P.
2·00	500·0	62·5	31·2	25·0	15·6
2·25	444·5	55·5	27·7	22·2	13·9
2·50	400·0	50·0	25·0	20·0	12·5
2·75	363·6	45·4	22·7	18·2	11·4
3·00	333·3	41·7	20·8	16·7	10·4
3·25	307·6	38·4	19·2	15·4	9·6
3·50	285·7	35·7	17·8	14·3	8·9
3·75	266·6	33·3	16·7	13·3	8·3
4·00	250·0	31·2	15·6	12·5	7·8

We see, then, how an improved lamp efficiency will benefit the supply companies, by enabling them to increase their lamp connection.

The following Table will appeal most strongly to all users of the incandescent lamp; but it must be assumed that an increased efficiency is not obtained at the expense of a reduced life of the lamps.

The most satisfactory feature, however, of the present Edison-Swan lamps is the uniformity of their voltage; and the scientific department of the Edison and Swan Company's work is to be congratulated on the assistance they have given to the industry, by practically enabling voltmeters to be set by photometrical tests of the lamps.

Cost per Annum per 8 Candle-power lamp at 8d. per Unit, Lamps Burning an Average of :—

Per day.	1 hour per day.	1 hour per day.	2 hours per day.	3 hours per day.	4 hours per day.
Hours per Annum.	182·5	365	730	1,095	1,460

Cost per annum with lamp efficiency of :—

	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.
2 watts per candle	0 1 11	0 3 11	0 7 10	0 11 9	0 15 8
2·25	0 2 20	0 4 50	0 8 90	0 13 20	0 17 6
2·50	0 2 50	0 4 100	0 9 90	0 14 70	0 19 6
2·75	0 2 80	0 5 40	0 10 90	0 16 11	0 1 5
3·00	0 2 110	0 5 100	0 11 80	0 17 61	0 3 4
3·25	0 3 20	0 6 40	0 12 80	0 19 01	0 5 4
3·50	0 3 50	0 6 100	0 13 81	0 21 7	0 7 3
3·75	0 3 80	0 7 40	0 14 71	0 23 11	0 9 2
4·00	0 3 110	0 7 100	0 15 81	0 25 61	0 11 4

It may be thought that an estimated use of a lamp for only about 200 or 300 hours per annum is very low, but it should be remembered that the electric light need only be used when it is required, as the ease of switching it on and off makes us forget all our past troubles in hunting for gas-taps, matches, and broken gas globes. With ordinary care, the average cost of burning an 8 candle-power lamp for ordinary domestic use need not exceed ten shillings per annum.

Of course much depends on the wiring contractor, who not only has to be an accomplished art critic in designing or selecting the brackets, pendants, &c., but he has also to select the most advantageous positions for the lamps and switches. A switch placed near the door of every room, and not less than two lamps in any room, will probably save annoyance.

The greatest progress has been made in the wiring of houses,

Not only is more work done, but it is better done, and on more mechanical principles, for whereas some years ago a single main would have been run from top to bottom of a house with numerous T-joints, independent circuits will now be wired, and all brought to a neat form of distributing board.

The effect of the extra care which is now taken with this work is proved by the following table of insulation tests, taken with 100 volts at 200 houses :—

Insulation Tests of Internal Wiring (Taken with 100 Volts—Evershed Ohmmeter.

Number of points.		Test megohms.
5 to 10	Average of 15 houses	4·0
10 " 15	" 23 "	3·5
15 " 20	" 18 "	2·8

I hoped to have been able to place before you some record of the improvement in the health of London, owing to the progress of electric lighting, but so much has already been said and published about it that further facts appear needless. It is simply melancholy to see so many of our churches and halls not only burning their gas jets for lighting, but also for "warming" the building. If culpable negligence amounts to manslaughter, the people responsible for this atrocity ought to receive their deserts.

Having now placed before you some account of the progress of electric lighting in London, I must ask you to compare our metropolis with other cities, and leave you to judge whether we are so very far behind them as some would have us believe. Is it not more probable that other countries will be glad to avail themselves of the experience which London must gain in the working of so many distinct systems?

DISCUSSION.

Mr. E. E. CROMPTON said that electric engineers might feel proud that, although they had been so heavily handicapped in the race, they had begun at last to bring London to the front, and it would not be long before they were as far ahead of any other town in the world in electric lighting as they were in most other respects. The Act of 1882 completely stopped electric lighting for several years, though, as engineer to the Edison and Swan Company, he then designed several central stations which, even in the light of present knowledge, he could say could have been carried out practically as well then as they could now. Five years ago a gentleman called at his office and said he was connected with an estate company which had a subway, so that underground mains could be laid without coming under the Act, and the result was the formation of the Kensington Court Company, his informant being Mr. Granville Ryder, the present chairman of the company. At that time not a single underground main had been tried, and but for this opportunity of testing the system, it was very improbable that either the Kensington Court Company, the Whitehall, or the Metropolitan Company would have occupied the positions they now did. The results then obtained led to the agitation which produced the amended Act. The public should know that though they might have been inconvenienced by the breaking up of the streets, it was a very different thing from similar annoyances on the part of gas and water companies, because in most cases the work was done once for all.

Conduits or pipes had been laid, into which the conductors could be drawn, and from which they could be withdrawn and repaired, so that connections could be made without further breaking up of the road. He did not know the exact mileage, but he should think nearly 150 miles had already been laid, which was no small feat to accomplish since the provisional orders were obtained two years ago. In the system of underground conductors with which Mr. Bailey had connected his name—though he was by no means the sole inventor, many other engineers having contributed to its development—the idea was not only to give access to every house for the electric light, but to afford sufficient means of access for many other systems of conductors in future—telephone wires, fire alarms, and other means of communication, which would be greatly appreciated in future, and though the idea might now seem Utopian, he hoped the time would come when compressed air might also be supplied for the purpose of giving cool storage in every larder.

Prof. KENNEDY, F.R.S., said this paper would be much quoted after a few years, for Mr. Bailey had given a most vivid picture of the state of electric lighting in London, just at the time when it was most interesting. As to the maximum number of lights at one time in use as compared to the total number on the station, he had been apparently very fortunate in one of his own districts. He had found in Westminster the usual average was about 40 to 42 per cent., but one foggy day in last week it went up to 60 or 61, judging from the amount of current going out. As to the state of electric lighting in London compared with other places, there was no other city in the world that had 250,000 lights, or anything like it. He believed it was about double the amount in use in New York, and before long people would be coming here for information, instead of scoffing at us for doing nothing. With regard to safety in working the station, he thought that there should always be power in reserve equal to one of the largest units; if 200 horse-power engines were the largest used, for instance, there would be 200 horse-power in reserve, but the use of one 500 horse-power engine necessitated at least 500 horse-power in reserve, and so on. He should be glad to think that putting a boiler on a lower level than the engine would ensure having dry steam, but rather doubted whether that was proved experimentally. If the particular boilers mentioned gave dry steam, he did not think it could be owing to their position in reference to the engine.

Prof. FORBES, F.R.S., asked what the black spider-like lines on the map indicated? Mr. Bailey had collected an enormous number of the very facts engineers wanted to arrive at, and he hoped other gentlemen connected with central stations would follow his example and give the result of their experience. Mr. Bailey seemed rather hurt because various people had criticised the progress of electric lighting in this country, and contrasted it unfavourably with what was done elsewhere, and perhaps few had done more in that way than he (Prof. Forbes) had. He had taken the pains to learn what was being done in foreign countries by personal inspection, and had frequently, on his return from such enquiries, done his best to impress on those concerned at home the superiority of the work that was being done abroad. The last time he had occasion to do so was about three years ago, when hardly any of the work now described had been commenced; but he now thoroughly endorsed what had been said by Prof. Kennedy, that there was not an example in the whole world of such enormous progress in so short a time. They were delayed for a long time by the former Act, but during all that time they were studying what was done elsewhere, so that when they began they were on sure ground, and went ahead with more confidence than people elsewhere had done. Not only was the scale of work greater in London than anywhere else, but the character of the work in the central stations would bear comparison with any. Any one who had visited the Sardinia Street station would feel that it was as complete and satisfactory as it could possibly be.

Mr. W. M. MORDEY said that he believed this paper would be of the greatest value. He suggested that it should be followed, at fairly frequent intervals, with other accounts of the work that was actually being done. He remarked that Mr. Bailey's particular arrangement of primary mains, which was very simple and ingenious, had not been alluded to in the paper. It would be very useful if they could have not only the relative life of 50 and 100-volt lamps, but their relative efficiency. It would be well to know how much the lowering of the candle-power of the former counter-balanced the advantage of the longer life, the blackening of the globe in a low voltage lamp being always more serious than in the case of a high one. A strong confirmation of what had fallen from the Chairman and Mr. Crompton as to the effect of the Act of 1882 was to be found in experience abroad. It was often stated that our knowledge of how to distribute electricity had greatly advanced since 1882. This was true, but it was also true that, so far as supplying lights in a densely inhabited district was concerned, no great advance had been made or was to be expected. As an illustration of this, he referred to Milan, where a large scheme had been carried out on the lines that were available in 1882. Just about 1883, a station was put down there which had never had the current off the mains for six years, and it was now supplying 25,000 16-candle-power lamps, on the direct low-tension system. The history of that station showed that, in a dense area, the old-fashioned system was very good in its way, even without the advantage of the three-wire arrangement. Distant places—suburbs, and so on—could not be supplied, but they were now supplying the more distant parts on the high-tension system, somewhat similar to that mainly used by Mr. Bailey's company. The history of the Metropolitan Company illustrated the advance

in knowledge of how to distribute light over a large area economically, especially in the early stages of the work. That company started with a low-tension system and with batteries; but all the stations added since were on the high-tension system, without batteries. They knew now how to supply both in dense areas and over long distances. Mr. Crompton had, in London, perhaps done more than any one in the former direction, and the Metropolitan Company more than any one—except, perhaps, Mr. Ferranti—in the latter. A great deal had been said by Mr. Preece and others in that room on the advantage of lighting streets by arc lamps. It appeared that there were only about 1,000 in use in London altogether. He thought the general public would never fully appreciate the advantages of electric lighting until the whole of the main streets were illuminated in that way. Nothing had been said about the electric lighting of the City, no doubt for the reason that there was at present no lighting in the City. This reproach would shortly be removed, his company and others having undertaken a general lighting scheme, which, he was glad to say, included street lighting by arc lamps.

Mr. R. W. WALLACE pointed out the great importance of endeavouring to improve incandescent lamps. He believed, from some experiments which had been made, that it would be possible to reduce the amount of current used in these lamps by about one-third, though the result might be to shorten the life of the lamp. But when one considered the value of the lamp compared with the price of the current for a number of hours, that would be but a small matter. He hoped, therefore, that inventors would turn their attention in this direction.

Mr. CHAPLIN said it would be very interesting to know if there were any data showing whether an incandescent lamp worked with a low-tension current had a much longer life than one worked with a high-tension.

Mr. BAILEY, in reply, said that so far as he could ascertain there were now 81½ miles of conduits of all kinds, in some cases pipes, in others concrete or brickwork; and into these conduits were led about 111½ miles of cable, which were actually carrying current at the present moment; and that had practically been accomplished in 18 months, in order to supply the public with electric lighting, but they had not yet got to street lighting. That brought him to the question of arc lamps. Everyone would like to see arc lighting, but they could never expect to see it in London in such perfection as in Milan and other places where the streets were practically built for it. One could not imagine the Strand looking particularly handsome, even with the aid of arc lamps; it was quite different in Berlin, where they could be placed in the centre of the roadway on very high masts; but such as the streets of London were, they would be immensely improved by arc lighting, and he believed this would come shortly; and in place of the very meagre account of this system which he had been able to give, he hoped before long to hear someone else give a much more ample description of what was being done in this way. Everything was now ready for it, and he could not quite understand what kept it back. Prof. Kennedy had referred to the maximum percentage of supply to the total lamp connection, as to which you might take either the average or the heaviest day, the figures given in the paper being the heaviest lighting day in November; and he found that in all the districts from which he had collected information that the heaviest duty came on between four and five in the afternoon. (He exhibited a number of diagrams showing the varying amounts of current demanded during the day, plotted on a curve, taken at different stations and on different days, the highest point varying according as the district consisted mainly of offices, shops, or theatres and restaurants.) The black spider-like lines which Prof. Forbes referred to, showed overhead wires, and he desired to emphasise what he had said in the paper on this point. There were over 25 miles of these overhead lines, and he could not remember a single accident attributable to them. The prejudice which existed against them was due to the wretched work done in New York, where they neither suspended the wires nor properly insulated them, but left them to rot, and then people said how dangerous they were. Mr. Mordey had kindly alluded to the arrangement of mains which he was endeavouring to carry out, and which he (Mr. Bailey) did not allude to in the paper because he did not want to advertise himself. There was no particular novelty about it; they were merely acting on mechanical principles, and endeavouring to give people a double supply, one from each end of the cable, so that when a new customer wanted to come on, there was no need to go round to all the subscribers and tell them they must be shut off. With reference to the incandescent lamps, he hoped others would keep a record of the behaviour of all the lamps under their charge, which could easily be done. He had an India-rubber stamp, with a movable date, which was stamped on the cement when the lamp was sent out; when it failed, and was brought in to be replaced, the storekeeper could tabulate the date and the fracture in the filament, and these records would be very valuable. In a few years' time it would be open to anyone to make lamps; and people then would buy from those who produced the cheapest and most durable. Mr. Mordey had referred to the Whitehall Company, and the alteration they had introduced in the other districts as the system developed. That was due to the size of the districts which that company had to light; it was not only a question of providing light, but of doing it quickly, for nowadays, as soon as anyone had his place wired, he wanted the current the next day; and if he did not get it, he worried the life out of the unfortunate engineer to the supply company. He hoped, before long, someone would read a paper showing the benefit to the health of the people conferred by electric lighting, the decrease in headaches and in

doctors' bills. The other day a certain firm took proceedings against an electric light company for not continuing the supply, and stated on oath that whereas with the electric light they could go for six years without decorating their premises, when using gas they had to paint and whitewash every two years, and they claimed damages in consequence. He hoped the vestries would soon see the advisability of lighting the streets by arc lamps.

The CHAIRMAN, in proposing a vote of thanks to Mr. Bailey, said he prophesied two years ago that in ten years time 90 per cent. of all the houses in the West End of London, of £400 a year rental and upwards, would be lit by electricity. He now began to think that he had not been sufficiently sanguine, and that he might have mentioned a rental of £300 instead of £400. So long as gas was supplied at 2s. 9d. or 2s. 6d. per 1,000 feet, the electric light, until improved in some way—and the only improvement that seemed possible was economy in the lamp—must be a light of luxury; but persons who would pay £300 or £400 a year rent, were willing to pay £20, £30, or even £40 more for electric lighting, as compared, not with gas, because many would not use it, but with the other illuminants they employed. After a year's experience of the use of a number of lamps equal to about 114 8-candle lamps, he found the extra cost was between £20 and £25, as compared with the gas, candles, and lamps he used before, and in that he made no allowance for decreased expenditure in cleaning, painting, and matters of that kind, which was undoubtedly considerable. He had also a curious experience, during the summer quarter, of the truth of what Mr. Bailey said about the ease with which the electric light was extinguished and re-lighted. His summer quarter's bill for electric lighting was only a few shillings in excess of the gas bill for the previous year's summer quarter, and he bought no candles or lamp oil, having the electric light all over the house. The reason was simply this, that in a dark London basement, even in the summer time, the gas was kept constantly burning, but the electric light was turned out when not wanted, and though no doubt it was considerably dearer than gas, so much less of it was used, even by the servants, that it only cost a few shillings more.

### ELECTRIC LIGHTING OF THE NEW OLYMPIC THEATRE.

THE new Olympic Theatre, which is situated at the south end of Drury Lane, is now completed, and was opened to the public a fortnight ago. It has been erected, from the designs of Messrs. Crewe and Sprague, by Messrs. Holliday and Greenwood. The theatre is probably one of the safest in the metropolis, there being no less than 18 exits, and ample space everywhere for the comfort of playgoers. It has a lofty auditorium, which, by the aid of a sunlight in the centre, assists in ensuring efficient ventilation. Following the example set by the proprietors of other London theatres, Mr. Chas. Wilmot, who has provided the house for Mr. Wilson Barrett, decided to have it lighted electrically, and Mr. Harry South, of 10 and 12, Garrick Street, W.C., was commissioned to do the work.

The installation is not at present quite completed, but when finished it will comprise about 1,750 incandescent lamps, averaging 16 C.P. The boiler and engine rooms are situated in the basement of the building below the scene dock, and well removed from the auditorium, both being very compactly arranged. In the former are erected two Davey-Paxman locomotive type boilers of 60 H.P. each, working at a pressure of 120 lbs. to the square inch. In the same room the feed pumps and injectors are erected, the latter being worked by exhaust steam, by means of which water is fed to the boilers at a temperature from 190° to 200°.

The engine room contains three compound high speed engines, each of 40 H.P., which were specially constructed for the installation to run at a speed of 390 revolutions per minute. Two of these engines are coupled to corresponding dynamo shafts, which are driven direct; but lack of space prevents the same arrangement being carried out with the third set. In the latter case the dynamo is driven from the engine by ropes, the speed being increased by this means to 550 revolutions per minute. The output of each machine is about 300 ampères, at an E.M.F. of 110 volts.

The main conductors are led to a distributing switch-board, and are divided so that any one, any two, or all three sets can supply any one circuit. The question of

which arrangement should be adopted is determined by the "checks" in the piece, in such a way that any sudden alteration in the load, owing to dark scenes, &c., is immediately distributed over the second or third plant, if the particular one on which it is being run varies beyond a certain limit.

There are in all 45 circuits, each stage section being again divided into three at the "colour board," where the three different colours in which the stage is connected, unite. At the side of this is erected the checking board and resistances, the latter being of an entirely new design, and particulars of which are at present unobtainable.

Continuous practice in theatre lighting has induced Mr. South to seek patented protection for a number of ideas specially applicable to theatre work. These include a novel form of batten, only 6 inches wide and weighing only 2 cwt., a method of separate connection, &c., all of which are brought into use at the New Olympic Theatre.

### NOTES.

**Electric Lighting of Preston.**—During the last six weeks the National Electric Supply Company, Limited, has erected, temporarily, overhead wires, and installed some 300 incandescent lamps' besides arc lamps, in several shops and places. The lights were started for the first time on Thursday last, and created a most favourable impression in the town. The commencement has been a great success, and there is no doubt that the company's present venture here will lead to extensive future business. The whole of the work has been carried out by Mr. F. F. Bennett, late district manager of the National Telephone Company.

**Electric Light in Exeter.**—The City Council had under consideration last week the advisability of applying to the Board of Trade for a provisional order. A letter was read from the secretary of the electric light company, explaining its position with regard to the matter, stating that the company was a local one, and that every effort had been made to meet the wishes of the council. After a long discussion it was decided by a large majority that the council should apply for a provisional order.

**Ship Lighting.**—The Norddeutscher Lloyds' ss. *Gera* left the Clyde on Saturday for Bremerhaven, after going through a series of speed trials in the Forth. The vessel is intended for the emigration trade between the Continent of Europe and South America. An extensive installation of electric lights have been fitted up, and is available in all the passenger departments as well as in other parts of the ship. On the same day the Fairfield Shipbuilding and Engineering Company, Limited, launched the *Oldenburg* for the same company. This vessel will also be lighted throughout by electricity, provided by three engines and dynamos, each furnishing power for 365 incandescent lights. On Saturday afternoon the Palmer Shipbuilding and Iron Company launched at the Howden yard H.M. cruiser the *Pique*, the first of three second-class cruisers placed by the Admiralty with the Palmer Company. The *Pique* will have a complete installation of the electric light.

**Electric Lighting of Inverary Castle.**—Sometime ago the electric light was introduced into several of the rooms in Inverary Castle. We understand the Duke of Argyll now purposes lighting the whole of his castle by electricity.

**Electric Light in Berlin.**—The Berlin Electric Lighting Company now supplies current for 100,000 8-candle-power incandescent lamps, and for 3,000 arc lamps, the total current supplied being 60,000 ampères.

**"The Worst-lighted Town in England."**—At a meeting of the Plymouth Town Council, says a local paper, where public lighting came up for discussion, a councillor expressed the opinion that "they could go into any other town in England and it was better lit than Plymouth." There is an electric lighting company there, but it is beset by financial difficulties.

**Bristol and the Electric Light.**—Last week the members of the Electrical Committee of the Bristol Town Council journeyed to Bath for the purpose of inspecting the installation of the electric light. On arriving at the works they were met by Mr. H. G. Massingham (the proprietor), Mr. Hooker (chief engineer), and Mr. W. H. Preece, and conducted over the works. Subsequently the deputation made a *detour* of the city and acquainted themselves with the public lighting of the streets in addition to the private supply, expressing their unanimous satisfaction with everything they had witnessed. On Saturday the committee held a consultation in Bristol with Mr. Preece. A site for the installation was approved, and Mr. Preece gave it as his opinion that at first the light in Bristol ought to cost very little more than gas, and eventually it would be cheaper, if the corporation managed the supply. Mr. Preece went over the area—from the Victoria Rooms to Temple Meads Station—proposed to be lit, and was instructed to prepare estimates for an installation equal to 60 powerful arc lamps and 10,000 incandescent lights. The scheme, in its present form, is larger than was originally contemplated; but the committee are advised that the period for mere experiment has expired, and they are therefore determined to recommend the council to adopt a system of lighting that shall be permanent, and that shall be so successful as to ensure its very general use throughout the city and suburbs before many years have passed.

**The City and the Electric Light.**—A meeting of the Commissioners of Sewers was held on Tuesday in the Guildhall, when the Streets' Committee brought up a report recommending that the supplying of the western district of the City with the electric light should be entrusted to the Brush Electrical Engineering Company, upon the same terms that they had undertaken to supply the central district. After discussion, Mr. Pannell, who has been one of the principal movers in this matter in the City during the last six years, congratulated the Commission that when this contract was made, two-thirds of the City would have the benefit of the electric light. The report was carried. It was referred to the committee to consider as to the alleged danger of storing electric power.

**Croydon and the Electric Light.**—The County Council has received from Mr. W. H. Preece a detailed report as to the requirements for the probable cost of laying down the electric light in the town. He estimates that a total length of 100 miles of mains will be necessary for the service of the whole district, of which 60 miles can be underground, and 40 miles overhead, the latter being for public lighting only. The underground mains will cost about £700 per mile, the overhead about £230 per mile. To this must be added £2,500 for the feeding mains. The laying of all the mains underground would cost £60,500, or an extra £6,800. In addition to the above-mentioned amounts it will be necessary to provide the installations. Under these circumstances the corporation have decided, in their application to the Board of Trade, to mention £150,000 as the amount of capital which may be employed.

**The Folkestone Electric Light Committee.**—The town clerk states that, instead of the town being put to "the enormous expense of £700" by this committee, as stated at a public meeting, the legal and incidental expenses have not exceeded £120; in addition to which £50 has been paid to Mr. Preece for his opinion on the subject.

**The Barnet Electric Lighting.**—Now that the local authority has determined to end its contract with Mr. Joel, and as his intended application to the Board of Trade for power to supply the light in the district of the East Barnet Valley Local Board has met with no support from that body, we feel interested to learn what the next scene in this little "Comedy of Errors" will divulge. It seems that a return to gas is generally desired.

**London Theatre Lighting.**—The London County Council, debating on the subject of the electric lighting arrangements of the London theatres, has decided to engage Dr. Hopkinson, F.R.S., to report upon the danger, if any, of all the various systems in use. Mr. A. L. Steavenson has written on the subject of the dangers of electric lighting to a Leeds newspaper, recounting his own experience of fires caused by electric light plant in connection with collieries, and he states that a few weeks ago another colliery owner told him that since he had adopted electric lighting there had been two fires, the commencement of the last being actually witnessed by the manager. Yet the *World* states that danger from electric lighting is a sheer delusion. What a world we live in!

**The Electric Lighting Question in Maidstone.**—At a special meeting of the Maidstone Local Board, last week, it was resolved to apply to the Board of Trade for a provisional order. A request, asking the Local Board's assent, authorising the Electric Installation and Maintenance Company to obtain an order for lighting the borough, was refused.

**Serious Accident to Mr. Bernard Drake.**—On Friday last, Mr. Bernard Drake, of Drake and Gorham, met with a serious accident while inspecting the large electric light installation which the firm are just completing for the police authorities at the new Scotland Yard offices. After leaving the Receiver of Police, Mr. Drake passed out of the building by a door leading into the courtyard, which was left ajar, and immediately fell a distance of some 15 feet down an open area, the replacement of the grating of which had been inadvertently omitted. About half an hour elapsed before it was possible to extricate him from the confined space into which he had fallen; but he was eventually conveyed to the Westminster Hospital, where he was found to be suffering from a broken thigh and other injuries. We are informed that he will be confined to his bed for at least two months, and it will naturally be a great disappointment to him to be unable to superintend the completion of the work to which the firm has devoted so much attention during the past six months. We sincerely regret the very serious misfortune which will keep Mr. Drake so long confined, and we trust that his recovery may be complete. With Mr. Gorham we heartily sympathise in being so unfortunately deprived of the valuable services of his active and able partner.

**Commercial Cable Company.**—The *Canadian Gazette* of the 11th inst. says:—Our readers know the high opinion we hold as to these shares, and we are glad to state that at a recent meeting of the directors it was decided to raise the dividend from 6 to 7 per cent. per annum, beginning with the payment to be made the 1st of January next. At the same time the bonds to be drawn in respect of the year now closing will not be £40,000, as heretofore, but £120,000. In addition, there will be a very large surplus to be carried to reserve account.

**Boilers.**—Messrs. Ewen & Co., of Walbrook House, have just issued a revised edition of the section of their illustrated catalogue dealing specially with engines and boilers. With reference to the latter, they draw attention to their loco-type multitubular boilers, which they construct to steam at any pressure according to requirements. In all cases all plate edges are planed, all holes drilled in position, and the riveting and plate bending effected by hydraulic pressure.

**Junior Engineering Society.**—On Saturday the 6th inst., over a hundred members of this society and their friends made an excursion to the Central Institution. According to the printed programme they were received by Professor W. E. Ayrton, vice-president of the society, and were conducted by him over various rooms. In these were displayed a variety of electrical and other apparatus, experiments were performed, and the methods of testing the power and efficiency of arc and incandescent lamps were shown. The busy afternoon was brought to a close in the large lecture theatre. Here the guests seemed much interested in watching the working of a Telpher model. The vote of thanks, which was called for by Mr. Tennant, the energetic chairman of the society, was carried unanimously; and, after it had been suitably acknowledged by Professor Ayrton, the company dispersed.

**Lighting of Steamship Offices.**—The Calcutta offices of Messrs. Mackinnon, Mackenzie & Co., the managing agents in India of the British India Steam Navigation Company, Limited, have been fitted with a complete installation of electric light. The generating plant consists of a "Marshall" 12 N.H.P. compound steam engine erected on a wrought iron frame underneath a locomotive multitubular boiler. The engine drives by belt a "Manchester" compound wound dynamo having an output of 100 volts, 180 ampères, at a speed of 800 revolutions per minute. Throughout the offices, 140 32 candle-power lamps are fixed. The entire work has been carried out by the electrical department of the B.I.S.N. Company's workshops, Calcutta, under the superintendence of Mr. R. J. Browne, the company's electrician.

**Electric Light in Cornwall.**—The electric light has been successfully started at the Kennal Vale Paper Mill, near Ponsanooth (S. J. Polkinhorn). The dynamo was supplied, and the work most efficiently carried out, by Mr. C. J. Veale, of St. Austell. The dynamo is driven by a small 8-inch "Little Giant" horizontal turbine, weighing some 3 cwt., supplied by Mr. S. Howes, which develops six-horse power under a fall of 24 feet, carried by a flume 12 inches diameter, although the power required for driving the dynamo is only some one and a half horse power. This being the first installation in the district, it has excited considerable interest.

Freeman and Son's granite works at Penryn, which have hitherto been lighted by Wells's and other oil lamps, are now lighted electrically.

**Browett, Lindley & Co., Limited.**—The firm of Browett, Lindley & Co., has been converted into a company under the style of Browett, Lindley & Co., Limited, with a view to the immediate extension of plant and manufacturing facilities to meet the increasing demand for their patent "Acme" governors and specialties in high-class steam engines for electric lighting and other purposes. The *personnel* of the firm is in no way altered by the change, as the principals of the late firm are the managing directors of the company.

**Reform Club.**—This club is to be lighted by electricity.

**The Royal Society.**—Last night Messrs. H. L. Callendar and E. H. Griffiths were to read papers on the determination of the boiling point of sulphur and on a method of standardising platinum resistance thermometers by reference to it.

**General Electric Power and Traction Company.**—During the five months ending November, the electric cars of this company operating on the Barking Road section of the North Metropolitan Tramway Company's lines ran 27,597½ out of a possible 27,833 miles. On the 28th of last month, when there was a heavy fall of snow, the cars ran 193 miles out of a possible 213—a better average than was made by the horse cars.

**German Readers Please Note.**—An envelope, much torn, apparently from Berlin, was received, minus contents, by us on the 15th inst. If any one in Germany is awaiting an overdue reply, will he kindly send us a line to that effect.—[EDS. ELEC. REV.]

**International Exhibition, Moscow.**—A scheme is on foot for establishing a permanent general exhibition in the chief commercial city of Russia. Sales will be effected, and orders taken from samples. The agent in this country is M. Emile Cloes, C.E., 122, Cannon Street.

**Lightning and the Electric Light.**—A panic was produced a few days since in the town of Trente (Germany). After a heavy snowstorm, the lightning struck the building which supplied the electric light to the town, and darkness immediately followed. There was, however, more fear than danger, as the light was again available within a few minutes. A performance was taking place at the Teatro Sociale. The audience remained quiet, and the actors, preserving their presence of mind, continued their parts, without interruption, in the darkness.

**Electric Light in Madrid.**—Two companies, one English the other German, have recently obtained concessions for lighting districts in Madrid. The first-mentioned company has received applications for 6,000 lamps; its distribution is by alternating currents. The second employs continuous currents, and has been assured of a minimum service of 11,000 lamps; its station will be fitted with dynamos for the supply of current for 22,000 lamps, and it will be provided with Tudor accumulators, so as to bring the total number of lights up to 40,000.

**Personal.**—The *Elektrotechnische Zeitschrift* states that Lord Rayleigh has been elected honorary member of the Bavarian Academy of Science.

**Electric Organ in Verona.**—An electric organ has been erected in the S. Giorgio Church in Verona by Mr. G. W. Trice, of Genoa.

**Dr. Coffin's Electric Welding Process.**—It is reported that the English promoters of this process are about to establish works in or near London.

**Smoking Concerts in Favour.**—The staff of the General Electric Company held their first smoking concert at the Champion Hotel, Aldersgate Street, on Friday, the 12th inst. The chair was occupied by Mr. H. Hirst, and there was a large attendance, which included a number of well known friends of the firm. An excellent programme was gone through, including an exhibition of the gramophone, which excited considerable interest. It is proposed to hold the next concert on January 23rd, 1891.

**The National Telephone Electrical Society—Midland Branch.**—On Friday, December 5th, in connection with this Society, the President (Mr. Alfred Coleman) in the chair, the Vice-President (Mr. A. E. Cotterell, district manager) gave a very interesting and instructive paper on "A Few Errant Notions on Telephonic Matters." The paper was listened to by a large number of members, and was much appreciated. The Presidential Address was delivered by the President on Friday, November 21st, on "Telephony at the Present Time."

**Quanti est Sapere.**—We are glad to notify that the Council of the Institution of Electrical Engineers has awarded Mr. W. B. Esson the "Institution Premium," for his paper on "Some points in Dynamo and Motor design." This grant, together with his recent accession to the dignity of President of the Old Students' Association, will give Mr. Esson an earnest of the honours which are yet to be showered upon him. May he bear them modestly!

**"L'Electricien."**—From the 1st of January, 1891, *L'Electricien* and the *Revue Internationale de L'Electricite*, which have hitherto been published as separate journals, will appear as one, under the joint titles of the two. M. Hospitalier, we regret to say, owing to the pressure of other work, is unable to continue the editorship.

**O.S.A. Cinderella Dance.**—On Friday evening last a very enjoyable and successful dance was held at the Westminster Town Hall, in connection with the Old Students' Association of the City and Guilds of London Institute. Over 120 were present. In connection with the association, it may be mentioned that an excellent programme has been drawn up for the New Year, including four papers, three concerts, &c.

**An Important Event.**—The General Manager and Secretary of the St. James and Pall Mall Electric Light Company sends us the following note, dated December 17th, but what bearing it has upon the subject of electric lighting is more than we can divine:—"The Right Hon. A. J. Balfour, M.P., and Mr. G. W. Balfour, M.P., this evening visited the central station at Mason's Yard, Duke Street, Piccadilly." We may soon expect to hear that Mr. Parnell has inspected the fire escapes at the headquarters of the London Fire Brigade, or that Sir Charles Russell and Mr. Gill have entered into a partnership with the object of placing before the public a financial newspaper on the commercial morality of which one may absolutely rely.

**Ferranti Mains.**—Touching the remarks we have made on p. 734 on "High Pressure Alternating Mains," it may not be generally known that Mr. Ferranti uses two of his concentric cables side by side with the inner copper tubes connected together in parallel as one lead and the two exterior tubes similarly joined up as the other.

**Gas v. Electricity at Lewes.**—The result of the poll of the ratepayers of Lewes on the question of adopting electric lighting for the public thoroughfares, has been a majority of 25 for gas; the numbers being 177 for this illuminant against 152 for the newer one proposed.

**The City and South London Railway.**—This electric line, the opening of which has been twice prematurely announced, commenced operations yesterday morning. We wish success to everybody concerned.

**The Globe Electrical and Engineering Company.**—We are informed that the business of this company has been transferred to the Electrical Supplies and Fittings Company, Limited, having offices and stores at 2, Carteret Street, Westminster, who are about to issue a catalogue of electrical supplies comprising particulars of their well known manufactures, and of a series of specialities for high and low tension distribution.

**Engines and Boilers.**—A reference to Mr. Bailey's Society of Arts paper will show the rapid development in London of the Babcock and Wilcox boilers and Willans's engines.

**A Correction.**—In our reference last week to the *Oracle*, when mentioning the Electric Construction Corporation, it was intended to refer our readers to our contemporary's pages for Monday, the 8th inst.

**Telegraph Expenditure.**—A report issued on the 18th inst., states that the total expenditure on telegraphs for the year ended March 31st, 1890, was £2,568,799.

**Russian Telegraphs.**—The staff of the Russian telegraph service has under deliberation the construction of a telegraph line along the shore of the White Sea between Kala and the Norwegian frontier. The only present means of communication is a bi-weekly postal service.

**Incandescent Lamp Renovation.**—We understand that Messrs. E. Böhm & Co., of Little Britain, are devoting attention to a process for lengthening the life of incandescent lamps. Discoloured bulbs can be opened and cleaned without interference with filaments or mounting, and it is said that when a lamp is thus treated, and re-exhausted and sealed, it is more durable than a new one.

**The Paris Electric Lighting Companies.**—The four principal electric light companies in Paris, who hold concessions for 18 years from the Town Council, are following the example of the Paris Gas Company, by seeking to obtain an extension of their powers to the year 1930. For this purpose they have submitted to the municipality a memorial offering to reduce the price charged for the electric light, provided their concessions are prolonged to that year. The memorial is under the consideration of the Third Committee of the Council.

**Electrical Industries in the United States.**—The following figures will give an approximate idea of the present development, in the United States, of those industries in which electricity is the chief factor, and which seem to necessitate addition almost every day.

		Force in H.P.
Arc lights ... ..	(number about)	235,000
Incandescence lamps ... ..	"	3,000,000
Electric motors ... ..	"	18,000
" railways ... ..	"	300
" " carriages ... ..	"	2,500
" " length of lines ... ..	"	280 miles
		475,000
		75,000

**Electric Light and Power in a Village of 465 Inhabitants.**—Collais, near Nimes, a village of 465 inhabitants, has just been lighted by electricity. The motive power for the 1,600 light dynamo is derived from a small waterfall. The streets are lighted by 25 lamps of 16 candle-power each. Besides lighting the village, the current is employed during the day in putting in motion the pumps for supplying certain parts of the village with water.

**The Electrical Lighting of the Diamond Mines.**—The installation for the lighting of the underground workings of the Central Diamond Mine, Kimberley, has just been completed, under the superintendence of Mr. R. Oliver G. Drummond. From the second annual report for the year ending 31st March, we find the De Beer's Mine circuit had been running about 15½ months, night and day, with the exception of a short stoppage on Sunday, and during that period there had been no cessation to the light, during working hours, except once, when the engine had to be stopped for 10 minutes to remake a joint. The plant from which the Central Mine is worked is situated within the mining area of the De Beer's Mine, and the company have obtained the right to run their wires through the busiest thoroughfares of the city, from one station to the other, so that they have every facility for lighting the club, public library, post office, court house, and their own private central offices in the diamond market, very cheaply, which they propose to utilise. Many of the large mercantile stores on the route are in treaty with the company, and will probably be supplied from the same source. The Masonic Temple is already lighted from the De Beer's station, and although more than a mile distant, by a system of electrical signals and switches, each ceremony is methodically illuminated, according to ancient custom, without the slightest hitch.

#### NEW COMPANIES REGISTERED.

**J. Tylor & Sons, Limited.**—Capital, £100,000 in £10 shares. Objects: To carry on business as mechanical, consulting, sanitary, hydraulic and electrical engineers and contractors, manufacturers of electrical plant and apparatus, waterworks fittings, &c. Signatories (with one share each): \* W. H. Tylor, \* Joseph John Tylor,

C.E., \* W. B. H. Drayson, \* Philip Bright, J. S. Maples, W. S. Salter, Thos. Allsop, all of 2, Newgate Street. The first four of the signatories are appointed directors. Qualification: 100 shares. Remuneration of ordinary directors, £60 per annum each. Mr. Joseph John Tylor is appointed chairman and consulting engineer, and Messrs. W. B. H. Drayson and P. Bright are appointed managing directors, upon terms to be agreed. Registered 8th inst. by Sydney Morse, 4, Fenchurch Avenue. Registered office, 2, Newgate Street.

**Foreign Electric Date and Time Stamp Company, Limited.**—Capital £100,000 in £1 shares. Objects:—To acquire an invention of an electro-mechanical date and time stamps, patents for which have been obtained in France and Italy. Signatories (with one share each): E. Berlin, 17, All Saints' Road, W.; J. R. Akerman, 139, Minories; J. P. Nurse, 16, Barford Road, Nunhead; G. J. Pocock, 4, Oswyth Road, S.E.; J. L. Stevens, 90 and 91, Queen Street; E. G. Taylor, 46, Brighton Road. The signatories are to appoint the first directors; qualification, £100 in shares; remuneration, £600 per annum, divisible. Registered 8th inst., by F. Fearon, 25, Parliament Street.

### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**J. E. H. Gordon and Company, Limited.**—An agreement of 15th September (filed 1st October), provides for the purchase by the company from J. E. H. Gordon, of 11, Pall Mall, and Wm. John Rivington, of 21, Gledhow Gardens, Kensington, the business of electrical engineer and contractor for the construction and supply of electric light machinery and apparatus, carried on by Mr. J. E. H. Gordon, at 11, Pall Mall. The purchase consideration is £30,000 in fully paid shares. The vendors are appointed joint managing directors for life, each of them to receive a salary of £1,500 per annum.

**Williamson Electrical Engineering Co., Limited.**—The annual return of this company, made up to the 12th inst., was filed on the 13th inst. The nominal capital is £5,000, in £10 shares. 250 shares are taken, and upon these £7 10s. per share has been called and paid, the paid-up capital thus being £1,875. Registered office, 14, St. Ann Square, Manchester.

**Blackpool Electric Tramway Company, Limited.**—The annual return of this company, made up to the 12th inst., was filed on the 13th inst. The nominal capital is £30,000, in £10 shares. The whole of the shares are taken up, 150 being considered fully paid up. Upon 2,850 shares the sum of £6 10s. per share has been called, the calls paid amounting to £18,525.

**Woodhouse and Rawson United, Limited.**—An agreement of 10th inst. (filed 11th inst.), between this company and James Thorne, of 85, Gracechurch Street, cites that by an indenture of 11th February, 1890, it was agreed to issue to the said James Thorne 100 fully paid preference shares, in consideration of the conveyance to the company of a certain invention and letters patent. The said preference shares were duly issued on the 7th February, but 36 of such shares have since been surrendered to the company, and have been cancelled, leaving still issued 64. Although an agreement for the issue of such shares was duly filed, such agreement does not define the distinguishing numbers of such shares, and it has therefore been considered advisable to file an agreement defining such numbers. The said shares are therefore numbered, by the present agreement, from 61,701 to 61,800 inclusive.

**Woodward, Grosvenor, and Company, Limited** (carpet manufacturers, manufacturing chemists, electricians, &c.). The statutory return of this company, made up to the 12th ult., was filed 24th ult. The nominal capital is £90,000, divided into 6,000 ordinary

and 3,000 preference shares of £10 each, 5,000 of the ordinary, and the whole of the preference shares, are taken up, the former being considered fully paid up. Upon the preference shares the full amount has been called, the total of the calls paid being £21,900, and unpaid £8,100.

**Franco-African Lighting Syndicate, Limited.**—At a special meeting of this company, held at 3, Bucklersbury, on the 19th August, it was resolved that the net profits be devoted, firstly, in payment of 10 per cent. per annum cumulative preference dividend, the balance to be distributed amongst the holders of the ordinary shares. If the syndicate be wound up, the surplus assets shall be applied, in the first place, in repaying to the holders of the preference shares the amount paid up thereon, and the residue shall belong to the holders of the ordinary shares. These resolutions were confirmed on the 9th September.

**Earthy Metals Company, Limited** (metallurgists, manufacturing chemists, and electricians).—An agreement of 10th ult. (filed 4th inst.) provides for the purchase by the company from Louis Falero, of 100, Fellows Road, M.F.S.I.E., chemist and electrical engineer, of certain secret processes and inventions for the production, isolation, refinement, and preservation in the metallic state of sodium, potassium, magnesium, and aluminium, and also patent rights in connection therewith. The purchase consideration is 20 fully-paid deferred shares of £50 each. The vendor is appointed managing director for five years. His remuneration is to be an annual amount not exceeding £5,000, as may be equal to one-twentieth part of the consideration to be paid in cash or shares by a new company to be formed, within five years, for acquiring the property and undertakings of the present company.

The statutory return of the company, made up to the 24th ult., was filed on the 5th inst. The nominal capital is £2,000, in £50 shares. 38 shares are taken up, 20 of these being issued as fully paid up. Upon 18 shares the sum of £750 has been paid, leaving £150 unpaid. Registered office, 1, Westbourne Terrace, Willesden Green, N.W.

### CITY NOTES, REPORTS, MEETINGS, &c.

#### The Gülcher (New) Electric Light and Power Company.

At the third ordinary general meeting, held at Winchester House yesterday, Mr. de Castro addressing the meeting, referred to the presence of the reporters. Last year he had a little difficulty with one of the representatives of the press as to whether their meeting was private or public. His view was that it was a meeting of shareholders, and that the public were not interested in the concern, as they were not quoted on the Stock Exchange. It was a question, however, which rested with the shareholders.

A Shareholder considered that it was going back a little to exclude reporters. Other meetings of a like nature were thrown open, and further, as they were nearly in a position to apply for a quotation, it would not be an advantage to exclude the press, he therefore proposed the admission, which was seconded and carried.

The Chairman, in making a few observations, said the period since June had been a very important one for the company. On the date mentioned they had the very small preference capital, comparatively, of £50,000; they had £12,277 subscribed (shown by the report published in the Review last week). They had also a further £6,000 second mortgage debentures, which they were obliged to raise in order to meet the extraordinary difficulty the company was placed in by a contract entered into in New Zealand. He was glad to say that things now were entirely different. They had found that, however prosperous a company might be, or whatever its prospects were, it was hopeless to expect that a company with so small a capital and burdened with such heavy mortgages—£16,000 of them bearing such a very heavy rate of interest—to declare dividends. To pay off the heavy debentures it was necessary to issue the balance of the capital; they accordingly issued the balance of the preference capital, amounting to £37,723. The whole had been subscribed very largely by those who held 10 per cent. debentures, also by new shareholders, who formed an excellent list. The capital, therefore, now stood as the report indicated. They would all admit that they had attained a position which neither the old nor the new companies had ever attained before. The business to which he referred as having plunged the company into difficulties was the undertaking

by mistake of a contract by the late manager, which cost over £13,000, being six times more than was estimated. This accordingly locked up a large sum of money. Looking at the business of the company, he would state at the outset that they were a manufacturing electrical engineering company; they did not supply electricity. The capital required for such a company was much greater. The capital, £136,500, invested in their own concern, left alone, would not pay, it would not produce an income proportionate to the outlay, even if they consented to lock it up; to make it pay, it would be necessary to lay out another £9,000 to produce a substantial interest upon the £25,000 or £26,000. Under these circumstances, it became a matter for the serious consideration of the board as to whether they should employ the uncalled capital. They decided in the early part of the year, if they could possibly do so, to avoid using it to any extent. At the suggestion of the board he had been occupied a greater part of the year in forming a syndicate which would provide, as mentioned in the report, for the lighting of the town of Wellington. It would take over the company's business in New Zealand, together with the benefit which they had in the contract for lighting. The syndicate had at last been formed, and £10,000 would be subscribed, of which the company would only risk £2,000 of their spare capital. He did not think it would be necessary for the company to find one shilling towards it, for he was of opinion that the shares would be applied for by residents in the colony. He hoped, therefore, when he met them again, they would not only be able to report the completion of the contracts, but the completion of the works, which will have been attained by the expenditure of this money, and the receipt of a revenue which would in itself enable them to declare a substantial dividend upon the whole of the capital of the company. There was another phase in the contract formed with the syndicate which was one of considerable advantage. If the company's goods continued to hold the position in New Zealand which they occupied now, the syndicate would become a very valuable customer, and they would gain directly and indirectly by the transaction. Another matter he referred to was the fact of the company contributing to the registration of the South Western District and Thames Valley Electricity Supply Company. In conjunction with powerful people they thought it would be well having regard to the tendency of the electric lighting business to run into central supply rather than into independent installations, to become interested in some district. While London was being portioned out among the great companies, they thought if the way was clear without any material expenditure it would be as well to get a company registered which would tend to secure the monopoly of the district. There was not, he was sorry to say, any net profit, but the gross manufacturing profits were £3,079 2s. 4d. Never since the company had been formed had they made one-third as much, and last year there was a loss of £1,417 6s. 6d., so that this business had improved during the year to the amount of about £4,500. The heavy interest on their mortgage debentures was the real reason they had been unable to declare a dividend; but for that they should have been able to declare a dividend of at least 3 per cent. Mr. Binswanger—one of their late directors—had retired; he had come on the board to represent some large debenture-holders, and since the bulk of the money had been paid off he had left it; while the directors had recently elected Mr. Hilton, a large shareholder, to assist them in the management of the company during the absence of himself, as he was going next week to visit New Zealand to see if he could obtain powers to light not only Wellington, but other towns in the colony. The chairman then went through the various items in the balance sheet *seriatim*. Referring to the paying off of debentures, and the raising of new share capital, he said that when they had applied for £25,000 new capital, the shareholders had come forward with only between £17,000 and £18,000. They had decided, then, not to stop half way, but to get their capital underwritten, paying 7½ per cent. interest. As to profit and loss, for the first time in the company's history this showed sales and receipts exceeding £20,000. They would remember that he had promised them that when their sales exceeded that amount the company would be able to declare a dividend, and he now ventured to say that his figures had been confirmed, for but for the interest on the debentures, they would have been able to declare a dividend of at least 3 per cent., and as the shareholders of the company held most of its debentures, they had received the money as interest, if not as dividend. There had recently been designed for them two very excellent little dynamos, suited to supplying houses requiring 20, 30, 40, or 50 lights, and not within the district of any supply company, as also a little motor, which might be worked from them, and which would do the work of a small gas engine. These had been advertised, and there was evidently going to be a considerable demand for them. Another branch of business that would become more important, in his opinion, than even their business in New Zealand, was that of electric welding. They had made a contract with the only people he knew who had been able hitherto to weld steel and cast iron with any success. They had already had the experiments carried on for nearly two years by customers of theirs, and one of their customers who had taken a plant costing some £1,100 or £1,200, and worked it for a year, had paid himself three times over. This was getting rumoured about, and he anticipated orders shortly from the large firms in the North of England. They had been lighting for the last two years the Spanish and French Exhibitions, and he had at last succeeded in securing the German Exhibition upon similar terms; he had also negotiated for the lighting of a Working Man's Exhibition, or rather of a Labour Exhibition, which was to be held in another part of

London, so that, between lighting the Crystal Palace and these exhibitions, their name would come forward more and more every day.

Major Cotton, in criticising the accounts in a friendly spirit, said the underwriting of the capital was somewhat of a mistake, and he suggested, in case of anything going wrong, the directors would be personally responsible. He regretted that Mr. Binswanger had retired from the board, as he was a most practical man. The directors' fees, as now paid, were very large, considering the work done. They did not go down to the works, and only met once a month, and the fees of £250 each seemed rather excessive. When he was on the board the directors were paid £100. Referring to the New Zealand estimates, it was a dreadfully erroneous affair, and he thought the committee of works ought to have examined carefully the contracts.

After further discussion, a shareholder proposed the election of Major Cotton on the board, but this meeting with the opposition of the chairman, the matter was dropped.

Mr. De Castro and Mr. Hilton were re-elected directors, as also Mr. Russell Day, the auditor.

A vote of thanks to the board concluded the meeting.

### Western Counties Telephone Company.

AN extraordinary general meeting of the Western Counties and South Wales Telephone Company, Limited, was held last Friday at the Grand Hotel, Broad Street, Bristol, Mr. Charles Nash presiding. The Secretary (Mr. Henry F. Lewis) having read the notice convening the meeting,

The Chairman moved the adoption of the following:—

"That the directors be, and they are hereby, authorised by this general meeting to borrow any further sum or sums of money on such security (but not so as to prejudice existing debentures) and terms as to interest or otherwise as they may deem fit, and to secure the same by debentures upon the whole or any part of the property, funds, assets, or effects of the company, and so that any sum not exceeding £80,000, including the £50,000 previously authorised and issued, may be owing at one time, but so that the money to be borrowed under the authority of this resolution or consent shall not bear a higher rate than 6 per cent. per annum, nor (without the consent of the National Telephone Company, Limited), a higher rate than 5 per cent. per annum." He would say a very few words upon the progress of the company's business during the present year. The number of subscribers to the exchange and to the trunk lines in 1885 was 779, in 1887 it had increased to 2,034, and in November, 1890, it had increased to 3,540. As to receipts, after the payment of royalties, they had increased from £8,064 in 1886 to £21,286 in 1889, and judging from the progress made during the present year he had no doubt that the amount for 1890 would exceed £26,000. It was also satisfactory to find that the increase was going on at a more rapid ratio than it was last year. In 1889 the increase in the business was at the rate of £325 per month; during the present year the increase had been at the rate of £411 per month—so that the increase on that of last year had been at the rate of about £1,000 per annum. All that had required capital to be expended, and that was the reason of the proposal now to issue £30,000 on 5 per cent. debentures. He need not say much about that. They believed the security was an excellent one. The surplus remaining last year, after paying interest on existing debentures, was £6,848. The surplus this year would certainly be very much larger, and the interest upon the debentures now proposed to be issued would be only £1,500, so that it appeared to the directors that the security offered was a very excellent one.

Mr. Read seconded the motion. He remarked that the progress of the company's business was satisfactory to the shareholders in every sense.

In reply to a question as to the expiration of certain patent rights at a future period, it was stated that the company were covering their district so well that there would be little or no room for any competing company.

The motion was unanimously adopted.

**Greenwood and Batley, Limited.**—The directors have declared an interim dividend at the rate of 7 per cent. per annum on the preference shares; but have decided to postpone the consideration of a dividend on the ordinary shares until the end of the financial year.

**The West Coast of America Telegraph Company.**—The coupons due December 31st on the debentures of this company, will be paid by Messrs. Barclay and Co., Lombard Street. Coupons should be left three clear days for examination.

**The West African Telegraph Company.**—This company announces an interim dividend for the six months ended June 30th, of 4s. per share.

### TRAFFIC RECEIPTS.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending December 12th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Ltd.

## SHARE LIST OF ELECTRICAL COMPANIES.

Present Amount Issued.	Name.	Stock or Share.	Closing Quotation. (December 11).	Closing Quotation. (December 18).	Business done during week ending December 18, 1890.

CONTINUATION of discussion on "The Working Efficiency of Secondary Cells" and "Notes on the Chemistry of Secondary Cells," by Prof. W. E. AYRTON, C. G. LAMB, B.Sc., E. W. SMITH, and M. W. WOODS.

(Authorised Abstract.)

Mr. S. JOYCE, jun., said he had gained some experience with pasted cells when discharged at high rates, and therefore requiring frequent repairs. After several repastings he found it very difficult to make the red lead paste stick in the positive plates, and then tried litharge paste similar to that used for negatives. Cells so made had proved very satisfactory.

Mr. D. G. FITZGERALD enquired by what authority, and for what reasons, the authors called the peroxidised plate the positive, and the spongy lead plate the negative? He, himself, had good reason for reversing the designations, and in this he was following the example of Volta and Berzelius. Speaking of the chemical constitution of the negative (peroxide) plate, he said it was generally believed that  $PbO_2$  enters largely into its composition; there is, however, reason to doubt whether any of this compound is present, for the behaviour of the active substance on the plates is quite different from that of the pure peroxide of commerce. If a plate be made up of 80 per cent. of pure peroxide and 20 per cent. of the so-called peroxide produced by electrolysis, the E.M.F. falls when the electrolytic product is spent, and the subsequent action of the cell is unsatisfactory. In his analyses of the electrolytic peroxide he had always found some percentage of moisture present, even after it had been dried at a temperature above  $212^\circ F$ . He believes the chemical changes produced by electrolysis is represented by the equation  $(PbO_2)_{10}, (H_2O)_5, PbSO_4 = (H_2PbO_5)_5, PbSO_4$ , and that electrolytic peroxide is  $H_2PbO_5$ . As regards the best kind of support or grid for the spongy lead, he said it was a mistake to use lead, for copper is in many cases much better. If the copper be left exposed local action takes place, but this is retarded by the addition of any alkaline sulphate. The beneficial effect of soda in secondary cells he attributed to the formation of a double salt which is easily reduced. Sulphate of magnesium has an extraordinary influence on lead plates, and by using a solution of it as electrolyte, he had got discharges 30 or 40 times greater than those obtainable from sulphuric acid. The strength of acid required attention when dealing with heavy discharges. Recently he had used acid having a maximum density 1.252, so that its specific resistance diminished as the cell discharged; in this way, and by the aid of copper supports for the spongy lead, he obtained a comparatively steady discharge of 2 amperes per pound gross weight of cell for 2 hours. With ordinary lead grids this would have been impossible.

Prof. PEREY asked the distinguished chemists present if the double sulphate really exists, and Prof. Ayrton inquired whether there were any simple tests, by which such sulphates, if formed, could be detected.

Dr. GLADSTONE said Mr. Hibbert and himself had concluded that there was no evidence of double sulphates being formed in the action of secondary cells. He believed the general idea as to the influence of sodium sulphate was that lead sulphate was more soluble in the mixture than in simple acid; this, however, was not confirmed by experiment.

Mr. CROOKES, the new president, said sulphuric acid had a great tendency to form double salts, and thought it very probable that such salts would be formed in the case under discussion. Some results published by Dr. Gore in the *Phil. Magazine*, also point to the same conclusion.

Prof. S. P. THOMPSON was interested to learn that, like any other battery, the greatest action occurs at the upper parts of the plates. This might perhaps have been expected, because of its being the path of least resistance, but as the variation of the resistance of sulphuric acid with density is peculiar, and as the denser acid falls to the bottom, the action might have been modified thereby. The details relating to the formation of plates, given in the second paper, were, he thought, not new, and were practically what any one having a knowledge of the properties of the substances used and of the reactions which it was desired to bring about, would have arrived at theoretically. For example, to oxidise the positives one would aim at producing the most powerful oxidiser in the shape of ozone, the formation of which is facilitated by strong acid, large current density, and low temperature. On the other hand to reduce the litharge on the negatives it was known that a large current density mainly produces gas, and that reduction is best effected by small current density, at a fairly high temperature. Bearing in mind these opposite conditions one readily realises that the plates should be formed separately and that the negatives will require a much longer time. Several years ago he tried cells with electrolytes other than sulphuric acid and found that phosphoric acid was the only one which gave fairly good results. Speaking of pasted cells, Dr. THOMPSON inquired whether the authors had noticed that the oxidation of the positive paste begins near the grid, and gradually spreads through the mass of the plugs, and whether a useless nucleus remained unacted on in the centre of each.

Replying to Prof. Thompson, Mr. E. A. HALL said he had made experiments on the capacity of cells with plates of different thickness, and found it independent of the thickness. This, he thought,

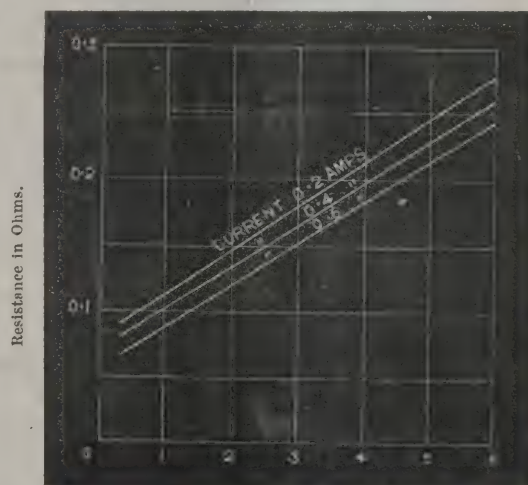

tended to confirm Prof. Thompson's view as regards a useless nucleus. On the question of acid density he found that the capacity of a cell was increased 15 per cent. by using acid of specific gravity 1.15 instead of 1.20.

Mr. PREECE rose to correct an error made by Mr. Drake at the last meeting in stating that the density of acid in the P. and O. battery had been 1.40. Mr. Hall informed him (the speaker) that it had never exceeded 1.22.

Mr. T. FRAZER took exception to the remarks made by Mr. E. W. Smith, in his reply to the discussion at Edinburgh, with reference to the formulae he (Mr. Frazer) had given for the resistance of cells for different currents, and for the fall of E.M.F. when the charging circuit is interrupted. In spite of what Mr. Smith said he maintained that his own statements were correct.

Prof. AYRTON, in replying, said the authors greatly appreciated the cordial reception given to the papers by practical engineers, for one of the aims of the Central Institution was to train students to do work and carry out investigations, the results of which would be of commercial value. Referring to Dr. Gladstone's criticism about the ammonium acetate method, he said that Mr. Robertson had used this method, but somehow or other the paragraph describing it had not been printed in the first proof. Speaking of measuring the resistances of cells, he pointed out that unless the curve connecting time and E.M.F. was discontinuous at the instant of breaking circuit, the method used should give correct results. So far as he knew there was no evidence of any such discontinuity. Mr. Crompton had said the resistance was practically independent of the distance of the plates apart, and that the sulphating of the negatives during rest depended greatly on light. Taking the case of resistance first, they had made experiments on a small two plate cell, and found that when the ordinary method of testing was employed Mr. Crompton's statement seemed nearly correct, but on using the more sensitive method illustrated in figs. 10 and 11 of the Edinburgh paper, this was not the case. Diagram A

DIAGRAM A.

Distances of plates apart in inches.  
Resistances of small secondary cell. Plates  $\frac{1}{4}$  inches  $\times$   $\frac{1}{2}$  inches.

represents the results of these experiments. To investigate the effects of light, darkness, and sulphate of soda on the liberation of gas from idle negatives, they had experimented on three similar E.P.S. cells. The fully charged negatives, designated by A, B, and C, respectively, were put in three different vessels of acid, one of which contained 0.8 per cent. of sodium sulphate, and the gases collected. A powerful arc light illuminated one set of plates whilst the other were kept dark. Plate A, when illuminated, gave off gas very rapidly, whilst B and C in the dark produced very small quantities, which were about equal. On interchanging the plates, however, it was found that neither light or sodium sulphate had any marked effect on the rate at which gas was given off, for whether A was illuminated or kept dark, or put in ordinary acid, or in the sodium sulphate solution, gas was liberated rapidly at about the same rate, whilst B and C were equally inactive under all the conditions. They therefore conclude that the rate at which gas is liberated depends on some peculiarity of the plates themselves. Some speakers, he said, had remarked that many of the facts brought forward in the papers were previously known. To this he replied that none of the facts given as new were known to the authors before they discovered them experimentally. Manufacturers might have been aware of them, but if so, they had kept them secret and never published them. For example, Dr. Gladstone, one of the highest authorities on secondary cells, was not aware of the differences in the hardness of the plugs at different parts of the plates until the appearance of their paper. Another case in point was the fact that Dr. Thompson said there was nothing new in the methods of forming the plates, whereas Mr. King apparently did not know of them. Mr. Swinburne had also called their attention to a prediction of the cooling of cells during discharge made in 1887, but at that time he admitted that he had not observed it. Speaking of the efficiency of cells, he said some people think the very perfect testing apparatus gave the cells their high efficiency; this, of course, was not true, for their figures merely express the results obtained when cells are used in a proper manner. Referring to a criticism on the Edinburgh paper, which appeared in one of the leading technical papers of July 25th, he said the writer had

only partly understood the early part of the paper, for they (the authors) had there explained that one of the objects of the investigation was to see what error could be made by neglecting the previous history and the resuscitating power of cells. The same writer had also stated that the results of laboratory tests were not applicable to ordinary working conditions. Here, again, he had fallen into error, for a secondary cell is a thing complete in itself, and if two or three selected at random give good results under proper treatment, so any number if similarly treated will show equal efficiency.

Correction in previous abstract.—The third word from the end of last sentence but one of Mr. King's remarks should be "circuit" instead of "surface."

### Physical Society.—November 28th, 1890.

Prof. W. E. AYRTON, F.R.S., President, in the Chair.

The following communications were made:—

"Additional Notes on Secondary Batteries." By D. J. H. GLADSTONE, F.R.S., and Mr. W. HIBBERT, F.I.C. After referring to the debateable points as to what compounds are formed and decomposed in the working of such batteries, the authors give the results of their examination of the red substance formed by the action of dilute sulphuric acid on minium, and which, Dr. Frankland believes to be a compound having the formula  $Pb_3S_2O_{10}$ . The ultimate analysis showed 72 per cent. of lead. A portion of the substance was treated with a 3 per cent. solution of ammonium acetate to dissolve out any normal sulphate that might be present; this left a residue much darker in colour than the original substance and containing 82 per cent. of lead.  $PbO_2$  contains 86.6 per cent. of lead. The colourless solution yielded a ratio of Pb to  $SO_4$  varying from 2.0 to 2.15; pure  $PbSO_4$  requires a ratio of 2.16 and Dr. Frankland's compound 3.23. From these results the authors conclude that the portion dissolved was not a basic sulphate, and that the evidence tells against the original substance being a chemical compound. The authors have also continued their comparative experiments in the action of spongy lead on dilute sulphuric acid, either pure or containing a small quantity of sulphate of soda. After the experiments had gone on for five months, the residues were analysed; that from the pure acid showed 82 per cent. of lead sulphate and 18 per cent. of metallic lead, whilst that mixed with sodium sulphate gave 89 per cent. of lead sulphate and 11 per cent. of lead. They therefore conclude that although the action of acid on lead is initially diminished by the presence of sodium sulphate, the final result is rather the other way.

Mr. G. H. ROBERTSON, who had used ammonium acetate to analyse plugs from storage cells, said he had arrived at results much the same as those stated by the authors.

Mr. SWINBURNE said Dr. Frankland was absent, but without agreeing with him, he would suggest that Dr. Frankland might say that ammonium acetate decomposed the subsalt  $Pb_3S_2O_{10}$ , and then dissolved the sulphate  $PbSO_4$ . The question might be attacked by acting on equal quantities of the substance, and the mixture  $PbO_2$ ,  $PbSO_4$ , in a calorimeter with ammonium acetate, to see if the same heat is produced; this would show whether the substance is a mixture or a compound.

Dr. S. P. THOMPSON was glad that the authors allowed a possibility of basic sulphate being formed, for it is well known that an almost irreducible sulphate resulted from leaving a cell nearly discharged; this he thought would point to a possible formation of a basic sulphate from  $PbO$  and  $PbSO_4$ .

Mr. SWINBURNE did not see where the  $PbO$  came from, except in newly pasted negatives, and he knew of no evidence of an intermediate stage of oxide on the plates. They appear to change directly to sulphate.

Dr. THOMPSON said that a rapid discharge was known to produce basic salts.

This, Mr. SWINBURNE thought due to deficiency of acid near the plates. Peroxide, he said, could not be formed on the negative without the acid was heterogeneous and gave rise to local currents.

Mr. W. HIBBERT, referring to Mr. Swinburne's statement, said he had put one plate of spongy lead into strong acid and another into weak, and from this arrangement obtained a fairly large current. As regards the basic sulphate spoken of by Dr. Thompson, he did not think there was much probability of its being formed. Time, he said, had an important influence on a partially discharged cell, and he would not expect to easily reduce the  $PbSO_4$  formed by the long continued action of lead on sulphuric acid.

The PRESIDENT enquired whether Mr. Hibbert's argument would apply to a fully charged cell.

Mr. HIBBERT, in reply, said that in this case the time required to produce sufficient sulphate to be irreducible would be very much longer, for in a partially discharged cell much sulphate was already formed.

Dr. GLADSTONE said he had anticipated that Dr. Frankland would raise the objection referred to by Mr. Swinburne. As far as he was aware there was no direct evidence either way, but he thought the suggested decomposition was improbable. If he acted on a mixture of  $PbO_2$  and  $PbSO_4$  he would expect to get the results actually obtained. Mixtures, however, were difficult to deal with, and the results not conclusive, for the physical condition of the mixture was not the same as that of the actual pro-

ducts. Referring to Dr. Thompson's remarks, he understood that it was the basic sulphate which he (Dr. Thompson) considered irreducible. Dr. Frankland, however, believed this sulphate more easily reduced than  $PbSO_4$ .

The PRESIDENT remarked that he thought Dr. Frankland had two reasons for his belief in the existence of the basic sulphates. One of these was the difficulty in reducing normal sulphate, whilst the other was based on the rapid fall of E.M.F. at a certain part of the discharge. It was at this point that Dr. Frankland thought the new sulphate formed, and to meet this argument it was necessary to find some other explanation of the rapid fall. In this connection he (the President) enquired whether there was sufficient peroxide formed on the negative plate to account for the drop.

On this point Dr. GLADSTONE could not speak decisively.

"An Illustration of Ewing's Theory of Magnetism," by Prof. S. P. THOMPSON, D.Sc. A number of small "charm" compasses were placed together on a glass plate of an ordinary vertical attachment to a lantern. A large magnet at a distance served to neutralise the earth's field, and a coil enabled a magnetising force to be applied in the plane of the needles. By this apparatus all the various phenomena exhibited by Ewing's model were beautifully shown on a screen. In the course of his experiments Dr. Thompson had found that when small magnets placed at moderate distances apart were used, it was much more necessary to neutralise the earth's field, in order that they might set themselves according to their mutual attractions, than when larger magnets were employed. A weak field directed the small openly spaced magnets, whereas with larger ones their mutual actions were much more powerful. This fact may, he thought, throw some light on the molecular groupings in magnetite (loadstone). This substance exists in two forms, viz., one crystalline, and the other of a heterogeneous structure. The former variety exhibits no magnetic retentiveness, whilst the latter is decidedly magnetic. As far as he was aware no sufficient explanation had been given of the non-retentiveness of the crystalline variety. A difference in the molecular distances, or groupings, might account for the peculiarity.

Mr. BOYS said it was rather curious that Prof. Rücker had just devised a somewhat similar illustration of Ewing's theory, and he exhibited it at the meeting. It consists of little magnets made of long V-shaped pieces of watch spring pivotted by glass caps on needle points; the needle points are fixed in little discs of lead stuck on a sheet of glass which forms the base of a glass box. An open helix surrounding the box serves to apply magnetic force.

Mr. SWINBURNE called attention to two theoretical points. First as regards susceptibility (which he regarded as a mere ratio and not a property), he said that if particles of iron at a high temperature rotate, as has been supposed, the susceptibility should be negative, and Prof. Ewing had some reason to think that this was the case. The next point concerned the loss of energy when an armature rotates in a strong magnetic field; this, he said, was known to be considerable, whereas if Ewing's theory is correct, he would expect little or no loss, for all the little magnets would always put themselves in the direction of the field and would never pass through positions of unstable equilibrium.

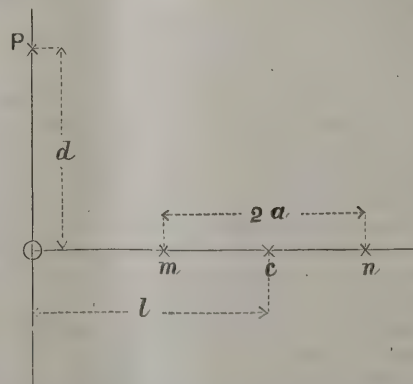

The PRESIDENT said he had discussed the question of negative susceptibility some years ago with Dr. Lodge with reference to the drop in the characteristics of dynamos, but he was not aware that any direct evidence had been obtained.

Prof. PERRY thought negative susceptibility might be possible in strong fields but not in weak ones.

Mr. SWINBURNE, on the contrary, considered its existence would be more marked in weak fields.

Mr. H. TOMLINSON said he had tried experimentally whether the susceptibility of nickel, when heated above its critical temperature, was negative, but he had not been able to detect it, although his apparatus was very sensitive.

"The Solution of a Geometrical Problem in Magnetism," by THOMAS H. BLAKESLEY, M.A. The problem referred to was the following:—Given the two poles of a magnet and a straight line intersecting at right angles, its axis produced, to determine at what point this line is parallel to the field. The question is of

scientific interest, because if the point be found experimentally, the distance between the virtual poles of the magnet can be determined, whilst it is important practically, from its bearing on the deviation of ships' compasses in certain cases. The instances in which it would apply are pointed out in the paper.

Assuming the points  $m$  and  $n$  (see fig.) to be the portions of the virtual poles and  $r$  the required point, it is shown that—

$$\frac{m}{(d^2 + m^2)^{\frac{3}{2}}} = \frac{n}{(d^2 + n^2)^{\frac{3}{2}}}$$

where  $o m = m$ ,  $o n = n$ , and  $o r = d$ .

From this expression  $\left(\frac{d^2}{2 m n}\right)^3 - \frac{3}{2} \frac{d^2}{m n} - \frac{1}{2} \frac{m^2 + n^2}{m n} = 0$

is deduced.

Now in hyperbolic trigonometry we have a formula—

$$\cosh^3 \theta - \frac{3}{2} \cosh \theta - \frac{1}{2} \cosh 3 \theta = 0.$$

Hence, making  $\frac{m^2 + n^2}{2 m n} = \cosh 3 \theta$  we have also  $\frac{d^2}{2 m n} = \cosh \theta$ .

The value of  $\theta$  can be then found by aid of the tables of hyperbolic sines and cosines compiled by the author and published recently by the Society. The distance,  $d$ , can thus be determined in terms of  $m$  and  $n$ .

A method of finding the point experimentally is then described, and the distance between the poles ( $2a$ ) shown to be given by the expression  $\frac{a}{l} = \tanh \frac{3 \theta}{2}$  where  $\frac{l}{d} = \sqrt{\frac{\cosh 3 \theta + 1}{4 \cosh \theta}}$ ,  $l$  being the

distance  $o c$ . The latter function can be deduced from the tables already referred to.

Experiment shows that the distance between the virtual poles soon approaches the length of the magnet, as  $d$  increases.

The strength of the field at  $r$  is given by the expression  $\frac{4 M}{d^3} \frac{\cosh^2 \theta}{4 \cosh^2 \theta - 1}$  where  $M$  is the moment of the magnet. This

can be simplified by arranging  $d$  and  $l$  so that  $\cosh^2 \theta = \frac{5}{4}$  and

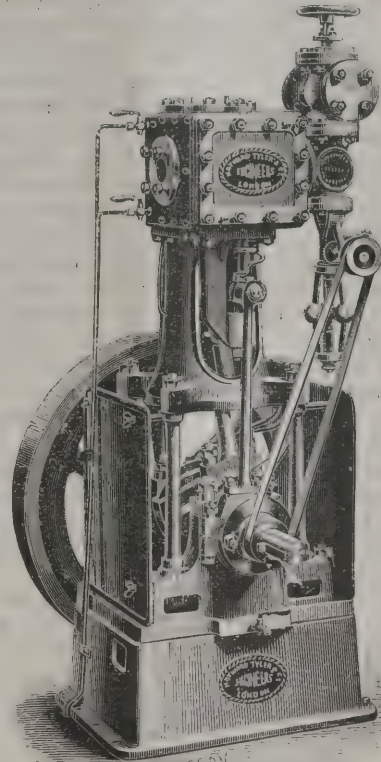

then becomes  $\frac{5 M}{8 d^3}$ .

Under these conditions  $\frac{l}{d} = .85065$  and therefore the angle  $o c r = 40^\circ - 23' - 10''$ .

## VERTICAL HIGH-SPEED ENGINE FOR ELECTRIC LIGHTING.

WE give an illustration of a new vertical high-speed engine constructed by Messrs. Hayward Tyler & Co., of Whitecross Street. It is of the single-cylinder double-acting high-pressure non-condensing type. The general design is new, consisting of a strong cast iron bed-plate having four mild steel vertical columns secured into suitable bosses. These columns carry a cast iron superstructure forming the guide bars, and a connection for the lower end of the steam cylinder. The bed-plate has the main bearings cast in one piece with it, and is provided at its lower edges with a capacious channel for catching waste oil. The cylinder is  $7\frac{1}{2}$  inches in diameter, and the piston has a stroke of 7 inches. The piston is of cast iron very deep, and fitted with Ramsbottom rings. The slides are of cast iron with ample surface. The valve is of a special double-ported type with short travel, and is connected to the valve rod by a circular gun-metal nut with a lock-nut and pin. The crosshead is fitted with square-bottomed gun-metal bearings, and a cap of steel forged solid with the guide slippers which are accurately turned and scraped to fit the guide bars. The connecting rod is of mild steel. The crosshead end is provided with a fork in which the steel crosshead pin is firmly shrunk. The lower end is of marine pattern with gun-metal bearings with flat backs, and having very ample surface. The crank shaft is of steel of double web type with large balance weights in one piece with the webs. The valve spindle is of steel of large diameter, forged solid with the guide, which latter is of extra size. The eccentric rod is of mild steel, with a bushed eye at the upper end, and a palm at the lower end for attachment to the eccentric strap. The eccentric is of cast iron, very wide, provided with a reversing plate, so that by simply changing a bolt the engine may be run either way. The eccentric strap is of best gun-metal of the stiffest shape and section, provided with steel bolts and extra deep nuts. The main bearings are of best gun-metal fitted into bored seats in the

bed-plate, secured by driven gun-metal stop pins. The governor is of the high speed type acting directly on a double-beat perfect equilibrium throttle valve, and is so constructed as to have no joints. It is adjustable whilst running. A heavy turned and polished fly-wheel is securely keyed to the outer end of the crank shaft close to the main bearing. The diameter is 3 feet, width 5 inches. A strong cast iron base-plate carries

the fly-wheel well clear of the floor line, faced on the upper surface, and provided with hand holes for bolts and a strong flange for securing to the foundation. Two lubricating boxes are fitted in suitable positions, so that by means of copper pipes the oil is carried to every bearing. Special means of carrying the oil from the lower ends of the pipes to the bearings are adopted, so that the whole can be oiled while in motion, and thus obtain constant running if necessary. Every part has been made strong enough for a steam pressure of 180 lbs. per square inch. The bearing surfaces throughout have been most carefully considered so as to secure perfect running. A speed of 350 revolutions per minute is about the best, but the engine will run without trouble at 450 if desired.

## COMMUNICATIONS FROM ITALY.

[FROM A CORRESPONDENT.]

THE alternating current central station erected at Venice by the Edison Company of Milan has, in consequence of the still growing demand for the electric light, been again enlarged by the addition of a fourth alternating current machine for 80,000 watts and the accompanying transformers. The electrical works at Venice are thus raised to the total capacity of 320,000 watts.

The same company is at present erecting at Intra an extensive electrical works on behalf of a local manufacturer named Sutermeister.

A large water-power is to be utilised by the transformation of its energy into electricity in order to supply electric light and motive power to the establishments in the valley. This installation presents an especial interest, since alternating currents are to be used both for lighting and for the transfer and distribution of

power. Consequently the electric installation of Sutermeister at Intra will be the first in which the alternating current will be used on an extensive scale for the transfer and distribution of power. The electric works are in the first place to comprise four turbines, of 150 H.P. each, and as many alternating current machines with the accessory exciters and accompanying apparatus, and they are now being begun with the erection of two turbines and dynamos.

The Italian villages Nicastro and Villaggio Bella have resolved on the introduction of the electric light to be supplied from a single central station to be erected at Nicastro. For public lighting in Nicastro, there are proposed 150 glow lamps of each 16 candle-power, 40 of 25 each, and 10 of 100 each, and, further, three arc lamps. For the streets of the village Bella, altogether 20 glow lamps of 16 normal candle-power each. The distance between the central station at Nicastro and the village Bella is about 1,300 metres. The installation, with regard to this distance, will work on the three-lead system, with an initial tension of 400 volts, and a tension of 200 volts at the lamps. To this end there are to be set up two "Oerlikon" continuous current dynamos, each for 65 ampères and 200 volts, which supply the three leads not in series with a current of 400 volts at the furthest conductors, whilst the lighting will be effected with glow lamps at 200 volts.

An official decree has been taken as the basis for lighting Monteleone di Calabria, where the electric works will be erected about 1,200 metres from the town. Here one place only has to be lighted, and that with a smaller number of lamps.

At Tivoli, the works for the extensive electrical installation of the Roman Gas Company are progressing, the workmen being already busy with the erection of the turbines and the dynamos in the central station. The formal opening is fixed for May, 1891.

### LIGHTING OF A POWDER MILL.

A RECENT issue of the *Bulletin International de l'Electricité* contains a description of the electric lighting of the National Powder Mill of St. Médard-en-Jalle. The directors had erected a small experimental plant at first, in order to test the applicability of the electric light throughout the works. The lighting being found satisfactory, MM. Sautter, Harlé & Cie., were instructed to put up a complete installation, which is now in full operation. There are installed nine arc lamps of 1,500 C.P., and a number of incandescent lamps, which are protected against breakage by glass globes and wire guards. Owing to the various buildings being some distance from each other, it was not easy to carry out the lighting arrangements. It was necessary to instal glow-lamps in buildings 975 yards from the generating station, and to maintain a constant potential of 110 volts at the end of a conductor of 45 mm. square section, whilst the consumption of current might vary from zero to 120 ampères. These objects have been attained by the employment of an extra compound-wound dynamo having two windings. One of these is in series and the other in shunt, and separately excited at a constant potential by an independent dynamo. The working of this machine has answered the anticipations put forward. When fully loaded, the loss in voltage at the distributing centre does not exceed 6 volts, and the independence of the arcs has been obtained. Two relays, one having a green and the other a red lamp, are placed in the engine room, so that any variations in the E.M.F. due to any change in the speed of the exciter may be ascertained. The dynamo, which runs at 800 revolutions, works 18 hours out of the 24 with a variable load.

## CORRESPONDENCE.

### Underground Cables.

Your issue of the 5th inst. contained a letter from Mr. C. H. Yeaman, to which was appended a communication from the Liverpool agent of the India-rubber, Gutta-Percha and Telegraph Works Company, of Silvertown, written under the direction of the London house, and containing two statements which are inaccurate and misleading, and which are liable, if uncontradicted, to injure our business. The statements are as follows:—

(1) "At West Brompton the Fowler-Waring cables on trial there have been abandoned, and our vulcanised rubber cables are exclusively used."

(2) "We believe the Fowler-Waring cables have been condemned; the reason Mr. Ferranti did not order the 10,000 volt cable from us is that he did not consider that they were within the bounds of possibility, commercially."

In reply to the first of these statements, the cables supplied to our company to the House-to-House Company at West Brompton have not been abandoned, but their use has been postponed owing to the difficulty of making two T joints on heavy lead-covered cables in a joint box  $3\frac{1}{8}$  inches  $\times$   $3\frac{1}{8}$  inches  $\times$  10 inches.

This difficulty is a serious one, but, I believe, we shall completely overcome it. Mr. Hall, the manager of the West Brompton Company, authorises me to add that the cables supplied by us, when tested in water, gave a higher insulation resistance than any of the cables supplied by the Silvertown Company; he assures me that only the difficulty I have referred to has prevented the extensive adoption of our cables.

In answer to the second statement, it is untrue that the cables we have supplied to Mr. Ferranti have been condemned; but as I understand Mr. Ferranti himself will deal with some of the other statements in this misdirected canvasser's epistle, I am content to leave any further remarks on this subject to him.

It is only due to the Silvertown Company to observe that they leave to agents the ungracious task of propagating inaccuracies and misrepresentations intended to injure their rivals.

Alfred E. Mavor, General Manager.

For the FOWLER-WARING CABLE COMPANY, LIMITED.

9th December, 1890.

In your issue of November 21st you publish a most interesting paper by Mr. C. H. Yeaman, "On Lighting from Central Stations. You also publish in your issue of December 5th a letter written to Mr. Yeaman by the Silvertown Company. In both of these publications my name is mentioned, and facts are not stated as correctly as I should have liked to have seen them.

To begin with, I may say that the amount of "wild talk" about 10,000 volts is quite unwarranted, especially as the people who speak about it have, practically, no knowledge on the subject. 10,000 volts, although it can be worked, and machinery and cables made to stand it, is not a thing which at the present moment is as easily dealt with as some people may imagine. Moreover, I may say that a cable which has to be used for a daily supply of 10,000 volts must be able to stand a very prolonged test of 25,000 volts at least with a considerable horse-power at the back of it.

Now, as regards the statement as to the abandonment of the Fowler-Waring cable by the London Electric Supply Corporation, Limited, I may say that this is quite incorrect. The only trouble that there has been with the Fowler-Waring cables has been in what they have been called, not in the cables themselves. They were, and are first class cables for the purpose for which we are using them, viz., the supply of current at 2,500 volts. If the cables were required for a higher

pressure they would have to be more heavily insulated, and this no doubt can easily be understood.

I may also add that our permanent distributing work is being done with insulators other than India-rubber, and that I do not propose to use India-rubber where I wish to have a lasting permanency.

S. Z. de Ferranti.

December 11th, 1890.

#### Improvements in Telephone Switchboards.

I should be glad if you could find room for a further letter on this interesting subject in reply to that of Mr. H. F. Jackson in last week's REVIEW.

In criticising my criticisms your correspondents have introduced arguments tending to show how the "improved" board would work if it had some other attachments than it has, or were in fact some other kind of board than it is; and Mr. H. F. Jackson refers to the single-cord system. The single-cord system is, telephonically, of remote antiquity, and it has been developed to a point of speed and easy manipulation which your correspondents do not apparently appreciate. But, so far as my information goes, those who have developed it and are fully cognisant of all its advantages, do not recommend its adoption for small exchanges. I have taken great care to prevent the assumption that the single-cord system was at all involved in the discussion, and the words "single-cord board" in this letter will be understood to refer only to the one of which a description was published in your columns on October 24th. I can now go back to the original questions raised by that description, viz., whether the single-cord board is superior in operating to a double-cord board with speaking keys, and which of the two is the more suitable for adoption in small exchanges.

In my article I referred to advocates whose opinions were entitled to respect. Mr. Jackson is clearly one of those. It is satisfactory that his opinions, and the grounds for them, have found expression.

I agree fully with Mr. Jackson in the two points to be aimed at. The first point is met exactly by the double-cord board; much depends upon the way in which the second is interpreted; and I would add a third to cover facilities for extension.

In regard to 1 (a): The insertion and removal of a plug count two for both boards. Any other value may be given them, but it must be on both sides of the account. That it may be seen my comparison was not unfair, I will examine Mr. Jackson's reasons for a reduction: It is because the first three movements are made with the same plug. There is a conversation between one and two. Frequently there will be ringing as well. Movements two and three are more nearly related, but are no quicker than plug movements, counting two on the double-cord board. There is no advantage by reason of the movements being made with one plug. There is a disadvantage which I will show later.

I have no difficulty in giving my reasons for asserting that the double-cord movements are done more quickly, and I think it will be seen that in practice it must be so. The time occupied in any operation depends on the mechanical work to be done, and the mental effort required to do it. There are seven plug movements, against five plug and two speaking key movements. If halves should come in anywhere, it should be on account of the speaking keys, but I have not claimed them. I prefer to leave it to any telephonic reader to estimate the value for himself. All the seven plug movements are slower by reason of the area to be covered, and one of them involves the selection of *some one* out of, say, a hundred, instead of *any one* (the nearest at hand) out of twenty or less. On the double-cord board, the only selection necessary is the second plug, to which the hand of the operator is guided by the cord of the first. Reply to 1 (b) is included in my second paragraph.

2. Simplicity of circuits. Mr. Jackson has overlooked a second contact on the engaged line of the single-cord board. It is in the unused spring jack. This narrows the question down to a simple one—the speaking-key contacts on an engaged line. It seems now that the only benefit conferred by the single-cord board is the absence of these two contacts.

Of course every contact is a *possible* source of trouble. On a well-designed switchboard every contact is also an aid to better working. "Troubles" of one kind may be largely avoided by a little trouble of another kind. In this respect let me compare the contacts on the two boards for the same number of subscribers. On the single-cord key-board there are 100 loose contacts open to dust and falling particles, on the double-cord key-board there are 80 spring-platinum point contacts protected from falling particles and so disposed that faults from "floating" dust are reduced to a minimum.

As a matter of fact, the trouble caused by keys is infinitesimal, whilst the advantages they confer are considerable. Their utility may be illustrated by reference to the diagram and description (October 24th), where there are none. The freedom from contacts is obtained at considerable cost. As speaking keys are so many branch lines by which the operator's outfit may be diverted easily and quickly to any circuit, an operator by their aid is able to "overtake her work." When there is only one means of access to the operator's instruments, as in the case of the single-cord board there are no such facilities, and she is consequently more "tied up," and putting through a number of subscribers in succession is a slower and more laborious process. Tapping a line in the one case is easy; in the other, difficult.

The "trouble" argument applies as much (perhaps more) to the cords. Mr. Jackson says that speaking keys might have been fitted. But surely if the argument is worth anything at all, it is an argument against the needless multiplication of either keys or cords. On a double-cord board the cords, and all the apparatus in their circuit, are auxiliaries only. In the single-cord board the cord is a link in the main line. It is, together with its contact, a weak link, and if it should be a broken link, the line is entirely disabled. This is bad for small exchanges, and especially bad in the case of small boards under private control. On the double-cord board a fault on cord, plug, or key does not interrupt a circuit. The afflicted set is placed *hors de combat* until it is convenient to repair it.

The greatest failing of the board to which I have drawn attention is confirmed in Mr. Jackson's letter, wherein he states that it is not usual to place two boards side by side, but to remove one board, and replace it by another as the subscribers increase. I will here define the third point which I suggested above. It is:—

(3) A switchboard with which an exchange is started should not need to be removed, but should be capable of being added to by other boards of the same kind until the exchange attains multiple rank.

Reasons which will justify changes and removals will occur to any exchange manager, but there are no reasons sufficiently good to establish, as a practice, such an unsound principle as removals with every increase of 20 or 50 subscribers. But for this correspondence I should have to apologise for expressing so well recognised a rule.

Mr. Jackson says it would be impossible to work 500 subscribers in a space of 10 feet. I enclose for your inspection a photograph of an exchange with ten 100-line boards. These boards are not 23 inches, but 17½ inches wide (the 23-inch board is a concession to appearances). I shall be glad to show the photograph, and give the name of the exchange to Mr. Jackson or anyone interested. This is an exceptional instance, but it goes to prove that the third point is not only theoretically safe, but practically attainable. The size of board to be adopted will vary considerably; 25 is a safe minimum and 100 a safe maximum, according to the varied circumstances which exchange managers have to consider.

In reference to the question of accessibility raised again in Mr. Jackson's postscript: the accessibility of the single cord board is nearly as good as the double for the same things. The reason why all the working parts can be reached from the back is, because there are no working parts anywhere else, and, as I have had to point out, it suffers in consequence. There are two accessibilities—one an operator's the other a mechanic's. If they do not happen to run together, it is so much the worse for the mechanic.

In reviewing the matter as impartially as one who has taken an active part in it can, I find that the numerous advantages claimed on October 24th are reduced to the two contact points. This advantage may be expressed by another point—a mathematical one. It has no magnitude.

Every switchboard is a combination of advantages and disadvantages which have to be carefully weighed. In the case of the double-cord board this has been done, with the result that probably nineteen-twentieths of the telephone world have adopted it for small exchanges. In the case of the single-cord board the balance may be easily struck, if the mathematical point be weighed against the very considerable disadvantages which have come out in the course of comparisons which I did not begin, but which I could easily continue in much greater detail.

J. E. Kingsbury.

December 16th, 1890.

#### Electric Light on Shipboard.

In my former letter on this subject a mistake occurred, which you pointed out by an asterisk and a foot note; the word should have been (*single wired*).

In regard to Mr. A. Campbell Swinton's remarks on my assertion regarding lead-covered wires, I may be permitted to explain that I treat the question of wires and their coverings from a rather different point of view than that taken by Mr. Swinton.

That the British Admiralty and others use lead-covered wire, and find it good enough for their purpose, is no proof, to my mind, that it is the best wire for ship lighting purposes.

Mr. Campbell Swinton, and those others who use lead-covered wires, admit that the lead acts simply as a waterproof covering; his letter amply proves this; it also admitted that the lead is not to be relied on for mechanical protection. Now I think a simple cable, having a continuous vulcanised rubber insulation, with a good braiding, comes quite up to the lead-covered cable, in so far as its being waterproof, and it does not require any more protection than the lead-covered wire. The question is this, whether is lead-covering or vulcanised rubber preferable as the waterproof in a cable for ship lighting? The lead covering is not an insulation; its object is to protect the insulation from water. The vulcanised rubber is the insulator in a cable, and can protect itself from water.

It is very well to get a cable from a maker guaranteed 500 megohms per mile, but after that you take, say, a hundred yards of it, cut the insulation away at a dozen places, make a joint at each, and cover them up again, soak it then for a week or two in sea water, joints and all, and then test the insulation. If the work is done by skill and with care, I admit that both lead and vulcanised cables will stand this test; but the tests would seem to make out that the lead covering is superfluous, seeing the vulcanised rubber can dispense with it, and the cost of making the lead joints is something extra.

I do not condemn lead-covered cables by any means. I think there can be nothing better for some purposes, and would use nothing else for long stretches of cables in tunnels, conduits, or underground work, where the covering does not require to be broken in many places, and joints are few and far between.

But in ship lighting, the unbroken lengths are short and the joints are many. Under these circumstances, my own experience is that a good vulcanised insulation, run in wood casings in the passages, saloons, and berths,

and in galvanised iron wire sheathing in the engine rooms, boiler stoke-holes, and shaft tunnels, and to the signal lights, is the best that can be done on ship-board, and so that the wire may be as short as possible, and the joints as few as possible, I prefer single wiring

Rankin Kennedy.

#### The Electro-Deposition of Copper.

Most of your readers will perceive, without any tedious elucidation on my part, how strangely Mr. W. Stepney Rawson misapprehends the drift of my letter. Because I say that, in considering a given case of electro-deposition from a general and abstract point of view (with the object of determining the expenditure of energy under any assumed conditions relative to *time* and *tank resistance*), we are bound to take the expression for energy  $C E \theta$ , rather than the equivalent

expression  $\frac{C}{n} \cdot E n \cdot \theta$  (with a concrete value for the

number,  $n$ , of tanks in series), he arrives at the conclusion that I am endeavouring to "justify the employment of a parallel system of electro-deposition." It is obvious from what I stated that, in regard to the arrangement of tanks in parallel or in series, there is no advantage apparent one way or the other until we come to practical considerations of convenience, &c., which may justify us in giving a concrete value to  $n$ .

In regard to Mr. Rawson's question, intended as a *reductio ad absurdum*, I am no authority in dynamo machines, but I think I may say that no large machines have as yet been constructed with so low a terminal P.D. as 1 volt. I have, however, some recollection of a machine by Siemens and Halske giving 1,000 amperes under a P.D. of 3.5 volts; and if a machine giving 3,500 amperes at 1 volt were really required (which it is not), I have no doubt but that it would soon be forthcoming. With  $n = 1$ , nearly the required quantity of work could be done with 21 such machines, or with a proportionately smaller number of machines of greater power.

Since I started the old *Electrician*, more than a quarter of a century ago, I have had much to answer for in the way of "leading articles;" and this may perhaps in some measure account for a tendency to use the editorial "we" in place of the egotistical pronoun. But I really must deny Mr. Rawson's soft impeachment in regard to this paper, for the simple reason that I have never written for it excepting over or under my own name. I am under the impression, moreover, that the editorial columns are entirely monopolised by the editors themselves. Although I consider Mr. Rawson's suggestion to be "rather bad form," I am personally not at all offended by it. But why, if things were otherwise than they are, should I not write even editorially for the REVIEW, provided I could get the Editors to accept my "copy"? Would Mr. Rawson suggest that I am not a fit and proper person, that I have interested motives, that I am biassed against himself, or the process in which he is interested? If so, I can only say that (having a few years ago spent a few pleasant hours in Mr. Rawson's company), any bias on my part would be in his favour, and that I have no interest whatever in depreciating any process for the electro-deposition of copper. Mr. Rawson, who seems to write with some bitterness, has apparently not noticed that we both, in my estimation, carried a point against the Editors in the matter of the number of working hours per week, and that my opinion as to current density allowable is decidedly favourable to the process above-mentioned.

Desmond G. FitzGerald.

**Electric Light in an Irish Factory.**—The whole of the immense buildings used by Messrs. Barbour and Co., thread manufacturers, Hilden, Ireland, have been fitted throughout with electric lighting plant. As showing the gigantic nature of this concern, one may mention that the buildings occupy a space of 35 acres, and over 5,000 hands are employed.

THE TELEPHONE.

THE recent expiry of the Bell Telephone patent has, we believe, hardly led to the brisk trade in telephonic instruments which many manufacturers anticipated ; possibly the lull may be only a temporary one, and it may cease when the second master patent, that of Edison, has lapsed, as it does in the middle of next year. It is not improbable, however, that the National Telephone Company may not consider that their claws have been completely pared down ; but that, as owners of comparatively recent patents dealing with important details, they have still plenty of fight left in them. The question as to licenses to be granted by the Postmaster-General for rival telephone exchanges is yet in abeyance, and until something definite is decided, but little can yet be done. There seems to be an impression abroad, however, that were action made free, formidable competitors with existing systems, in the shape of instruments for loud-speaking and long-distance working, would soon spring into existence. Those who imagine this must be profoundly ignorant of the laws which limit the possibilities of telephonic working, and which are as definite as those which limit the possibility of working submarine cables beyond a certain speed. We have more than once alluded to what is known as the "K R" of a telephone line, and it is surprising how very few seem acquainted with, or realise the exact significance of, the law therein expressed. We hear it glibly stated that telephonic communication, say, between London and Glasgow, a distance of over 400 miles, would be quite practicable, it is only a question of getting instruments powerful enough. Undoubtedly it is possible to speak that distance and to speak well, but it is not a question of instruments at all, it is a question of wire ; make the latter of copper and sufficiently heavy and the thing is done, but then will it pay ? What return on the total cost of a copper double wire, weighing not less than

400 lbs. (and probably 600 lbs.) per mile would be required to be remunerative.

Seeing the wide spread area over which the National Telephone Company have cast their network and the number of their subscribers, it seems difficult to see how the public will be induced to subscribe to a rival exchange, as it will naturally be very annoying for the subscribers to find that the persons with whom they desire to converse are not on their particular system ; even the inducements of a good service and a low subscription would hardly compensate for this.

In the matter of instruments it is whispered that the National Company are well aware of the unsatisfactory character of the transmitters used by them, but in view of the fact that the introduction of an improved form to even a few subscribers would lead to a general demand all round for the better instruments, and a consequent heavy outlay, they are unwilling to issue any other type than that in universal use, viz., the Blake pattern. Referring once again to long-distance speaking, it is probable that the commercial value of the new London and Paris line may inaugurate a new era in telephonic enterprise. It is difficult to forecast whether this will be a financial success, but the result of the experiment, commercially, and not scientifically speaking, will be looked forward to with great interest. We say "not scientifically," because the satisfactory working of the line, telephonically, we consider to be, beyond doubt, the margin beyond the practical "K R" limit, being amply sufficient to ensure success. At the same time, many will, no doubt, consider the experiment as an engineering triumph.

TEMPERED COPPER.

THE *Journal of the Franklin Institute* for December contains the report of a sub-committee appointed to decide upon the merits of the products of the Eureka Copper Company. The company claims to produce by

new, unpatented (and therefore undescribed) processes, copper castings free from blow holes, and to harden them without destroying their fibre or impairing their usefulness for electrical or other purposes. Chemical analysis showed that both tempered and untempered samples were commercially pure copper. Physical tests showed that the untempered had 20 per cent. and the tempered 35 per cent. greater tensile strength than the average shown by a U.S. Government report (1878). One hundred letters were sent out to users of the material and 53 answers received, "in which a definite opinion was expressed." Of these, five saw no difference between the tempered copper and other metal and alloys; eight had tried it for unsuitable purposes; six were against, and 34 in favour of, the claims of the makers. Amongst the 34 the use of the material for commutator brushes and segments was particularly prominent.

The committee recommend the award to the inventors of the John Scott Legacy Medal and premium, as they "believe that the claims of the applicants are substantiated by the experience of the majority of the parties using the copper, and also by their own investigations."

The prominence thus given to results of practical use by placing them as of first importance, and their own scientific tests as secondary, is somewhat remarkable. We agree fully with the committee as to the importance of practical use, but as the scientific tests are entirely authenticated, and the reports of the users appear to be irresponsible, we think that in this case the order of importance should be reversed. It is not a majority of users who substantiate the claims, but 34 out of 100, 47 either not replying or being indefinite in the expression of their opinions.

The advantages of such a material being considerable, there is no doubt its capabilities will not lack practical tests.

### MANNESMANN TUBES.

THE same journal contains particulars of tubes rolled by the method invented by Reinhard and Max Mannesmann. The method is of special use in making pipes designed to withstand heavy pressures. The process consists in feeding a solid heated bar of ingot metal between rolls which, while their axes are oblique to the axis of revolution, revolve both in the same direction. The metal of the surface of the bar thus acquires an increased motion in a spiral direction, and is drawn over its core, receiving, consequently, the form of a pipe. The pipe moves spirally forward, and the metal becomes still denser as its parts are spirally pushed and pressed. Much importance is attached to the spiral arrangement of the metal, apart from the advantage the tubes possess in presenting no lines of welding. The thickness of the pipe may be varied within wide limits from a bore of  $\frac{1}{16}$ th inch, and an outside diameter of  $1\frac{1}{2}$  inch to a bore 95 per cent. of the outside diameter. Whilst the description mentions only iron pipes as having been made, we presume, from the thin tubes above referred to, that the process is applicable to other metals.

### ELECTRICAL MINERS' LAMPS.

THE numbers and varieties of these lamps, which are continually springing up, is becoming legion, and one after another they drop into oblivion through having utterly failed to substantiate the claims that are made for them. One may generally judge of the value of these inventions by noting certain of the claims made for the information of the public, whom it is hoped to deeply interest in the matter to the financial benefit of the promoters. At the *Inventors' Institute* recently, a paper "of much interest" was read by Messrs. Gauzentes and Strong, on "A New Miner's Lamp and Primary Battery," the invention of the former gentleman. The following are some of the claims: "The metal which serves for the anode of energy is refined by a new and simple process, and allows us to obtain the maximum production of current without fear of rapid polarisation, which has up to the present proved the great obstacle to the employment of a direct source of electricity." This is the first time we have heard that polarisation took place at the anode of a battery; we were always under the impression that it took place at the cathode, but we stand corrected. The new fluid "can be manipulated without the slightest danger;" other fluids, of course, have proved highly dangerous, and have caused serious accidents, and no primary battery has in consequence been successful before the marvellous invention of M. Gauzentes was brought out. "Total suppression of all local resistance"—wonderful! The battery is guaranteed to last for five years; we wish the undertakers joy if they imagine that such a thing is possible. Cost of maintenance—5d. per 72 to 80 hours, all charges included; candle-power of lamp =  $\frac{3}{4}$ ; we have heard this sort of thing before. A portable table-lamp is stated to give "the happiest results," both as regards "immunity from fire and cheapness." Who that has seen electric table-lamps has not been struck by the absurd disproportion between the size of the lamp and the candle-power emitted. This has always been the case, and we venture to think is likely to continue to be so for some time to come. We do not mean to say that there are not very good points in the invention of M. Gauzentes. There are no indications as yet one way or the other; we have only assertions; but why bolster up what may be a good thing by absurdities? We fear, however, that M. Gauzentes has not made much advance on his plans of several years ago.

THE letter of the Chelsea Electricity Supply Company to the Vestry giving notice of its intention to discontinue the supply of electricity between the hours of midnight and four o'clock in the afternoon, in consequence of the fog, is, we think, a grave error. Although only a temporary measure, it seems to give more than a local colouring to the complaints which have recently been directed against this unfortunate company, and Mr. R. Chamberlain will now have additional arguments to support his contention that it cannot carry out its compact with its customers. To cut off light when it is most wanted seems to be a *reductio ad absurdum* of the most childish nature, and we can only think that the grounds for the complaints of Mr. Chamberlain and others are stronger than we had thought.

The Chelsea Company  
again.

## ON STANDARD WIRE RESISTANCES.

AT the recent meeting of the American Institute of Electrical Engineers a most interesting report was received from the Standard Wiring Table Committee dealing with its researches into the experiments made to determine the resistance of copper. We give the report as it was received, although it has since been somewhat modified by action of the institute in taking the soft copper standard mentioned instead of the hard copper standard.

*Preliminary Report of the Standard Wiring Table Committee in Regard to Matthiessen's Standard of Resistance of Copper.*

The council of this institute, at its regular monthly meeting, held December 3rd, 1889, appointed a committee "to formulate and submit for approval a standard wiring table for lighting and power purposes." The committee appointed consists of the following members of the institute: Thomas P. Conant, Dr. Louis Duncan, Prof. Wm. E. Geyer, A. E. Kennelly, George B. Prescott, jun., E. Wilbur Rice, jun., Prof. E. P. Roberts, Prof. Harris, J. Ryan, William Stanley, jun., Dr. Schuyler S. Wheeler, and Francis B. Crocker, chairman. This action was taken by the council with the object of overcoming, or reducing the great confusion which now exists in regard to the standards and constants of electric conductors.

At the first meeting of the committee, held January 10th, 1890, it was decided to confine the work at first to the three subjects of standard of resistance, temperature coefficient, and safe carrying capacity of copper, since these are of fundamental importance.

The subject of Matthiessen's standard alone is so confused and involved, and the discrepancies are so great between the best authorities that the committee has devoted its attention almost entirely to this subject up to the present time. After a very thorough investigation of Matthiessen's work with a view to ascertaining what his standard really was, by a sub-committee, consisting of Prof. Wm. E. Geyer, Mr. George B. Prescott, jun., and the chairman, the conclusion has been reached that Matthiessen's "mile standard" (one statute mile of pure copper wire one-sixteenth inch in diameter has resistance of 13.59 B.A. units at 15.5 degrees C.) is not the true one, although very commonly used. We consider the correct Matthiessen's standard, and the one in which he himself had most confidence, was the "metre-gramme" standard (resistance of pure hard-drawn copper wire, one metre long, weighing one gramme = .1469 B.A. units at 0 degrees C.). This has the disadvantage that it is expressed in terms of weight instead of diameter. It is, however, very much more difficult to get the exact mean diameter of a wire than to get its exact weight, as Matthiessen himself states. Furthermore, by selecting the most reliable constants given by Matthiessen, and corroborated by investigation and correspondence with the best authorities, we have, by calculation, converted this "metre-gramme" standard into a standard referred to dimensions and independent of weight, which is the form generally used. The various constants selected, the method of calculation, and the values deduced, are given in a table at the end of this report.

As to the fact that wires may be found which test 102 per cent of Matthiessen's standard, or even higher, we are of the opinion that this is no real objection, provided the value of the standard is definite and generally accepted. A standard which is not the highest attainable value may be even considered an advantage, since the average commercial wires will approximate to it more closely.

Although we believe the standard we recommend will answer the purpose temporarily, and probably permanently, nevertheless we think that if a thoroughly correct and complete redetermination of the standard resistance of copper could be accomplished it would be a benefit to electrical science and industry. Favourable

offers in this direction have already been received by the committee from the John Hopkins University, Cornell University, and Columbia College, and it is very likely that this redetermination may be undertaken.

This committee purposes next to take up the subject of the safe carrying capacity of wires. Matthiessen's standard recommended by this committee is: A hard-drawn copper wire one metre long, weighing one gramme ("metre-gramme"), having a resistance of .1469 B.A. units at temperature of 0 degrees C.\* From this standard we calculate, by taking the value 8.89 for the specific gravity of copper, that a hard-drawn wire one metre long and one millimetre in diameter ("metre-millimetre") has a resistance of .02104 B.A. units at 0 degrees C. This value is also given by Matthiessen.† Matthiessen's figures‡ for relative conducting powers are: Silver, 100; hard or unannealed copper, 99.95; soft or annealed copper, 102.21.

From these the resistance of hard copper is found to be 1.0226 times that of soft copper; therefore, the resistance of a soft copper wire one metre long and one millimetre diameter is .02057 B.A. units at 0 degrees C. From this the resistance of one cubic centimetre of soft copper is found to be .000001616 B.A. units at 0 degrees C. And the resistance of soft copper wire one foot long and .001 inch in diameter (mil-foot) is 9.720 B.A. units at 0 degrees C. Taking one B.A. unit as .9889 legal ohm, any of the above values may be converted into legal ohms. To find the conductivity of copper at temperatures other than 0 degrees C., Matthiessen's formula may be used:—

$$C_t = C_0 (1 - .00387 t + .000009009 t^2).$$

*Table of Values Based upon Matthiessen's Correct Standard.*

	B.A. units. 0° C.	Legal ohms. 0° C.
Matthiessen's standard metre-gramme, hard ...	.1469	.1453
Metre-gramme, soft ...	.1436	.1420
Metre-millimetre, hard ...	.02104	.02080
Metre-millimetre, soft ...	.02057	.02034
Cubic centimetre, hard ...	.000001652	.000001634
Cubic centimetre, soft ...	.0000001616	.000001598
Mil-foot, hard ...	9.940	9.829
Mil-foot, soft ...	9.720	9.612

Specific resistance of hard copper (1 cu. cent.) = 1634 (C.G.S. units).

Specific resistance of soft copper (1 cu. cent.) = 1598 (C.G.S. units).

Matthiessen's standard specific gravity of hard copper, 8.89.

Resistance of hard copper is 1.0226 times that of soft copper.

Resistance of soft copper is .9779 times that of hard copper.

Legal ohm is equal to .0112 B.A. units.

B.A. unit is equal to .9889 legal ohms.

After reading the report, Prof. Crocker, the chairman, added the following very interesting details concerning the practical side of the resistance question, and the information that he had been able to obtain as to the classical experiments on which our present standard is based. Prof. CROCKER said:—

"Of course, the derived values follow as soon as the fundamental standard is decided on, and the question, therefore, is, not what the derivations are, but whether the fundamental standard is correct; in other words, whether Matthiessen's 'mile standard' or Matthiessen's 'metre-gramme' standard is the more reliable. Now, the sub-committee has investigated this particular point with a great deal of care, and arrived at a very definite conclusion—that the metre-gramme standard was unquestionably the more accurate and the more reliable of the two, and that Matthiessen himself so considered it. Fortunately, after having decided this, we received a letter from Mr. Latimer Clark, who is one of the best authorities on this matter, and who was a contemporary of Dr. Matthiessen, in fact, he suggested to Dr. Matthiessen that he should undertake these experiments, so he is

\* *Philosophical Magazine*, May, 1865.

† *Philosophical Magazine*, May, 1865.

‡ *Philosophical Transactions*, 1864.

specially competent to express an opinion on this subject, and he agreed with our conclusions in every respect. We had already arrived at these conclusions, so his letter was simply corroborative. Mr. Latimer Clark's letter to the committee covered the subject very thoroughly and clearly, and I wish here to express our thanks to him for his kindness. There is, however, considerable confidence in the mile standard, and I think that it is simply that it has been used, and the fact that a mile and a sixteenth of an inch are more familiar values for the ordinary American and English engineer than a metre and a gramme, but the metre-gramme is just as capable of being transformed into practicable and common units as the mile and sixteenth of an inch. The necessity for deciding on some standard is more urgent than would be ordinarily supposed. This morning, for instance, in my ordinary professional work, I referred to two wiring tables issued by presumably competent persons, and both intended to be correct, and both being such as an engineer would use in his practice. One of these tables gave the resistance of No. 25 B. & S. gauge copper wire as 33.4 ohms per lb. at 75° Fahrenheit. The other gave it as 34.7 ohms per lb. at the same temperature. Now, there is a difference of 1.3 ohms in 33 ohms, which is about 4 per cent. In some cases it does not make very much difference whether it is 4 per cent. one way or the other, but 4 per cent. is a very considerable discrepancy, and in a great many cases it would make a very serious difference. For instance, I was figuring on 16 lbs. of wire, and it made a difference of almost 21 ohms. That is not only measurable, but it is a serious matter in some cases. I think that when two wiring tables that electrical engineers ordinarily use differ by 4 per cent., it is time to do something. I just happened to pick up these tables this morning. I did not do so with reference to this subject. I dare say if I looked for discrepancies I could find much greater ones. The adoption of this standard does not mean that every wire used for commercial purposes shall be 100 per cent. of Matthiessen's standard. There is no reason why an electrical engineer in his specifications should not require 101 per cent. if he considers it necessary, and I can think of cases where it might be necessary. On the other hand, it might be sufficient if the conductivity was 97 or 98 per cent. of the standard. It is simply necessary that we should have some definite value.

"The question whether any standard at all is necessary is a more important one; as it is not absolutely necessary to have a standard. We could simply say that one mil-foot or one cubic centimetre of the copper used for a certain purpose should have such and such resistance—in other words a certain specific resistance. But practical men have become accustomed to using Matthiessen's standard, and they seem to want a standard, and they will use one whether we want them to or not; such being the case I think it better to decide what Matthiessen's standard is. It certainly is commonly used. You see the expression in every book and almost every paper and specification, and as it now has no definite value—even though it is not used in the future, just simply to have it settled once and for all, I think it would be well to settle upon a definite standard. We feel sure that the institute will make no mistake in adopting this as Matthiessen's standard, and unless there is some particular objection to it which has not been brought out by our investigations, we hope the institute will do so."

Mr. Geo. B. Prescott, Jun., then added some further details of the committee's investigations and made the suggestion, which has since been followed, of taking the soft copper standard in preference to the hard. Mr. PRESCOTT said: "In making this report the committee has not thought it necessary to go into detail very much, and it may be interesting to members of the institute to know how this discrepancy in what is called Matthiessen's standard has arisen. In the first place, it is perhaps worth while to inquire why this standard was adopted in preference to any other. The reason was because Dr. Matthiessen made a series of

careful experiments to determine the resistance of metals and the variation of their resistance with changes in temperature, which extended over a great number of years and formed the basis of the work of the British Association, which decided on the practical standards. It seems that years before this British Association Committee undertook this labour various standards of resistance had been proposed by German, French and English electricians, and they were of all kinds, and among them was one proposed by Dr. Matthiessen, which was this 'standard mile.' There were no ohms in those days, and he made up a standard mile of this copper, and that was used as a unit in England for a long time. Later on, when the committee of the British Association had determined the value of the ohm in absolute units and had prepared practical standards, part of this committee tested the different standards that had been made in different parts of the world, including this standard of Matthiessen, and when they measured it they found that it was equal to 13.59 British Association ohms. Matthiessen never gave it that value; it was simply an arbitrary standard that he selected, because it was a convenient unit. Probably it was the size of wire commonly used in those days, so that really it never was a standard except in that sense. After Matthiessen's work was completed and published, Dr. Fleeming Jenkin, who was the secretary of the association, tabulated the results. Matthiessen's measurements were made with respect to weight and length, and also diameter and length. But his measurements of diameter were always very unsatisfactory, and finally the only measurements that he really relied on were those of length and weight. But he made a very great mistake, which he himself acknowledges in his reports, which was that he neglected to take the specific gravity of the actual samples that he experimented on, and the result, of course, is easily understood. Every sample of copper varies somewhat in its physical properties, and if you were to take one hundred samples of wire, and measure their resistances at a given weight and length, and then attempt to calculate the resistance from the cubical dimensions, you would find a difference, simply because there is a difference in the drawing of wires which changes their molecular constitution. Dr. Matthiessen neglected to take the specific gravity of any sample of wire that he tested, and the result is that we do not know to-day what Matthiessen's standard is, except in terms of weight and length.

"A further complication arose in this way, that Dr. Fleeming Jenkin, who, as I say, tabulated the results which Dr. Matthiessen obtained, made all sorts of derivations, giving the resistances in foot-grains and foot-mils, and metre-grammes and metre-millimetres—all by calculation. Of course, in converting from length and weight into length and diameter, he had to use specific gravity. He selected certain specific gravities. In his original table there are errors. Those errors have been copied. Other people have calculated tables from the standard mil unit, and, of course, they give different results, so when Matthiessen's standard is referred to to-day, there is a great deal of uncertainty as to which standard is meant. As a matter of fact, the statute mile standard is probably nearer the true resistance than the metre-gramme, for the reason that it gives a higher conductivity, and there have been any number of cases of wire being tested that had greater than 100 per cent. conductivity, and it was for this reason that seven or eight years ago I calculated a wire table, and selected this unit of Matthiessen's simply because it was the lowest, and agreed with some results that I had actually obtained."

Mr. GEORGE C. GROWER said: "I think there is a mistake made when hard copper wire is assumed as the standard and the resistance of soft copper reckoned from it. This takes for granted that there is a fixed ratio in resistance between hard and soft copper. But this ratio depends entirely upon the hardness of the hard copper compared with the soft. For instance, if you take large copper wire and have it as hard as you can get it, the conductivity would be almost as good as

soft copper, while in a small wire it would not be nearly so good. I have had as much as 8 per cent. difference between hard and soft copper made out of exactly the same stock on small wires. If we should make the wire very small, I dare say it would make still more difference.

"I agree with the committee that the metre-gramme standard is the more reliable, because whenever I have tried to make tests with diameter I could not get any sort of agreement among them; but where I take soft copper standard, no matter what the size of the copper is or anything else, so long as it is soft copper and from the same stock, I get almost the same result. But if you take hard copper for the tests, the tests will differ several per cent., according to the size of the copper. I think, for that reason, the standard should be of soft copper of a given length and weight."

Mr. CROCKER said: "It is perfectly correct as an abstract statement that soft copper is more constant in its resistance than hard copper. Hard copper can be made of almost any resistance up to several per cent. above soft copper. But soft copper is not Matthiessen's standard; it is precisely like the case of the foot. The English foot originally, I have heard, was the length of the King's foot. Well, now, at the present day, I think it is a little in excess of the average length of the human foot. But it does not make a particle of difference, providing it has a definite value, as it has, and providing a correct copy of the standard is kept in a safe place—it does not make any difference whether it is an inch longer or an inch shorter than the human foot. It has a definite value, and no one, I think, at the present time, would recommend changing the English foot, as a unit of measurement, to agree more closely with the length of the anatomical English foot. It is precisely the same with Matthiessen's standard. Unfortunately or fortunately, as you may look upon it, Matthiessen has promulgated a standard, and it has been largely, in fact almost universally accepted. Now all that is necessary is to adopt a definite value for this standard. It does not make much difference what it is, provided it is definite and generally accepted. Of course, in selecting a definite value, we want to select the best one, the most reliable one, the one that he himself considered most reliable, and the one that other authorities deem the best. So it seems to me that the mere fact that one standard or another approximates more closely to what the highest possible value is, or the fact that one or the other happens to be easier to determine in practice, makes no great difference, provided we get a certain definite standard or resistance for various lengths, weights, diameters, and kinds of copper. I think that all that is necessary is to free this subject from its great confusion by simply adopting a definite standard, and if that standard happens to be more correct than some other, so much the better; but even if it is not, it is very much better than confusion."

It is to be hoped that this report of the Standard Wiring Table Committee will receive the attention it deserves, as it certainly has gone far to straighten out the complex tangle into which some careless copying of constants has led. The report is both a judicious one and worthy of receiving general adoption.

## RESEARCHES IN THERMO-ELECTRICITY.\*

By Messrs. CHASSAGNY and H. ABRAHAM.

WE have already shown † that the electromotive forces of thermo-electric couples, the junctions of which are kept at 0° and 100°, may be determined within  $\frac{1}{10000}$ th of their value.

We must observe that when, as in our experiments, the equilibrium of electromotive forces is shown by a galvanometer of low resistance, this degree of accu-

racy is retained for the lesser electromotive forces given by these couples at the intermediate temperatures; the resistance introduced into the circuit of the galvanometer diminishing with the electromotive force to be measured, the absolute sensibility of the instrument increases, and the relative accuracy of the measurements thus remains almost constant.

We see, then, that thermo-electric couples employed as thermometers for registering very minute variations of temperature show the hundredth part of a degree between 0° and 100°, and they have this advantage over the ordinary thermometers that the smaller the variation of temperature is, the more accurately is it indicated.

In order to find the relation between the electromotive forces of the iron-copper couple and the scale of temperatures of the hydrogen thermometer, we measured these electromotive forces at different temperatures between 0° and 100°, one of the junctions being in ice, and the other in a bath of water stirred continually and placed in a regulating stove.

A thermometer placed beside the joint shows at each moment the temperature of the bath. The thermometer is of toughened glass, and was supplied by M. Tounelot, and the readings taken on this instrument were corrected and reduced to the scale of the hydrogen thermometer by means of the tables published by the International Bureau of Weights and Measures, where this subject has been studied.

We found, moreover, that the indications of this thermometer and those of a second thermometer of the same type, placed in the same bath, in no instance differed from one another to the extent of  $\frac{1}{100}$ th of a degree. The temperature of the baths varied very slowly, and these slight variations were indicated almost simultaneously by the thermometer and by the thermo-electric couple, the latter, however, always acting first.

A parabolic formula of two terms is quite incapable of showing the relation between the electromotive forces and the corresponding temperatures of the hydrogen thermometer, the discrepancies between the temperatures calculated by means of such a formula for 50° and 100° and the temperatures actually observed, amounting to +.12 of a degree at 25° and −.13 of a degree at about 75°. The following empirical formula, although still not representing the measurements with absolute accuracy, will give their values within  $\frac{1}{100}$ th of a degree, between 0° and 100°.

$$E_0^t = \frac{at + bt^2 + ct^3}{t + 273},$$

$$a = 10^{-3} \cdot 3.56604$$

$$b = 10^{-6} \cdot 8.3827$$

$$c = 10^{-8} \cdot 3.265$$

as shown by the following figures, taken from the same experiments:—

Value of  $E_0^{100} = .0010932$  of a volt.

Temperatures.	Electromotive forces.	
	Observed volts.	Calculated volts.
65.13°	.0007656	.0007654
32.49°	.0004043	.0004045

## THE OHIO STATE TRAMWAY ASSOCIATION.

THE opportunities for American electrical engineers to ventilate their ideas are quite in keeping with the general progress of the science. Not only do our American friends institute a number of "Conventions," purely electrical in their aims, besides attending the usual and frequent meetings of electrical societies and clubs, but they are now thoroughly invading the conclaves of tramway men, who, by force of circumstances, are all becoming amateur electricians and staunch supporters of the new motor. The Ohio State Tramway Association held its ninth annual meeting at Columbus, O., November 19th, when the President invited representatives of several electrical firms to describe to members the special features and advantages of each system. No papers were offered or read, but Mr. C. K. Harding, of the Harding Electric Railway Company, Atlantic, Iowa, opened the discussion by making reference to underground systems of distribution, in which, he regretted, the foreigner had taken the lead up to the present. The speaker passed on to a criticism upon overhead conductors, objecting to the unsightliness of wires and poles, the danger to other wires, interference with telephones, liability to damage from lightning, and the comparatively low voltage adopted, which is necessary for the safety of animate beings, but which does not offer the greatest economy and efficiency for distribution over large areas. In order to avoid these difficulties, Mr. Harding devised a closed conduit system which savours very much of inventions brought out in England at various periods. The following is the speaker's own description:—It should be understood that to preserve insulation you must exclude water, and to do that the conduit must be entirely closed, without slot or other opening through which the current is taken. In order to accomplish this result, I employ a tubular iron casing, in the top of which is a channel or flanged portion in which are insulated and supported the sections of the working conductor. These sections may be from 4 to 6 feet long, and extend an eighth of an inch above the surface, and are normally insulated from each other, the casing and the main conductor, which extends through the lower tubular part, and is entirely surrounded and embedded in the insulating material. In the end of each section of the casing or conduit there is an enlargement of the lower tube, which forms a junction box in which is located a small electro-magnetic contact, making a device which, when operated, connects its conductor section with the main or supply conductor. One end of the winding on the magnets of these contact devices is connected through a simple switch to the adjacent working conductor section, and the other end directly to the conductor section on the other side by means of this arrangement, and a second brush on the car. I employ a very small portion of the current to operate automatically the contact device, and bring the exposed sections of working conductor separately and successively into connection with the main insulated supply conductor when these sections are immediately under the car and protected by it. In other words, I get the current to the car through the series of insulated exposed sections which are fed from the main conductor as the car passes along, and are at all other times completely insulated from the wire carrying the current. By employing a derived circuit in multiple arc with the motor circuit, I am enabled to use a very small portion of the main current for the operation on the contact devices, and to make the magnets of small size and wind them with iron wire, thus making the construction of the contact-making devices a comparatively simple matter, and permitting them to be placed in a small closed cavity in the ends of the sections, where they will be readily accessible and interchangeable."

Mr. Curtiss, of the Short Electric Railway Company, stated that the greatest objection to electric railroading in its practical operation has been the one item of repairs. In one town, he was told by a gentleman con-

nected with the road, that the repairs last year amounted to \$1,100 per car. The Muskegon (Mich.) road, constructed by the Short Company, had been running for six months, commencing with five cars, and increasing to nine, but the repairs had not exceeded \$100 on all the electrical equipment.

Mr. C. A. Benton, of the Detroit Electrical Works, assured the audience that his firm had 21 cars running at Saginaw (Mich.), which have been in operation for 11 months, and the cost of repairs had not reached the sum of \$50.

Mr. W. J. Cooke, of the McGuire Manufacturing Company, advocated heavy trucks carrying electric motors, and he maintains that most of the trucks built at the present day were far too light, therefore not sufficiently strong. He did not mind carrying 1,500 lbs. in addition to what is the usual practice. Mr. Cooke also spoke of an electric heater, consisting of a ribbon running along the edge of the seat. The temperature can be varied to any degree by the driver who commands the switch which conveys the current from the trolley wire to the heater.

Mr. Bronnell, of the Bronnell Car Company, also dwelt upon constructive details of the cars. In most of the electric trucks the motors are located very close to the ground, underneath the car, which makes repairs very difficult, and involves laying up the vehicle during repairs to motors. It would seem that the better mode would be the use of a separate motor car of simple construction propelling the passenger car—in other words, he is in favour of electric locomotives.

## BRANLY'S EXPERIMENTS ON THE VARIATION OF CONDUCTIVITY UNDER DIFFERENT ELECTRICAL INFLUENCES.

AT a meeting of the Paris Academy of Science, held on November 24th, Monsieur Edouard Branly read a paper, in which he described some experiments upon the variations of conductivity observed in their metallic layers when subjected to electrical influences.

The layers of metal were prepared by spreading metallic dust upon a plate of ground glass or ebonite of dimensions 7 cm.  $\times$  2 cm., and then polishing with a burnisher. In the case of copper, a little tin was added to facilitate adherence. Such a layer is capable of a resistance which may vary from several ohms to several millions for the same weight of metal.

If a circuit be formed containing one of these prepared layers, a high resistance galvanometer, and a Daniell cell, only a very insignificant current is able to pass. An abrupt diminution of resistance, accompanied by a marked deviation on the galvanometer, is exhibited when electric discharges are produced in the neighbourhood of the circuit by the action of a small Wimshurst machine or a Ruhmkorff coil. This effect diminishes when the distance of the losses of discharge is increased; but it is easily observed, without special precautions when the distance is increased to several metres. By making use of a Wheatstone's bridge, it has been observed when the distance has been 20 metres.

Besides the behaviour of a thin layer of copper, that of similar layers of iron, aluminium, antimony, cadmium, zinc, bismuth, and several other metals were examined.

Check experiments were devised by Branly, and carried out, in which a capillary electrometer played an important part; but the results were in every respect confirmed.

Branly has examined the condition necessary to produce the observed phenomena, and with the following results:

It is not necessary that the circuit be closed, but the diminution of resistance is best produced if the metallic layer is bound by its extremities to the conducting wires.

The passage of an induced current through the layer

produces the same effect as that of a discharge in its neighbourhood.

When working with continuous currents, the passage of a strong current renders the metallic layer better able to transmit a full current.

The best results were obtained when, in these experiments, were substituted for the plate of glass and ebonite covered with metallic layers; what M. Branly calls "tubes à limailles," that is, tubes of glass or ebonite which have been treated with fine metallic filings mixed with some non-conducting liquid.

## THE ELECTRIC LIGHT IN AGRICULTURE.

[FROM A CORRESPONDENT.]

IN Hungary, where, until very lately, agriculture was almost the exclusive employment of the majority of the population, the electric light met with its earliest application in agriculture. It was used to thresh out the grain by night by means of movable light apparatus, driven by the locomotive of the steam threshing machine, in order to complete the threshing more quickly on large farms. Strangely enough, however, this arrangement, in spite of its great convenience, has still met with only a relatively small application. Baron von Steiger Münsingen has therefore taken the trouble to explain the advantages of threshing by the electric light on the basis of actual figures as obtained from his own practical experience. I think that I shall do many of your readers a service if I give the facts a wider circulation through the medium of your valued paper.

Where the farmer is limited to a certain number of labourers, and cannot procure more, it is no small convenience if they can be rendered available for other duties by a more rapid completion of the threshing. The economy of fuel is not to be despised, as the consumption is considerably less if the boiler is kept constantly hot than if it is let cool down, and steam has to be got up afresh every morning.

Night work is particularly advantageous for the possessor of threshing machinery, which can be hired out, as the machine can thus, in a single season, earn half as much more hire.

Much of this advantage can indeed be also secured by using more powerful machinery. But we must not forget, *e.g.*, an eight horse-power machine costs more than ten times as much as a lighting installation such as is needed for threshing.

In the work this season there was used an 8 H.P. threshing machine by Clayton and Shuttleworth, which had already served for eight seasons. The illuminating installation consisted of a dynamo, an arc light (in a bye-circuit) of 800 normal candles and their accompanying fittings. The cost of the entire installation, including the cart built at home, was 500 florins.

The first question was whether the engine, whilst working the threshing machine at full power, could supply at the same time the necessary power for the dynamo. My anxiety proved quite needless, as the requisite 1,400 rotations of the dynamo were obtained with the utmost ease without any higher pressure of steam. The engine, therefore, whilst working the threshing machine, had still a larger excess of power than was needed for the production of light.

The electric light installation connected with the threshing engine has been in action on my estate for 206 hours in 32 nights, or an average of 6.43 hours per night. The whole work effected this season in 922 hours was 751,900 kilos., or an hourly average of 815 kilos. Of this total there were obtained in 716 hours of daylight 589,000 kilos. or 822 kilos. hourly, and in 206 hours in the night by the electric light 162,900 kilos., or 790 kilos. hourly.

The ordinary hours of work in threshing begin at 5 a.m. and last, with half an hour off for breakfast, an hour at noon, and half an hour (time not stated), till 8 p.m., or 13 hours, which I may call a normal thresh-

ing day. If calculated into such days, the performance of the above-named plant would be 55.07 normal days by daylight, and 15.85 normal days by electric light, with an average result of 10.602 kilos. per normal day. Including Sundays and holidays, time lost by bad weather, removing the machinery, &c., there was a clear saving of three weeks effected by the use of the electric light.

If we suppose a constant light installation, working without disturbance, which is quite practicable, the proportion of the night work to the day work comes out more favourable. We have taken the normal day at 13 hours (from 5 a.m. to 8 p.m.). The night work from 8 p.m. to 5 a.m., is 9 hours, from which  $1\frac{1}{2}$  hour has to be deducted for lubrication and other stoppages, so that there remain  $7\frac{1}{2}$  hours of night work.

On using the night for threshing, changing the workmen of course at noon and midnight, the effective time for work would come to  $20\frac{1}{2}$  hours per calendar day of 24 hours. Of these, on account of the short summer nights, 6 hours would be by electric light and  $14\frac{1}{2}$  hours by daylight. The resulting gain of  $1\frac{1}{2}$  hour of daylight work results from the relay of workmen. We know that the average yield of an hour by night is 790 kilos., and that of an hour by day 822 kilos., so that the total yield of an 8-H.P. installation will be 16,659 kilos. per calendar day, as against 10,602 by daylight only.

Taking the present total yield of 751,900 kilos. of the above described installation as a datum, it appears that a threshing season of 45 calendar days, with the aid of the electric light, is equal to 71 calendar days with daylight alone. Hence, in the present case, there is the important economy of 26 days, or, in round numbers, a month.

As regards the remunerating character of the process, the author does not indulge in hypotheses of a threshing season without drawbacks, but takes the figures as resulting from this season's work, though it took place under unfavourable circumstances.

On the whole, 162,000 kilos. were actually threshed out by the electric light. If, in order to effect the work in the same time, this quantity had been threshed with a hired plant, it would have cost, on the usual hire of 4 per cent. in kind of the threshed grain, 6,516 kilos., or at the average price of 7 florins per metric cwt. on all the grain, 456.12 florins. Fuel and lubricants are not taken into account, as they remain substantially the same, whether the plant works without intermission, or if two work simultaneously. The lubrication for the dynamo has to be taken into account, as also the carbon rods, and the sinking fund for the lighting plant.

The consumption of lubricants for the dynamo for the entire 206 hours was  $1\frac{1}{2}$  kilo. of oil, of the value of 63 kreuzer. A pair of carbon rods, lasting 10 hours, cost 22 kreuzer, or per hour 2.2 kreuzer, or per metric cwt. 0.27 kreuzer, or for the entire season 4.53 florins.

As for the sinking fund, it may be reckoned in two manners. We may place the cost price of the installation of 500 florins opposite to the 450 florins earned by a hired installation. Next year, therefore, the plant would only have to earn 50 florins, and it would then work gratuitously, with the exception of the trifling cost for carbons and oil.

Or we may deduct from the cost price 20 per cent. sinking fund, and 5 per cent. interest, or, together, 125 florins.

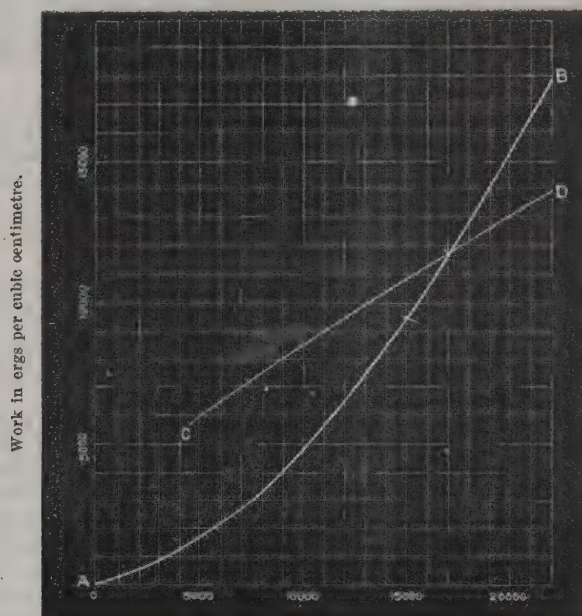

**Breakdown of Telegraphic Arrangements.**—Lord Salisbury was the victim of a breakdown in the telegraphic arrangements while delivering his speech at Waterfoot some days ago. The room in which the telegraphic apparatus was situated appeared suitable at first, but after the gas and stoves had been lighted it became so damp that the perforated paper ribbon used to work the Wheatstone automatic apparatus was rendered useless. So soon, however, as it became evident that the apparatus was unworkable arrangements were made for the report to be transmitted partly by hand signalling and partly by train to Manchester.

A SYNTHETIC STUDY OF DYNAMO  
MACHINES.

(Concluded from page 546.)

## X.—WORKING INDUCTION.

THE curve, A, B, in fig. 150, shows the work expended in carrying each cubic centimetre of the armature iron through a complete magnetic cycle at different degrees of induction, as explained in a previous article (p. 356). At first sight it might be imagined that a considerable benefit is to be derived from having a low working induction, but it must not be forgotten that for a machine of specified output, a low induction means a nearly proportional increase in the mass of iron in the armature. Taking a Gramme machine with the armature core pressed up to the usual induction of 17,000 C.G.S. per square centimetre, the ordinate to the curve, A, B, at the point represented by 17,000 on the line of

Induction per square centimetre.

FIG. 150.

abscissæ may be taken as representing the work done in magnetising and demagnetising the armature. If the radial depth of the armature core were doubled, the induction would be only 8,500, and the weight of iron would be nearly doubled, the exact increase of the latter depending, of course, on the relation of the radial depth to the diameter. However, assume it doubled for the sake of argument, and the curve, C, D, shows the energy expended for different degrees of induction. The lines cross at 17,000, as this is the normal induction for Gramme machines, C, D being drawn with the object of comparing the expenditure of energy for higher and lower working inductions with that at the normal. To draw this curve, all the ordinates of A, B are multiplied by the ratio of 17,000 to the induction for which they represent the energy expended, the assumption being made, as above stated, that the mass of iron is inversely as the induction. It will be observed that though the work expended per cubic centimetre for an induction of 8,500 C.G.S. is only 3,700 ergs as against 11,800 ergs for an induction of 17,000, the amounts of work expended for 8,500 and 17,000 respectively in armatures for similar outputs stand in the ratio of 7,500 to 11,800. It will also be noticed that for any given output there is only about 8 per cent. more power wasted in hysteresis at an induction of 17,000 than at 15,000.

This last statement shows that, for cylinder arma-

tures not much is to be gained by reducing the induction from the first to the second figure, while there is certainly something to be lost. If the radial depth of an armature is increased, it requires more wire to go round the core, which, consequently, has a higher resistance, while for series arc lighting, for which this class of machine is eminently suited, the armature becomes, by reason of the low induction, useless. For arc-lighting the armature should have an induction higher, if possible, than 17,000—in fact, the higher the better, since one of the essentials for good working is that the characteristic shall drop considerably in the vicinity of the working current, and that a relation shall be established between current and difference of potentials such that as the former increases the latter diminishes, and *vice versa*. In four-pole Gramme machines it is usual to employ a working induction of about 14,000 C.G.S. per square centimetre.

In armatures wound on the drum or Siemens principle, it is usual to work at an induction of from 13,000 to 14,000 C.G.S. if ample means of ventilation are provided. Where no means of ventilation exist, and the whole of the heat has to be got rid of by radiation from the external surface, the working induction is generally from 10,000 to 12,000. Here, for a machine of given output, it is obviously of no advantage to increase the induction, while something is gained by keeping it low. The diameter of the armature being settled with reference to the number and size of conductors, there is nothing, save as regards weight, to be gained by cutting away the interior of the plates. On the contrary, by making the central opening as small as possible, there is a reduction in the loss due to hysteresis, the magnetising force required for the armature is smaller, and these advantages are not counterbalanced, as in the case of cylinder armatures, by any increase in the resistance of the conductors. In machines of the drum type, having more than two poles, the interior opening in the armature core allows of good ventilation, and accordingly the working induction is generally between 13,000 and 14,000—very often the latter.

As regards the induction in the air gap, generally it will be found that this is very similar for both cylinder and drum machines averaging from 5,000 to 6,000 C.G.S. per square centimetre, though occasionally rising in the drum type of machine to 7,000. The number of ampère-turns which can be carried by the armature consistent with freedom from sparking, as influenced by the induction in the air gap and its dimensions, has been already discussed.

The induction in the magnets varies considerably in different types of machine. For annealed wrought iron forged bars 15,000 is usual, while in cast iron the induction is very much less, being generally from 7,500 to 8,000. Of the total lines of force which pass through the cross section of the magnets where the flux is greatest, only from 70 to 80 per cent. are utilised, the remainder choosing a path of their own outside the armature, and constituting a waste field. The magnitude of this field depends on the design of the machine, and the circumstances influencing it have been already discussed.

In penning these articles, an attempt has been made to place before our readers the latest considerations respecting dynamo designing. While we have been publishing them many important papers on dynamo construction have appeared, while several new designs of machines have been described and illustrated in our columns. Necessarily the simultaneous publication of these has narrowed to some extent the scope originally proposed for these articles, but that a large amount of ground has been gone over will be readily admitted by those of our readers who have followed the papers from the beginning. The one section which has not received attention in the present series, namely the regulation of machines, we find it advisable to postpone for the present, partially influenced by the above reason. But we trust that so far as we have gone our efforts have not been without benefit to our readers.

## AN ELECTRICAL LOAD EQUALISER.\*

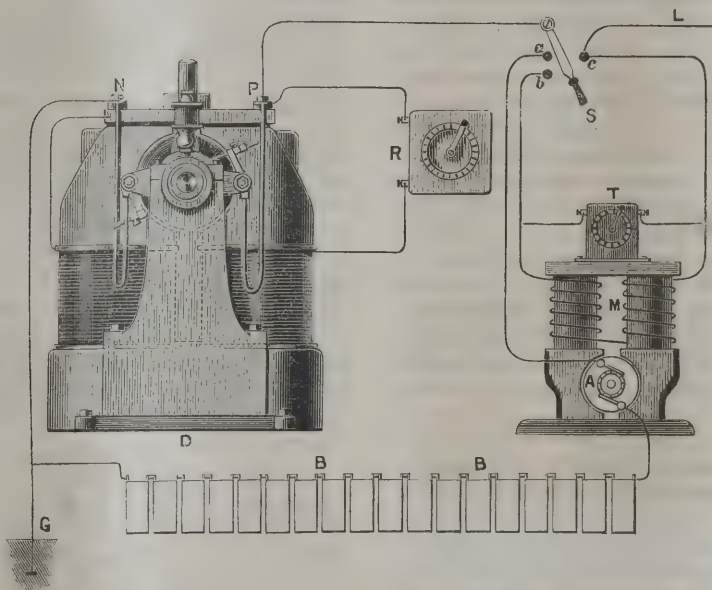

By C. O. MAILLOUX.

THE task allotted to the steam engine in electric railway work is not an easy one. It would indeed be difficult to contrive a more crucial test than such work affords of the regulating qualities and mechanical endurance of an engine. The load is incessantly undergoing fluctuations which are not only sudden, but extremely severe. An interval of a few seconds often marks the jump from light load to the maximum capacity of the engine, or else a sudden release from full load to no load. Yet, under these trying conditions, the engine is required by the electrical engineer to satisfy in turn and collectively the three important requirements of close regulation, great mechanical endurance and high economy. It is almost needless to say that these three qualities have not yet been reconciled under such conditions. In electric railway practice, it is not uncommon to find a 100 H.P. engine carrying an average load of from 40 to 60 H.P. The fact that the load is likely to jump up now and then to 100 or 120 H.P. makes this margin necessary, for without it, the first two qualities, regulation and endurance, could not be secured. As for the third quality, it is of necessity sacrificed. Even under this compromise the

wheel does in a mechanical way for the engine. It provides the circuit with a kind of reserve fund of energy that is ready to instantly appropriate any surplus of electric power when the load is light, or make up the deficit when it is heavy.

The method consists in connecting to the terminals of, and in parallel with, the ordinary generating dynamo, D, supplying feeder circuit or trolley line, L, a compensating circuit, including a series of storage battery cells, B, B, and the armature, A, of a small supplemental generator. The field magnet coil, M, of this small generator consists of a few turns of large wire similar to the series coil of a compound wound machine. This coil is not included with the armature in the compensating or branch circuit, but is placed in the circuit leading to the trolley line. Consequently, when the circuit switch, S, is thrown to the left, thereby connecting the dynamo to both points, *a* and *b*, and closing both the main and branch circuits, the current sent out to the trolley line, L, will pass through the coils, M, suitable means, such as a shunting rheostat, T, being provided, whereby the effectual ampère turns due to a given current may be adjusted.

The armature, A, of the small machine is driven at constant speed by power obtained from any convenient source, as, for instance, the same engine that drives the main dynamo, D. It might be driven by a separate

durability, as experience shows, is not by any means an assured quality. Practice is indeed drifting to the conclusion that a further compromise must be made to favour still more the second at the expense of the first quality, and engines of slow-speed types are coming into use. This change also favours the third quality incidentally, but only to a remote degree.

The question of economy in electric railway working is not altogether one of engine type or capacity for the particular case. The efficiency of an engine running light is zero; that of an engine overloaded and taking steam during the entire stroke is also very low. Between these two extremes there is a point of maximum efficiency, corresponding usually to the nominal rated capacity of the engine. If the engine can be worked at this capacity, and if fluctuations much above or below this load can be avoided, the conditions will no longer be incompatible with, but will become favourable to, efficiency. With a steadier, more uniform load, the problem of speed regulation of course vanishes, while that of durability becomes greatly simplified.

It was this reasoning which led the writer, some time ago, to devise a method of equalising the engine-load by electrical means, and of rendering the engine independent, to a great extent, of the fluctuations in power consumption on the trolley lines. The method aims to accomplish electrically for the dynamo what the fly-

engine, or by an electric motor supplied from the trolley circuit. This armature is made of low resistance, and capable of carrying a large current.

The cells, B, B, may be of any form, although the Planté type is preferable on account of its simplicity and its ability to withstand severe rates of charge and discharge without injury. These cells need be but of small capacity or only partially formed, since the storing capacity required of them is very small, as will be seen. The number of cells required will depend on the voltage of the circuit. For a 500-volt circuit, which is the usual standard in electric railway practice, a series of about 225 cells would be required. The facilities for adjustment are such, however, that the number of cells may be varied considerably without detriment. It will be seen from the connections that so long as no current is consumed on the line the armature, A, will have its field demagnetised. It therefore generates practically no E.M.F., and constitutes merely a dead resistance.

By the passage of current to the trolley line the field magnet coil, M, is excited and made to produce a definite amount of field magnetism. It is evident, therefore, that the E.M.F. of the armature, A, will depend altogether on, and will rise or fall directly with, the current consumed on the trolley lines. This E.M.F. is so "poled" as to add itself to that of the cells, B, B. It results that when there is no power consumed on the

\* *Electrical Engineer*, New York.

trolley line the voltage of the cells, B, B, will be so much lower than that of the dynamo, D, that there will be a large "overflow" of charging current into them. As the power consumed on the line, L, is increased, the armature, A, will begin to generate an E.M.F. that will raise the effective voltage of the battery and consequently reduce the charging current, until finally at a certain point it will stop altogether. If the current now rises above this limit, it will raise the effective voltage of the compensating circuit above that of the dynamo. Consequently the battery will now begin to discharge current into the circuit just as if it were another dynamo coupled in parallel with the main dynamo, D. When this point is reached, if the field magnet of the small machine is still much below saturation, the further increase of the current may raise the effective E.M.F. of the compensating circuit considerably higher than that of the dynamo. It might seem, therefore, that the dynamo, D, is likely to be over-balanced and converted into a motor.

There is another important factor that intervenes here, however, viz., the polarisation of the battery. It is well known, as one of the disadvantages of storage batteries, that their potential difference is diminished as the discharge current is increased, partly owing to their internal resistance and partly to the effect of polarisation, the latter being especially marked with heavy discharges. It follows from this that the effective voltage of the compensating circuit when the discharge begins, will not rise in proportion to the E.M.F. added by the armature, A, but at a rate which is slower the greater the current; consequently, when a certain current value is reached the rise in effective voltage will be much slower. If this does not suffice to limit the rise of E.M.F. made in the compensating circuit, the adjustments can be made to lower the saturation point of the field cores, so that the bend of the characteristic may correspond to a lower current. This can be done by suitably proportioning the iron in the field magnet cores; or, with a given machine, by varying the effective ampere-turns, by means of the shunting rheostat, T, the speed being changed so as to preserve the same total range of supplemental E.M.F. Thus it is seen that the rise of effective E.M.F. in the compensating circuit can be limited at any desired point.

If the limit is the same as the E.M.F. of the main dynamo, then the compensating circuit will supply about half the current required for the trolley line. If the limit is a trifle higher the compensating circuit will supply slightly more than half. If the limit be sufficiently high the compensating circuit will assume practically the whole load, and relieve the dynamo and engine.

It is not necessary, as might appear at first, that the field cores of the supplemental generator should be laminated, to make the apparatus sensitive and responsive to sudden fluctuations. Advantage, again, is taken here of the polarisation of the batteries. It requires a minute interval of time for a storage battery to polarise or depolarise. This interval will practically balance the time required for the rise or fall of magnetisation.

As a case illustrating the operation of the above method, let us take a dynamo of, say, 50,000 watts capacity, supplying a railway circuit at 500 volts pressure. Under present practice the average load put on such a machine would scarcely exceed 60 amperes, and the engine would be of about 100 H.P. capacity, if not more. Instead of this, an engine of about 80 H.P. would be used, and the average load would be made at least 90 amperes. The compensating circuit would then be so adjusted that whenever the current consumed on the trolley line would fall much below 90 amperes the main dynamo would overflow into the battery. If the consumption ceased altogether, for a brief instant, as so often occurs, the dynamo and engine, instead of running empty, would run at nearly the same output, the whole current being sent into the batteries.

As the current increased on the trolley line the overflow would diminish, and, at a little below 90 amperes, it would cease. Any increase above 90 amperes would cause the battery to discharge and help the dynamo.

The greater and the more urgent the demand for assistance the more promptly and liberally will the supply be given. Not only will the supply provide for the excess of current required above the 90 amperes furnished by the dynamo, but, as shown above, it may be made to relieve the dynamo itself either partly or wholly.

Let us now analyse the action of the compensating circuit. When there is no current on the trolley circuit the current sent into the batteries will pass through the armature, A, as if it were a dead resistance. When current is consumed on the line, however, the magnetic field becomes excited, and the charging current now operates the armature, A, as a motor. The amount of energy thus re-converted is not large, however, since the charging current is large only when the counter E.M.F., generated by armature A, is small, and *vice versa*. When the working current rises above the adjusted limit of 90 amperes the batteries begin to discharge, and the armature, A, then becomes a dynamo.

Let us assume that the load jumps up suddenly to double its average value, or 180 amperes, and remains so for five minutes. Such severe fluctuations are not infrequent, although they scarcely persist, as a rule, longer than from a few seconds to a minute. Let us assume that the compensating circuit will carry the excess of 90 amperes, making, at, say, 501 volts, an output of 45,090 watts. If we assume that the battery will so polarise at this rate of discharge that it cannot be counted upon for more than, say, 1.8 volts per cell, we have, as the available potential difference of the battery,  $225 \times 1.8 = 405$  volts. The armature of the supplemental generator will therefore need to supply  $501 - 405 = 96$  volts. The amount of energy which the supplemental dynamo must provide will consequently be  $96 \times 90 = 8,640$  watts. The battery supplies the rest, or  $405 \times 90 = 36,450$  watts.

If the same engine drives both dynamos, we see that a rise of 100 per cent. in the current load will only cause a rise of 20 per cent. in the output of the engine. The battery furnishes the other 80 per cent. If, however, we consider that the engine is likely to slacken its speed slightly when the fluctuation occurs, or if we adjust the supplemental dynamo to a slightly higher limit of E.M.F. the main dynamo, D, will be partly relieved of its own load.

In other words, the conditions can be made such that the main dynamo will carry, let us say, only 80 amperes, and the compensating circuit 100 amperes. The combined load of both dynamos will now be  $80 \times 500 = 40,000$ , and  $100 \times 96 = 9,600$ ; total,  $40,000 + 9,600 = 49,600$  watts, or only 4,600 watts, or 10 per cent. more than the average working rate of the main dynamo. The battery will supply  $100 \times 405 = 40,500$  watts or 90 per cent. of the energy required in excess of the average load.

The storage capacity required to compass such a severe and prolonged fluctuation is naturally a question of importance. A current of 100 amperes for five minutes represents a total of 500 ampere minutes, or  $\frac{500}{60} = 8.33$  ampere hours. Hence, if each cell has a

storing capacity of only 10 ampere hours, it will have margin sufficient for all contingencies. Even if doubled, the capacity per cell would still be only about one-eighth to one-tenth of the capacity of the cells used in storage battery traction. For a 50,000 watt dynamo the series of cells required would be equivalent in storage capacity to about one-fourth of the battery usually put into each storage battery car.

With the above method of equalising the load, the part assigned to the engine becomes wonderfully easy and simple. The engine no longer is required to anticipate and provide for jumps in the load. It no longer has the responsibility of keeping the current pressure steady, or its supply adequate. Its load becomes so nearly uniform, that the first of the three requirements noted in the beginning, close regulation, is no longer of primary, but is of remote importance, while the second and third are at the same time greatly facilitated.

The slow speed, double valve engine, whose superior economy is conceded, now becomes not only permissible, but eminently practicable. We must also bear in mind that this method further favours economy by materially increasing the working capacity of a given plant, obviating, as it does, the necessity for the margin required under the old way, to compass the fluctuations of load. The method is, it is evident, applicable to all systems of the constant potential description, and is adaptable to circuits fed either direct or by feeders. The method can be applied to any existing plant without difficulty.

On following the connections in the diagram it will be seen that by turning the switch, S, to the right, instead of to the left, the compensating circuit is entirely disconnected, and the plant operates in the usual way, leaving the engine to bear the brunt of any fluctuations in the power consumed. The method admits of being modified and applied in an indefinite variety of ways, which cannot be detailed in this space.

In conclusion, it may be noted that accumulators have been for several years used as equalisers or regulators in connection with incandescent lighting circuits. The compensating action thus obtained, however, is much limited in scope and degree. The battery, when unaided, evidently cannot begin to assist the dynamo until the latter has actually wavered perceptibly in potential; and anything like a severe rate of discharge would at once lower the potential below that of the dynamo itself. Hence, even though, in such cases, large cells are used, to reduce the internal resistance and polarisation to a minimum, the compensating action is useful only for compassing relatively minute and brief fluctuations. By supplementing the E.M.F. of the accumulators, as is done in the method of the writer, the action is rendered independent of the size of battery used or of the extent and degree of the fluctuations to be compassed. Not only this, but the action does not depend on the loss of E.M.F. of the main dynamo. In fact, as we have seen, the method has for one of its objects to obviate any fall of voltage at the dynamo terminals, while it will easily, if desired, produce the contrary effect, or raise the voltage as the load increases, the same as is done by an "over-compounded" dynamo.

## SOME FACTS CONCERNING GUTTA-PERCHA.

(Continued from page 737.)

THE investigations of the four official explorers—Seligmann, Wray, Burck, and Sérullas—agreed in the conclusion that if any of the more valuable varieties of the gutta-percha tree were to be perpetuated, cultivation must be immediately undertaken. These gentlemen differ, however, as to the name of the tree which ought to be propagated.

The *mayang taban dourrian*, of Singgaloungan, in Sumatra, was chosen by M. Seligman.

The *gutta taban mérah*, and the *gueutta taban soutra*, from Perak, in the peninsula of Malacca, were selected by Mr. Wray.

The *niatouh balam Tembaga*, from Ampaloo, Halaban, was considered the best by M. Burck.

M. Sérullas, owing to his having re-discovered the *Isonandra percha* or *Isonandra gutta*, of Hooker, in Singapore, naturally inclined to the propagation of this, the most valuable of all gutta-percha trees. No other *isonandra* (*palaquium* or *dichopsis*, the name matters little), combines the advantages possessed by this variety, whose gum has shown beyond all question or doubt the quality of stability. At the same time, it should be pointed out that other trees of the same species, found in various portions of Malaysia, and known under local names, such as those above-referred to, possess qualities not much inferior to those of the *isonandra gutta*.

In considering the regions natural to the gutta-percha

tree, M. Sérullas indicates Malaysia as the only district, owing to its climatic conditions, where the best varieties are to be met with. This question is one of great importance, for upon it depends the cultivation of this plant in districts to which it is not indigenous.

M. Seligman adopts as the limits of the home of the gutta-percha tree the fifth parallel on each side of the equator. M. Sérullas, however, disagrees with this opinion, and suggests that the isothermal lines at six degrees north and south of the intersection in Malaysia of the geographical and thermal equators confine the zone of the guttas.

If the thermal equator be followed from east to west, starting from the Celebes, it will be found to traverse the island of Borneo, the south of the Malay peninsular, the north of Sumatra, Southern India, the Gulf of Oman, crosses Africa from the Red Sea to the Gulf of Guinea, strikes South America at the Guianas, and crosses it through Venezuela and Colombia to the Bay of Panamá; in the Pacific it leans southward to nearly the Salomon Islands, and after skirting the north coast of New Guinea returns again to Celebes. Along this track, and beyond the limits of its Eastern abode, the gutta-percha trees are represented by the *payena* in Southern India, the *bassia Parkii* in Africa, and the *Mimusops balata* in Guiana, Venezuela, and Colombia.

M. Sérullas indicates various of the French possessions in the East as being suitable for the cultivation of the *isonandra*, and going further afield states that the islands of Réunion and Maurice, in the Indian Ocean, are well adapted for its propagation. Indeed, the gardens in the island of Maurice possess plants of the *Isonandra gutta*, of Wight, which have flourished in a remarkable degree.

It is worthy of mention that in the Island of Celebes, a region to all appearance admirably adapted to the growth of the *isonandra*, not a single variety is found of any value. This is accounted for by the fact that the flora and fauna are Australasian, not Malaysian. But, adds the author, it is beyond doubt that the *isonandra* could be easily acclimatised there. M. Sérullas treats at some length the various terms employed by the Malays in describing different gutta-percha trees. We will select a few of the words more commonly used:—

*Gutta*; *guétah* (Sunda); *gota* (Batak); *gueutta* (Malacca); *gatta* (Macassar); *guitta* (Dyak). Signifies something sticky, like gum or bird lime.

*Pertcha*, *pertjah*, *perdja*, or *peurtcha*. Means rag or strip of cloth, and describes appearance of those gums which, previous to treatment in hot water, look like rags half reduced to a pasty semblance and hard pressed.

*Balam*; signifies a plant giving a milky sap; *Mayang*, the way certain flowers grow; *Kayou*, a certain wood.

*Taban* or *Teban*, though not really the same words, are used to describe a tree of good appearance, one worth cutting down, and are employed to describe a gum of first quality. *Tchaier* signifies liquid, and is applied to gums which coagulate slowly, and are therefore of little value for telegraphic purposes.

*Boucou* or *becou*, knot, lump, or ring, and is descriptive of those gums which coagulate quickly, forming a sort of excrescence at the incision made in the bark.

The two best varieties of gum are distinguished by a difference in colour, one called *mérah* (red) and the other white, known as *soutra* (soft or silky), so as to separate it from another white (*pouteh*) variety, but which is not good enough to be classed as *becou*, and is better than the *tchaier*.

The leaves also have their various descriptive terms. *Tembaga*, coppery, from the colour of the underside; *Tumba*, lance, from the shape; *Dourrian*, from the resemblance to the leaf of the fruit tree of that name. These are all indicative of good quality.

From M. Sérullas's statements, it would appear that a certain gum may be described as a sticky substance coming from a plant which gives a milky sap, produced by a tree of first quality, which flowers in a particular manner, the underside of whose leaves is coppery.

coloured, and whose gum, of a red colour, hardens quickly, or otherwise. Add to these definitions the innumerable names invented by the natives to satisfy the insistence of travellers who desire more precise information, and the difficulty of accurately discriminating between the varieties of percha, can be understood.

The method adopted by the natives of collecting the gums is far more disastrous to the good varieties of trees than to those of inferior quality. In the case of the latter, the sap coagulates but slowly, and an incision made in the bark allows a flow of some hours; a sufficient quantity can be thus collected without having resource to the felling of the trees. With the best kinds it is otherwise; the sap hardens almost immediately, and the incision is speedily closed, allowing but an infinitesimal amount of gum to exude. The plan pursued with these trees is as follows: A scaffolding is raised close to the tree about to be cut down, so as to support it in an inclined position when felled. This having been done, all the branches are lopped off except the lower portions of the larger ones. Incisions are then made completely round the trunk, commencing at the higher part, each about three-quarters of an inch broad, and at about 18 inches apart. It is evident that an enormous waste of gum takes place, for the bark remains untouched between the incisions. From the younger branches of a specimen *M. Sérullas* saw cut down, he obtained fifteen times greater a quantity of gum than collected by the natives from the trunk and large branches, and from the leaves at least twenty-two times that amount.

After the gum has been collected, it is immersed in hot water, kneaded several times, and finally taken out of the water at the end of five or six minutes. It is then spread in very thin transparent sheets. The mixture of other gums, of bark, wood, and stones, takes place subsequently, when the gum is reboiled for this purpose, which is effected in the proportions necessary in the particular case.

A popular error with regard to the Dyak collectors of gutta-percha is the superstition imputed to them of looking upon the period of full moon as the only proper time for collecting. As a matter of fact, says *M. Sérullas*, the period considered by them as the best is immediately after the rains, when the sap runs more freely. A curious circumstance connected with the *locale* of gutta-percha trees, and the observation of which frequently assisted *M. Sérullas* in his search for them, is the fact that where they grow no leeches are to be found, though the immediate vicinity, and the forest in every other direction, may actually swarm with them.

We will not follow *M. Sérullas* in his strictures upon the erroneous information as to the varieties of gutta-percha, the methods of collecting, the yield of sap, &c., published by various travellers, among whom *Oxley*, *Lingard*, *O'Rorke*, and *Collins* are mentioned as principal offenders. The matter is of a certain interest, but occupies too much space. Briefly stated, it would appear that limited observation, imperfect acquaintance with the locality, and a too ready acceptance of native statements, together with the confounding of the methods used in the collection and preparation of india-rubber with those adopted in the case of gutta-percha, may account for many of these errors.

Nor have we space in which to transcribe the author's remarks upon the conditions governing the *Isonandra* in a natural state, or on the question of transporting young plants to a distance from their native forests.

In *La Lumière Electrique*, of December 13th, these matters will be found fully set forth. We may, however, quote, as more particularly interesting, certain observations. It appears that the stumps of gutta-percha trees, after the trunks have been cut down, invariably show a speedy and vigorous growth of buds and shoots. This of course only applies to forests untouched by fire. On several occasions, *M. Sérullas* had the opportunity of observing the wonderfully rapid and healthy growth of cuttings under purely accidental circumstances. In one of these cases the cutting happened to be the trunk of a tree thrown across a stream, and

forming portion of a bridge. As to the transport of young plants, the operation does not seem to have been so very difficult—warmth, shade, and moisture, their principal requirements in their native forests, appear, together with a sufficient protection of the roots, to be the chief essentials.

(To be continued.)

### THE NEW ELECTRIC "MOOTER,"

AS DESCRIBED BY BIDDY M'CLURE IN AN OHM-LY EPISTLE TO  
"A FRIND IN THE OULD COUNTRY."

(An electric motor has just been set up in a Brooklyn hotel for washing dishes.—*Daily Paper*.)

FORNINST the recait av this bit av a letther  
Fram your dear furrin frind, lone Biddy M'Clure,  
I'll just mintion me cowl an' me pay is aich betther  
Since I wint for me misthress, an' thin for the door;  
Shure meself cudn't stay wid her, she had such a way  
wid her—

Och! the month I was there was the tarrible jant!  
So, musha! I sacked her, an' wid me characther  
Crassed over the wather to Brookline beyant.

Good luck to her timper! no less to the bottle,  
By raison av which the same fell on my pate!  
For by the same token, I'm now in a hotel,  
Wid the misthress loike honey, her tongue is that  
swate,

Och! it's here the work's aisy, acushla! the lazy  
Colleens, shure they throubled the misthress a dale,  
Till nothin' wud suit her but to sind for a *mooter*  
For clanin' the dishes up affther aich male.

To describe it, acushla, 's beyand me—the sorra.  
The loike in ould Oireland iver was sane!

Av yez putt a windmill in a washtub, begorra  
There's a thrue-spakin' fortygraph av the machane!  
Arrah! what wid the splashin' av wather an' smashin'  
Av chinie that iligant mooter did make,  
I wint undher the table, entoirely unable  
To do half av me work for the howl av a wake!

Av ye ax *what compels it*, shure a saycret that same is  
As meself ud be proud wid me own frinds to share;  
But it isn't convaynient to spake what the name is  
Wid the spaich av the counthry so furrin an' quare.  
Shure, ye'll know quoite enough whin I say that the  
shstuff

Comes up through a hole in the tap av the flure,  
An' av it's wance shpilt, tare an' ages! it's kilt  
Entoirely thin is poor Biddy M'Clure!

But by this an' by that! it's meself won't decaive ye—  
I'm aloive, an' its marrit I'll soon be to Pat:  
Och, a mooter, alanna, 's a foine thing to lave ye  
Convaynient to do a bit coortin' an' that!  
For while wid the clanin' the mooter was strainin  
Up shteps a foine paler wid helmet an' shtick;  
Says he, "Och, ye craythur! yez two lips is swater  
Than suggar!" says he—"let me tashte thim, avick!"

Thin forninst your recait av this bit av a goster,  
Av the mooter plays thricks, shure your Biddy'll be  
dead;

But av it behaves, an' me Pat's no imposther,  
Thin praise to the Vargin! meself will be wed.  
Wid Pat at the windie, an' this divil's own shindie,  
Och, whirra! I'm ready to drop on the flure!  
So whether I'm baried, or dacently married,  
It's the mooter as done for poor Biddy M'Clure.

*Ariel.*

**Electric Light in Liverpool.**—A petition has been signed by occupiers of a certain district in Liverpool, requesting the Watch Committee to grant to the Liverpool Supply Company the necessary authority to enable them to lay electric lighting mains.

## TELEGRAPH COMPETITION IN THE WEST INDIES.

THE West India Islands, once the scene of a thriving commerce, the resort of an energetic and wealthy community, have, during years of adversity, gradually sunk to a position not far removed from that lowest of all conditions—a negro's paradise. Fallen from their high estate, they are to-day chiefly associated with such petty transactions as the production of swizzle-sticks and guava jelly. The decadence which has overtaken this erstwhile prosperous region—we speak more particularly of the British possessions—and the hopeless stagnation into which affairs have drifted, combine to isolate these islands from busier communities, and fully justify the application of the words “the world forgetting by the world forgot.”

All branches of industry seem to be pervaded with the lethargy resulting from years of inactivity, and the necessarily consequent indifference to progress and improvement has had such a widespread influence, that its effects have been evident in the paralysed condition of even telegraphic enterprise. We do not refer to the management, so far as efficient service and suitable tariffs are concerned, of that association which for nearly twenty years has held undisputed sway, but rather to the weakness and inactivity it has shown in allowing its opportunities to be irretrievably lost, and to the prolonged indifference in the conduct of its affairs, and the utter absence of prevision which have invited opposition schemes.

For a great change in the situation has recently taken place. This typical sleepy hollow, and its Rip van Winkle have been awakened to the fact that a French syndicate has discovered what others failed to appreciate, that the West Indies still offer a field to telegraph enterprise quite worth the cultivating.

This association, the *Société Générale des Téléphones*, founded in 1881, with a capital of 25,000,000 francs, was the prime mover in the establishment of the new submarine telegraph communications in the West Indies; and it is the chief factor in the organisation of the two companies, the *Cie Télégraphique des Antilles* and the *Société Française des Télégraphes Sousmarins*, whose names are more directly associated with the new cables. The first mentioned of these two companies was formed in 1884, with a capital of 200,000 francs, subsequently increased to 450,000; the second was founded in 1888, with a capital of 5,500,000 francs, afterwards increased to 11,000,000 francs.

In reviewing the work completed, in progress and contemplated, of these companies, we may neglect the *Compagnie Télégraphique des Antilles*, on account of the insignificance of its property. Before entering, however, upon a discussion of the aims and circumstances of the *Société Française des Télégraphes Sousmarins*, it will be necessary to revert, for a moment, to the *Société Générale des Téléphones*.

For many years the French Government has sought, whenever possible, to foster the manufacture of submarine cables in France, and to encourage French companies in submarine telegraph enterprise. The telephone company had become the proprietor of the well-known works of Rattier, at Bezons, near Paris; but the inland situation of this factory made it ill adapted for the manufacture and shipping of any considerable lengths of cable. With the view of meeting the wishes of the Government, and considering the probability that the telegraph companies, its *protégés*, would, in the course of time, largely extend their systems, the telephone company cast about for some seaport on the French coast suitable for the erection of a cable manufactory, and affording the necessary accommodation for cable ships. After the examination of several localities, Calais was finally determined on, and the factory at that place, immediately commenced, is now rapidly approaching completion.

An examination into the conditions attending the present development of telegraphic communications in the West Indies would appear incomplete without some

reference to the concessions obtained by the *Société Française des Télégraphes Sousmarins*. The older ones, relating to cables already laid between Cuba, Haiti, Santo Domingo, Curaçao, and Venezuela, need not be recapitulated: we shall therefore confine ourselves to the more recent concessions:—

**Martinique—Guadeloupe (laid).**—Concession dated 7th June, 1889. For 25 years. Exclusive rights to land and work submarine cables. Annual subsidy granted by each island of £2,000.

Note (1). The agreement between the French Government and the West India and Panama Telegraph Company with regard to Martinique, expired on the 31st December, 1889; that relating to Guadeloupe terminates on 1st January, 1895. (2) The new concession stipulates that these islands shall be connected with some point on the present system. This in all probability will be either Santo Domingo or Puerto Plata, in the Republic of Santo Domingo. The payment of the subsidies must naturally mainly depend upon the establishment of this connection, by means of which the southern portion of the system is brought in communication with Cuba.

**Guadeloupe — Marie Galante (laid).** — Concession dated January, 1890. For 25 years. Annual subsidy granted of £400.

**Cayenne (French Guiana).** (To be laid shortly).—Concession dated 11th October, 1889. For 25 years. Exclusive rights of traffic. Annual subsidy granted of £4,000.

Note.—The concession stipulates that Cayenne shall be connected directly or indirectly with either Martinique or Guadeloupe.

**Paramaribo (Dutch Guiana).** (Laid 1890.) Concession dated 18th September, 1889. For 20 years. Exclusive rights for landing and working cables between Surinam and Cayenne, Venezuela, Curaçao, Haiti, Santo Domingo, Cuba, Martinique, Guadeloupe, and New York. Annual subsidy granted by Dutch colony of £2,400.

**Brazil — United States.** — Concession dated 10th January, 1890. For 35 years. Exclusive rights for transmitting, by one or more cables, directly or indirectly, all telegrams addressed to the United States which may be handed to the Brazilian Government telegraph stations, and exclusivity for all cable communications between Brazil and the United States.

Note (1). The Brazilian Government undertakes to afford the French Company special facilities for the interchange of traffic. (2) An earlier concession had been granted to the *Pedro Segundo Telegraph Company*, which, in an agreement with the *Société Française*, bound itself to connect this company's system with Brazil, and to obtain landing rights for it in the State of New York. (3) The concession granted to the *Pedro Segundo Company* lapsed owing to non-fulfilment on the part of the company.

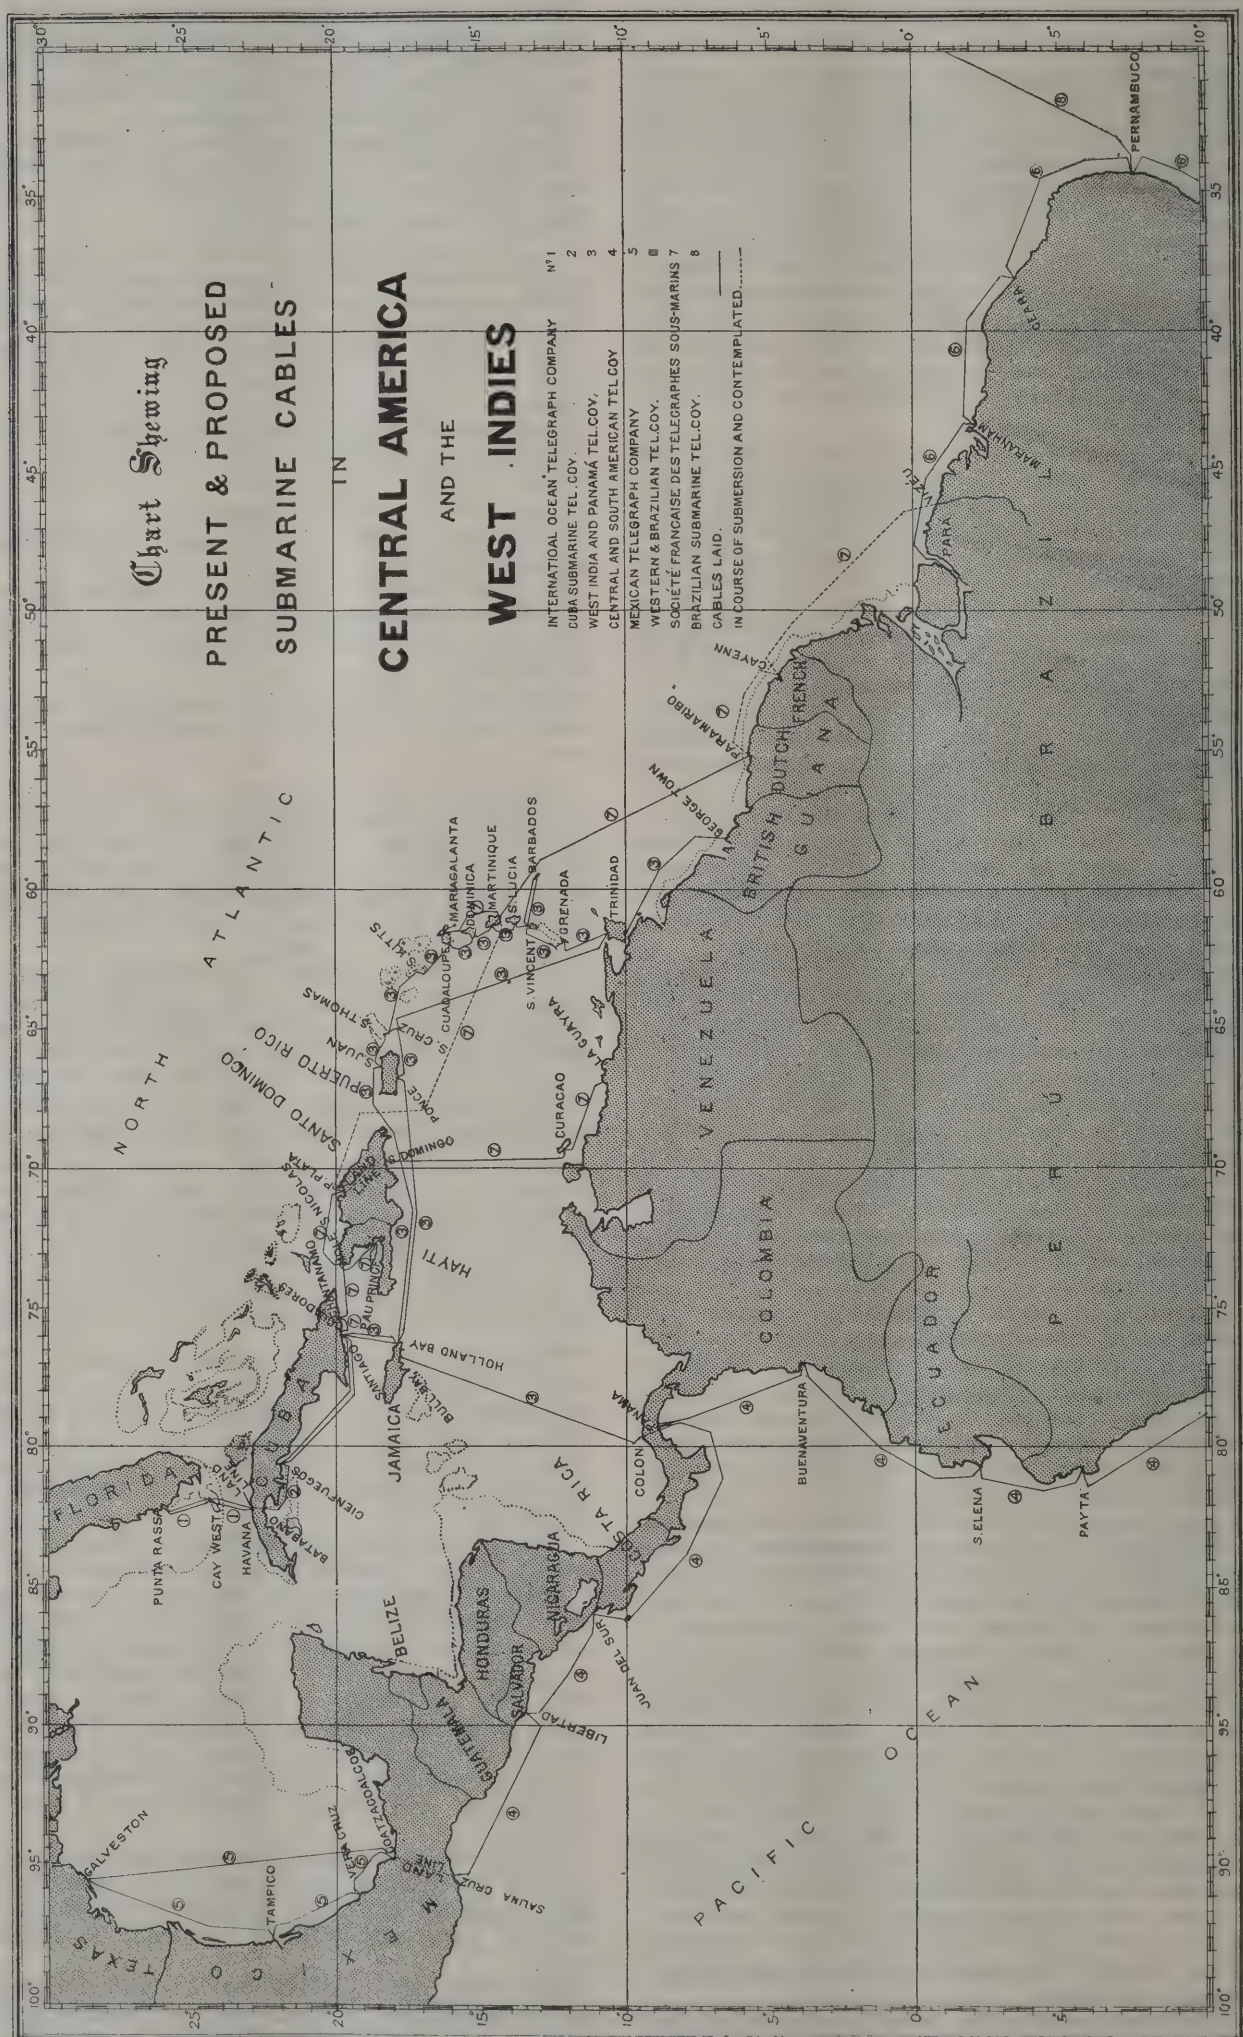

**Vizeu (Brazil)—Cayenne (French Guiana).** (To be shortly laid.) This section is included in the above-mentioned Brazilian concession, which contains a clause to the effect that Vizeu, in the province of Pará, shall be connected to the French Company's system, by means of a submarine cable, on or before the 26th August, 1891.

**Mole St. Nicolas—Port-au-Prince (Haiti).** (To be shortly laid.) Concession dated 28th June, 1888. For 60 years. Exclusive rights for landing and working cables. Purchase of cable, by Haitian Government, by instalments extending over 2½ years, for £24,000.

**Haitian Land-lines.**—Concession dated 14th April, 1890. For 60 years. Exclusive rights in Haiti for constructing and working land-lines. The Government guarantees an annual interest of 8 per cent. on the capital expended in constructing certain lines, on the basis of £68 as cost per kilometre of line constructed.

**North Coast of Cuba.**—Concession granted by the Spanish Government for connecting, by means of submarine cables, the town of Santiago de Cuba with the principal ports on the north coast of the Island of Cuba.

**Santo Domingo.**—The exclusive rights for landing and working cables in the Republic of Santo Domingo expired on the 1st of August, 1890. A prolongation of these rights up to 1st August, 1892, has been obtained

through the Société Générale des Téléphones, by the payment of £12,000.

The foregoing brief sketch, although not altogether complete, sufficiently indicates the position held by the French company; it is still undecided what route will be followed by the cable, or cables, necessary to connect Martinique and Guadeloupe with that portion of the system which gives an outlet from the West Indies *viâ* Cuba. The connection might be made either at La Guayra, at Curaçao, or at the port of Santo Domingo; in each of these instances the land-lines across the island of Santo Domingo would become a part of the main system. Or the cable, as will probably be the case, might be laid direct, from either Martinique or Guadeloupe to Puerto Plata, on the north coast of Santo Domingo, where the existing cables between that port and Cuba afford the desired communication.

The chart which accompanies this article will give a better idea of the situation than could possibly be obtained from a mere verbal description, and one cannot but wonder, on inspecting this chart and reviewing the programme of the French company, how it is that they have been allowed to occupy certain coigns of vantage.

A study of the circumstances would undoubtedly lead one to assume that the proper course for the company, which during nearly 18 years prior to the advent of the new undertakings, had held in its own hands the undisputed possession of the entire telegraphic communications in the West Indies, was to have secured itself in every feasible manner from the possible attacks of rival enterprises. The necessary precautions, however, were neglected, the opportunity was allowed to pass, and the Société Française, by establishing itself in Cuba, Haiti, Santo Domingo, Curaçao, and Venezuela, by ousting the West India and Panama Company from the islands of Martinique and Guadeloupe, by acquiring possession of the communications with the French and Dutch Guianas, and by securing an entry into Brazil, has obtained a permanent footing, not, indeed, without a struggle, in what should have been the elder company's reservation.

The Cuba Submarine and the West India and Panama Companies, awakened too late to the gravity of the situation, vigorously opposed the landing of the French cables on the island of Cuba, and for some time succeeded in hindering the opening of those lines to the public, maintaining that the wording of the concessions granted by the Spanish Government distinctly included exclusive landing rights in Cuba. On the advice, however, of the colonial section of the Council of State in Madrid, a Royal decree was promulgated authorising the French companies to land their cables in Cuba. The decree was dated January 17th, 1889, and the lines between Haiti and Cuba were opened for international traffic on February 7th of the same year. We imagine that the French company has, for this decision in its favour, in a great measure to thank the feeling, which of late years has become very noticeable in Madrid, that the West India and Panama Company has not fulfilled its engagements, nor adhered to the intention of the concession granted it in 1868. It is not our purpose, at least for the present, to discuss the merits of the case, but some mention of the circumstances seems necessary, more particularly as this very cable between Haiti and Santo Domingo is the keystone of the position, so far as the West India and Panama Company and the French Association are concerned.

The French company has secured, either by its own concessions or by alliance with friendly associations, cable communication between Cuba and Brazil; a new route between South America and the United States and Europe has thus been opened, and the stations on this new line will have duplicate communications with the outside world. Although this advantage is great, it is somewhat diminished by the fact that the Société Française depends, at present, for an outlet upon companies which have hitherto not shown themselves very favourably disposed towards the new enterprise.

At the Cuban extremity of the French system, com-

munication with North America and Europe is obtained through the Cuba Submarine Company's cables along the south coast of Cuba, and the International Ocean Company's lines between Havanah, Key West, and Florida: at Vizeu, the Brazilian termination of the system, a route to Europe is opened either *viâ* the Brazilian Government land lines to Pernambuco, or through the Western and Brazilian Company's cables between Pará and Pernambuco, at which latter place the Brazilian Submarine Company's trans-Atlantic cables terminate on the South American coast.

How much importance may be attached to the concessions granted to the French company for the cable along the north coast of Cuba is yet to be seen; under existing conditions such lines could only serve as local feeders to the general system, and the French company may have to push on its connections from its West Indian system, either direct to the United States, or may even be compelled to seek an outlet *viâ* St. Pierre, Miquelon, which place is directly connected to France by a transatlantic cable.

Far more menacing, however, is the position of the Société Française in the extension southwards of its cables. We refer to the circumstances which have permitted this association to continue its lines from the Guianas to Brazil, and it seems a very extraordinary omission that the gap between Demerara and Pará has not long ago been bridged over with some efficient means of communication. It is manifest that such a connection would have been most advantageous to the West India and Panama Company, and some exceedingly strong reasons must exist, other than difficulties in obtaining concessions, for neglecting so important a link. Perhaps the presence on the board of the West India and Panama Company of directors of the Western and Brazilian, and Brazilian Submarine companies, may in some measure, account for what may be described as remarkable apathy. We will not dwell, however, on this more personal portion of the subject, since it does not come within the scope of this article to discuss why, or how, an individual can attempt to serve two masters whose interests appear to be diametrically opposed.

An attempt was made in 1874 to connect Brazil with the West Indies. Cables were laid between the Guianas and Pará by the long defunct Central American Telegraph Company; but as a means of communication these lines were literally ephemeral, lasting but a day. It is to be remarked that the West India and Panama Company, at the time, or shortly after, these cables were laid, entered into negotiations for their purchase, if, indeed, it did not become actually the proprietor of them. It is also worthy of note that the arrangements entered into between the West India and Panama Company on the one hand, and the Brazilian Submarine and Western and Brazilian Companies on the other, seemed to result in the utter collapse of the Central American cables. We are ignorant as to what attempts, if any, may have been made to repair these cables, but this much is certain, they were speedily abandoned.

In considering the results which are likely to attend the establishment of the cables of the French companies, certain important factors must not be lost sight of.

The concessions granted by the Brazilian Government to the Société Française will hinder, for the time being, the organisation of a completely independent cable route between Brazil and the United States. The American Government, as a rule, does not care to sanction the landing of cables on American territory by an association which, from the exclusive rights it might have acquired, could oppose obstacles, in another country, to the landing of cables by any American citizen. It must be remembered that reciprocity is a leading feature in American politics. It is not probable, however, that the French company will, on account of this temporary difficulty, be long debarred from that outlet which is of so vital importance to its interests. Sooner or later it is certain to find means for obtaining the communication necessary to guarantee the efficiency of its system.

Although, as above set forth, the French Company is, for the time being, hampered in its action, a distinct gain to it in another direction fully compensates for that temporary inconvenience. The struggle for the possession of Brazilian and other South American traffic has assumed an acute phase, and energetic measures are being undertaken by rival enterprises on both sides of the South American continent to secure this traffic. The Western and Brazilian Company on the east coast is in strong competition with the Central and South American Company on the west coast; and when the French West India lines are completed to Brazil it is fair to assume that the Western and Brazilian Company will find it to their advantage to work in accord with the new enterprise. It is evident that the French cables offer a more natural route for telegraphic communications between North and South America than the existing one by which this traffic is under the necessity of twice crossing the Atlantic. That the importance of the commercial relations between South America and the United States fully justifies the establishment of the new communications, is shown from the estimated value of South American telegraph business, which may be placed at about £300,000 per annum. It is probable that of the messages represented by this amount a satisfactory proportion will be diverted to the French cables.

*The Submarine Cable Systems of the Compagnie Télégraphique des Antilles and the Société Française des Télégraphes Sousmarins.*

So far as the Brazilian traffic with the United States is concerned, the West India and Panama Company can hope for no share; but it is otherwise as regards the Cuba Submarine and the International Ocean Telegraph Companies. It is beyond question that these associations have everything to gain from friendly alliance with the new enterprise, since their systems would directly benefit by such traffic as might come to them from the French cables; and, further, these amicable relations might secure immunity from the consequences to be expected by the establishment of competing lines. Let these companies take warning from the isolation which the West India and Panama Company has brought upon itself.

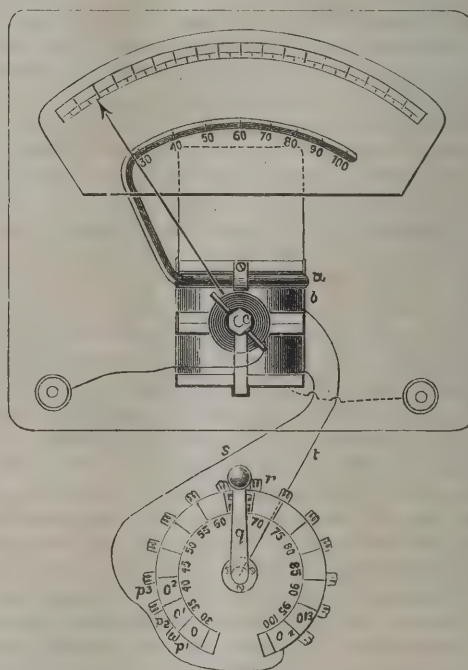

The accompanying table showing the cables of the French companies laid, in progress, and contemplated, may assist to an appreciation of the situation.

### WESTON'S TEMPERATURE REGULATOR FOR MEASURING INSTRUMENTS.

AMONG the errors to which electric measuring instruments are subject is that due to the heating of the coils by the passage of the current. This evidently increases their resistance, and changes the value of the readings indicated. To avoid this as much as possible recourse is had to wire having as low a temperature co-efficient as possible; but such wire of German silver or platinoid is very expensive when the finer sizes are employed, and hence it becomes desirable to retain copper wire if some means can be provided for correcting the error due to the change in resistance resulting from temperature variations.

Realising this disadvantage, says the *Electrical Engineer*, N.Y., Mr. Edward Weston, Newark, N.J., has recently brought out an important addition to his well-known and admirable instruments, consisting of a temperature regulator, but which is, of course, applicable to instruments wound with whatever kind of wire.

In order that variations in temperature may be recognised, Mr. Weston provides a thermometer, *m*, the mercury bulb of which is elongated, and is curved and fastened directly against the exterior of the coil. The thermometer tube is bent, as shown, and arranged upon the scale plate, and in a curve parallel to that of the scale markings. By means of this thermometer the temperature of the coil is shown upon the same scale plate as the regular indications of the instrument.

A series of contacts, *o* to *o*<sup>14</sup>, insulated from one another, are arranged in a circle, and between the successive contact plates are included resistance coils, *p*<sup>1</sup>, *p*<sup>2</sup>, *p*<sup>3</sup>, &c. Pivoted concentrically with the circle of contact plates is a switch-arm, *q*, having contact springs bearing upon the surface of the contact plates, *o*.

This device is interposed in the circuit of the fixed coil, and is connected to it by the wires, *s*, *t*. The contact plates, *o*, *o'*, &c., are marked to correspond to the thermometer scale. Thus the contact plate, *o*, is marked "30" to correspond to the 30° mark of the thermometer, the contact plate, *o'*, corresponds to the 35° mark of the thermometer, and so on, the contact plate, *o*<sup>14</sup>, corresponding to the 100° mark. When the arm, *q*, is placed on the contact plate, *o*, it will be evident that the current in the instrument then passes through all the resistances, *p*, *p*<sup>1</sup>, *p*<sup>2</sup>, and, *p*<sup>3</sup>.

Suppose, for instance, that this is the starting point of temperatures, and that the heat of the coil increases, so that the thermometer shows a temperature of 65°. This means an increase of resistance in the coil due to the 65° difference of temperature. In order to compensate for this the switch arm, *g*, is moved around until its contact spring rests on the plate, *o'*, marked "65." Seven resistances, *p*, *p'*, will thus be thrown out of the circuit, and as each resistance corresponds to the increase of resistance in the coil due to the elevation of 5° of temperature, it follows that by throwing out seven of these resistances we have exactly compensated for the increased resistance of the coil due to its increased heat.

In practical operation, therefore, it is simply necessary to note the indication of the thermometer, and place the arm, *g*, on the contact plate mark corresponding to that indication, in order to keep the resistance of the circuit in the instrument uniform.

## ELECTRIC RAILWAYS.\*

By THEO. P. BAILEY.

THE practical development of electric street railways, and their commercial perfection, may properly be said to have been accomplished within two years, and yet there are at the present time 246 electrical street railway plants either in operation, or ready to be put in operation, within a short time. Two years ago, and even within the past 12 months, we were asked many questions by intending purchasers, which to-day are not even hinted at. Some of the prevailing questions of that age were:—

Can electricity be applied in our case?

Can a street railway, equipped with electricity, be made a practical and commercial success?

What will be the life of the apparatus?

What will it cost to keep the apparatus in repair?

Is not the current dangerous to human life?

Will it not ruin the watches of passengers?

The street railway people to-day appear to have become thoroughly satisfied on these questions, and consider it an idle waste of time to discuss them further. But in lieu they ask us this: "How soon can you furnish the equipment for our road, and what will it cost?" Just think of this statement for a moment: Two hundred and forty-six electrical railways in operation, embracing 2,024 miles of track, and 3,830 motor cars, requiring in the neighbourhood of 6,400 motors with a probable aggregate capacity of 174,435 horse-power, employing an electrical generating capacity at the station of about 94,880 horse-power! Did any one of you anticipate two years ago that such a condition of facts could under any circumstances be realised within so short a time? I attribute this wonderful development and success to the following causes:—

First, the full practicability of the undertaking; second, the wonderful earning capacity of the electrically equipped car as compared with the horse car; third, a determination on the part of the electrical manufacturers to meet the requirements of the railway companies; and fourth, the untiring and undefatigable efforts of the exploiter or salesman.

Among the numerous and possibly fatal objections raised to the use of electricity, when it was proposed to apply it to street car propulsion, was that grades exceeding 5 per cent. could not be mounted. But experience and practice have shown that grades as high as 14 per cent. can be ascended with reasonable safety and satisfaction. There is a grade of 13  $\frac{1}{10}$  per cent. at one point on the line of the street railway at Lynn, Mass., over which 16-foot cars equipped with two 15 horse-power motors are in daily and successful operation. At Milwaukee a grade of 10  $\frac{3}{10}$  per cent., 430 feet long, is encountered and successfully operated over by 20-foot cars, equipped with two 15 horse-power motors, the total weight of car complete with passengers being 10  $\frac{1}{2}$  tons. A similar grade is met with at Newport, R.I., and Omaha, Neb., and numerous grades almost as heavy are seen in the electric railway systems at Des Moines and Davenport, Ia., and Kansas City, Mo.

At the present time there are as nearly as can be ascertained 957 street railways in the United States and Canada. Of this number 589 are operated by horses; 49 by cable; 246 by electricity; 73 by steam.

It is estimated that the total money value of these combined properties is \$164,400,000, proportioned as follows:—Horse railways, \$58,900,000; cable railways, \$49,000,000; electric railways, \$49,200,000; steam railways, \$7,300,000.

These figures are at best only approximations, as it has been found impossible to secure absolutely accurate information.

This combination of motive powers is doing service over or upon 8,818 miles of track as follows:—Horses, 5,713; cable, 527; electric, 2,024; steam, 554.

I find that the cost per car mile for the several methods referred to, including all operating expenses and fixed charges, other than interest, is as follows:—Horses, 5.7 cents; cable, 2  $\frac{1}{2}$  cents; electric, 2.2 cents; steam, 5 cents.

A large majority of the street cars equipped electrically at the present time are mounted upon a single truck, to which are attached one or two motors, as required by the conditions existing in each particular case. The lightest equipment with which I have had to do has been a single 15 horse-power motor upon one truck; and the heaviest equipment has been two 15 horse-power motors upon one truck. The tendency, however, at the present time seems to be in the direction of longer cars, double trucks, and heavier motors. This action is prompted very largely, no doubt, by the sad and costly experience of some companies where trailers were used in connection with the motor car; serious accidents, and in some cases death, having resulted from injuries sustained by passengers in falling between the motor and trail car while passing from one to the other.

The use of the longer car with double trucks is recommended further as a means of comfort to the passengers, and also on account of the longer life of the car and its equipments. This style of car is, of course, unattended by the oscillating motion found in the shorter car with a single truck. Where the shorter motor car is used with a trailer experience shows that there is a great loss in wear and tear by reason of the cars jamming together when the brakes are applied. This fault is obviated in the longer car, and while its seating capacity may not be equal to that of two shorter cars, it is approximately so. It is claimed further for the longer car with double trucks that less energy is required to operate it; also that it saves the expense of one man, decreases the expense of maintenance, and increases the facility for handling passengers.

In treating of the subject of electric railways from a commercial standpoint, I have considered only that branch designated as the single wire overhead system.

For obvious reasons too much care cannot be observed in planning and locating the various factors which go to make up a complete electric railway plant. Assuming that the railway company has secured the desired franchises and rights of way, has laid out its lines of track so as to avoid all excessive grades, and yet reach the attractive and important points of the town or city, and that it has been fortunate enough to make proper selection of its apparatus, the next important work for it to determine is the location and arrangement of its power station. The selection of a site should be made with reference to obtaining the best facility for handling coal and securing water, and also with reference to the electrical centre of the railway system, in order to realise the highest degree of economy in the operation of the plant. The arrangement of the power station is equally as important as its location, with regard to handling the work with the least cost for labour. The selection of the steam plant is a matter of great importance, and should be left with a thoroughly competent and reliable engineer to determine what particular type of engine, boiler, &c., should be used; and the matter should be left under his direction and care until the installation has been completed. It is manifest that in so doing serious blunders will be avoided. I do not think it can be justly claimed that the railway companies have been too liberal in the amount of horse-power purchased for the operation of their generators. In order to secure the best results, with reference to reliability of service, the horse-power of the engine should be at least 20 per cent. greater than that of the generator which it drives, in order to provide for loss in transmission and excessive loads which are thrown on the generator by reason of a large number of cars starting at the same time; or on account of a ground being accidentally thrown upon the line. The steam plant should be so arranged and connected to the generators that either engine or generator may be readily interchanged; and the arrangement of the engines and generators should be made with reference to future extensions. The switch-board containing the indicating and regulating devices, should be located so as to be most accessible to the attendant.

Both the power and electrical plant when complete and ready for operation, should be placed in the hands of men of experience and learning in these departments, in order to ensure reliability of service, and the greatest economy in operation and maintenance. I would rather provide in advance for the expenditure of \$1,000 or more in this department than to run any risk of having to pay out four times that amount in repairs and losses occasioned by mistakes of incompetent men.

The location and arrangement of the car house is a question of considerable importance, and open to serious mistakes growing out of bad location or improper interior arrangement. Some advantages are secured by locating the car house immediately adjacent to the power station. In this case it may be heated with the exhaust steam from the power plant, and the services of employees utilised in both buildings, and repairs to apparatus concentrated at one point. The car house should be provided with suitable pits for the inspection of the motors, and also have proper accommodations for cleaning the car bodies. If the car house is to accommodate more than 20 or 25 cars, it should be provided with running and turning tables, and should also have more than one exit.

I cannot pass from the question of inspection of apparatus without emphasising the extraordinary importance of having this work done thoroughly by competent and faithful attendants. With electrical apparatus of standard makes we can reasonably expect that a motor car sent out in the morning for the work of the day, having passed through proper inspection, will perform its duty with a degree of certainty that need leave but little, if any, cause

\* Read before the Chicago Electric Club, November 17th, 1890.

for anxiety. This feature is, perhaps, the most difficult one to impress upon the management of electrical railway companies, more especially where such railways have been converted from animal power. If railway companies will guarantee that degree of care and watchfulness in the operation of their motors indicated above, we take practically no chances by giving them the broadest guarantees as to the durability of the apparatus, and the cost of maintenance and repair.

It is apparent that in the overhead construction the highest degree of care should be exercised as to its details and arrangement, for this part of the equipment is constantly open to criticism. We cannot blind our eyes to the fact that serious, and, in some instances, fatal criticism has been made to this work. We must all avail ourselves of the experience which has attended our efforts, and see to it that our overhead construction is not in any case, or for any reason, slighted.

I think an iron pole 28 or 30 feet long, made in three sections of extra strong pipe 6 inches in diameter at the base, and 4 inches at the top, provided with wheel base and insulated cap, presents the most slightly appearance on the street, and forms the most substantial construction that can be had. Next in reliability and appearance is an octagonal pole of Southern pine suitably painted; and, lastly, and the pole most commonly used, the Western Union standard. These poles should be properly set with sufficient rake to allow of sustaining a strain of at least 900 lbs. To these poles should be attached by means of eye-bolts a galvanised steel wire having a diameter of at least  $\frac{1}{4}$  of an inch, and drawn taut so that the poles will come to a perpendicular position. To these span wires there should be attached a suitable insulating device over the centre of each track with proper attachments for suspending the trolley wire. This insulating device should be small in its construction, consistent with strength and high insulation, and the insulating material formed in such manner that it will in itself constitute a protection against moisture. The trolley wire should, in my judgment, be at least  $\frac{3}{8}$ ths of an inch in diameter, considering the objection that is raised to the multiplication of wires in the streets. This wire should be hard-drawn copper in lengths of at least one mile each. In this case, the number of splices is reduced to a minimum, and by means of a suitable splicing ear the joints can be neatly, perfectly, and securely made.

Where the streets are of a width of at least 60 feet from curb to curb, it is regarded as thoroughly safe and practicable in cases of double track roads to place the poles in the centre of the street between the tracks, and whether these poles be made of iron or of wood of octagonal shape, I consider that this arrangement presents the best form of overhead construction that can be secured.

When a conduit can be constructed that will permit of the safe, reliable and economical operation of street railways by means of electricity, we will all rejoice, and be glad. If its first cost can be made sufficiently reasonable to permit its use in cities of, say 50,000 inhabitants, it will be a magnificent achievement, and one that will surely bring its just reward to the successful inventor.

This thought is not prompted by reason of any vexatious troubles or annoyances which have occurred in the operation of the overhead system, but wholly on account of the objections which have been raised to the rapid multiplication of poles and wires in the streets, occasioned by the remarkable development and progress of the electrical science.

One of the prominent electrical companies is, and has been for some time, carrying on extensive and elaborate experiments with conduits, but have not, I believe, fully satisfied themselves of the commercial success of their latest undertaking.

I find little or no objection to overhead wires in place of less than 50,000 inhabitants. For this reason, and the fact of its low first cost, the overhead system will no doubt continue to be used in such places for some time to come, regardless of developments in the conduit system.

One of the most important features of an electric railway system is the track or road bed. My experience has been that sufficient attention has not been given to that part of the equipment, especially until very recently. The track should be constructed of a good form of girder or "T" rail, weighing 54 lbs. or 40 lbs. per yard respectively, and should be attached securely to suitable ties placed not more than  $2\frac{1}{2}$  feet apart. It should be well ballasted, and where crossings are made over other tracks solid castings should be used in order to prevent the jolting and jarring which occurs when passing over them. The rails should be kept as clean as possible where they are used as a part of the return circuit. In order to use the rails of the track in completing the return circuit they should be firmly connected together by a copper wire in addition to the ordinary fish plates, and in certain cases, depending wholly upon the length of the line, number and extent of grades, and number of cars and amount of traffic, there should be used a supplementary copper wire, the size of which must depend upon the conditions just named. It is asserted by some electricians that the efficiency of the return circuit is increased in all cases by the use of a supplementary wire; but my experience has been upon small roads where the grades and traffic are light, that satisfactory and economical operation is secured where the supplementary wire is omitted.

Some of the essential requisites of an electric motor car are proper controlling mechanism and reversing switch for controlling the speed and direction of the car, a lightning arrester and multiple fuse box. It should also be provided with suitable life guards, bells, and head lights. The wheels of the car should in my judgment be at least 33 inches in diameter and weigh 300 lbs. each.

This will give increased adhesion and allow the motors to be raised sufficiently high from the ground to prevent practically the possibility of its being injured by striking obstacles between the rails.

Increased speed with a very slight increase of power will result by the use of the 33-inch instead of the 30-inch wheel.

The possible speed of a car equipped electrically is measured only by the limit of safety. The regulation speed in the majority of places is twelve miles per hour, and the average mileage per car per day about 115. It is well known that upon well regulated steam railroads the locomotives rarely make a continuous run of over 100 miles per day; and considering the extraordinary care that is given to them, and remembering in the same connection the very slight degree of care given to the average electric street railway motor, I think the latter is entitled to a very handsome compliment for the good service it gives us; and when you know that the best average mileage that can be made by a car propelled by the Kentucky horse or Texas mule is 60 miles per day, and even in doing this it is necessary to make at least four changes per day, I think you will admit that the electric railway motor is doing most admirable service.

The smallest town in the United States which has an electric street railway in operation is Southington, Conn., with a population of 5,400. Two cars are in service over two miles of track, and the average daily receipts are \$9.00 per car. The power for the operation of this road is furnished by the local lighting company, and costs \$1.25 per car per day. The largest electric railway is at Boston, Mass. The entire system comprises 284 miles of track, sixty of which are electrically equipped, and there are 312 motor cars in operation. During the month of August they had 300 motor cars in service, making a total mileage of 384,700,000. The mileage of the tow cars 59,948,000; making a total car mileage of 444,648,000. From August 10th to August 16th, 700,000 passengers were carried by these cars without a single delay. In the month of September, 312 motor cars were in operation, making a mileage of 343,466,000, and the mileage of tow cars 56,047,000, making a total car mileage of 399,513,000. The following is a statement of one road:—

Average number of motor cars run per day...	20
Average number of trail cars run per day ...	0
Average number of hours per car in service per day ...	18
Average number of miles per car per day ...	108
Electromotive force ...	500
Average ampère readings taken hourly ...	122
Average electrical horse-power ...	81.8
Average electrical horse-power per car ...	4.9
Number of passengers carried per day ...	11,060
Number of passengers carried per car per day ...	553
Cost of operating per car mile ...	\$ 0616
Receipts per car mile ...	2560
Cost of operating per car per day ...	6 65
Receipts per car per day ...	27.65

Most flattering testimonials have been received from railway companies who have adopted the electric system, and while they express their absolute satisfaction with the new motive power they also state, that the earning capacity of their road has been materially increased. In some cases the increase is given as high as 400 per cent., and in others as low as 50 per cent., but in no case that I can now remember has the increase been given lower than the amount last stated.

Inquiry is sometimes made as to whether a motor car can be safely and reliably operated without a conductor. The present form of trolley and overhead construction readily permits of this; but I do not regard it as practicable or advisable except in the smaller places where the business of the road will not justify the expense of a conductor. I am familiar, however, with a number of roads in towns or cities having a population of less than 30,000 where the car is in the exclusive charge of the motorman, and no trouble is experienced in its operation. With a good track there is little, if any, possibility of accident when proper care is exercised in taking curves and switches. Where the business will warrant the expense, however, there should be a conductor with every car or train.

We cannot overlook the fact that there are still some complaints of excessive cost for repairs and maintenance of the electrical apparatus, but I insist that the responsibility for this condition does not rest altogether with its manufacturers. The managers of these electric roads must appreciate that they are exacting a greater mileage duty of their motors than is expected of the ordinary railroad steam engine and under conditions manifestly more unfavourable. If they will admit this, and see to it that their tracks are put in good order and so maintained, and the same degree of care and attention given to their motors that is given to the steam engine, I am satisfied they will have little to complain of. How rarely do you find an electric motor operated on a track like that prepared for the steam engine? And how seldom do you find a man in charge of the motor car who has the intelligence, training and experience of the steam engineer?

Several railway companies which adopted the cable system before the possibilities of the electric system were fully appreciated or understood, are now seriously considering the complete displacement of that system and the substitution of electricity in its stead. I was recently informed by the president of one of the electric railway companies, whose line is a competitor to a cable road, that the latter company, feeling keenly the effect of the

competition of the electric system had about concluded to reduce the fare on their road to 4 cents per passenger. Before this action takes place, however, I have no doubt that some bright representative of the electric system will persuade our cable friend to join the procession of progress, abandon the cable, welcome and adopt electricity as the motive power, and thus preserve the independence and stability of his street railway system.

There is no system or method of rapid street transportation that is so universally popular as the electric system; its wonderful flexibility is unparalleled in the history of street railways; capable of moving in either direction with equal facility, its value is materially enhanced from the standpoint of safety. Its first cost is about the same as for the animal system, and considerably less than the cable system. Knowing what the possibilities of the electric system are, and how cheaply it can be maintained and operated under proper conditions, I think we will see street railways thus equipped in many towns of a population not exceeding 10,000, and in some cases even less, and at a period not very remote.

I have previously alluded to the remarkable growth of the electric railway business, and given some reasons for it, but I do not feel that full justice has been done to the pioneers—I mean the manufacturers of the apparatus. When you consider what they had to do, and what they did do, in order to inspire confidence in the undertaking, I think you will all agree with me that they have merited even greater success than has attended their efforts, if that be possible. Contracts with all sorts of guarantees were made, long trial periods were given, the cost of maintenance guaranteed to be less than for the same number of cars operated by animal power, the current guaranteed not to be fatal to human life, and the system warranted to work in a thoroughly practical and successful manner, with a general and sweeping provision that in case of failure in any of the guarantees, the railway company could, at their option, throw the apparatus out, and assess the electrical company any damages which they had sustained by reason of the alleged experiment. Was there ever a new industry vouched for so absolutely by its projectors? Had the electric companies been less liberal with their guarantees, and not exhibited such a marked degree of confidence themselves, we undoubtedly would have been able to-day to count the number of electric railways by tens instead of by hundreds, for it is but a short time since the financial world has given its unqualified indorsement to the system. Bankers and trust companies took no part in formulating public sentiment or confidence in this matter. The undivided burden was assumed and borne by the electrical company, and not until they had fulfilled their numerous guarantees faithfully and well, and demonstrated beyond all peradventure the full and complete success of the electric street railway was the moneyed man or corporation willing to assume any hazard or risk. How the conditions have changed in two short years! Every principal city in the United States now has its electric street railway; full confidence has been established, and unreasonable guarantees are no longer required.

In closing, permit me to offer this prediction, that within a few years, surface and elevated railways operated by animal, cable, or steam power, will be numbered with the events of the past, and electricity, with all its beautiful attributes, in all its grandeur and magnificence, and in the full measure of the wide range of its possibility, will claim supremacy in the broad realm of street railway transportation.

## THE ELECTRO-MAGNET.\*

By Prof. SILVANUS P. THOMPSON, D.Sc., B.A., M.I.E.E.

(Continued from page 747.)

### EFFECT OF USING CONED PLUNGERS.

But now if, instead of employing a cylindrical core, you employ one that is pointed, you find this completely alters the position of the maximum pull, for now the point is insufficient to carry the whole of the magnetic lines which are formed in the iron rod. They do not come out at the point, but filter through, so to speak, along the sides of the core. The region where the magnetic lines come up through the iron into the air is no longer a definite "pole" at or near the end of the rod, but is distributed over a considerable surface; consequently when the point begins to poke its nose out, you still have a larger portion of iron up the tube, and the pull, instead of coming to a maximum at that position, is distributed over a wider range. I am now making the experiment roughly with my spring balance and a conical plunger, and I think you will be able to notice a marked difference between this case and that of the cylindrical plunger. The pull increases as the plunger enters, but the maximum is not so well defined with a pointed core as it is with one that is flat-ended. This essential difference between coned plungers and cylindrical ones was discovered by an engineer of the name of Krizik, who applied his discovery in the mechanism of the Pilsen arc lamps. Coned plungers were also examined by Bruger. In fig. 63 are given the

curves that correspond to the use of a coned iron core, as well as those corresponding to the use of the cylindrical iron rod. You will notice that, as compared with the cylindrical plunger, the coned core never gave so big a pull, and the maximum occurred not as the tip emerged, but when it got a very considerable way out on the other side. So it is with both the shorter and the longer coil. The dotted curves in fig. 64 represent the behaviour of a coned plunger. With the longer coil represented, and with various currents, the maximum pull occurred when the tip had come a considerable way out; and the position of the maximum pull, instead of being brought nearer to the entering end, with a high magnetising current, was actually caused to occur further down; the range of action became extended with large currents as compared with small ones. Bruger also investigated the case of cores of very irregular shapes, resembling, for example, the shank of a screw-driver, and found a very curious and irregular force-curve. There is a good deal more yet to be done, I fancy, in examining this question of distributing the pull on an attracted core by altering the shape of it; but Bruger has shown us the way, and we ought not to find very much difficulty in following him.

### OTHER MODES OF EXTENDING RANGE OF ACTION.

Another way of altering the distribution of the pull is to alter the distribution of the wire on the coil. Instead of having a coned core use a coned coil, the winding being heaped up thicker at one end than at the other. Such a coil, wound in steps of increasing thickness, has been used for some years by Gaiiffe, in his arc lamp; it has also been patented in Germany by Leupold. M. Trève has made the suggestion to employ an iron wire coil, so to utilise the magnetism of the iron that is carrying the current. Trève declares that such coils possess, for an equal current, four times the pulling power. I doubt whether that is so; but even if it were, we must remember that to drive any given current through an iron wire, instead of a copper wire of the same bulk, implies that we must force the current through six times the resistance; and, therefore, we shall have to employ six times the horse-power to drive the same current through the iron wire coil, so that there is really no gain. Again, a suggestion has been made to enclose in an iron jacket the coil employed in this way. Iron-clad solenoids have been employed from time to time. But they do not increase the range of action. What they do is to tend to prevent the falling off of the internal pull at the region within the mouth of the coil. It equalises the internal pull at the expense of all external action. An iron-clad solenoid has practically no attraction at all on anything outside of it, not even on an iron core placed at a distance of half a diameter of the aperture; it is only when the core is inside the tube that the attraction begins; and the magnetising power is practically uniform from end to end. Last year I wished to make use of this property for some experiments on the action of magnetism on light, and for that purpose I had built, by Messrs. Paterson and Cooper, this powerful coil, which is provided with a tubular iron jacket outside, and a thick iron disc perforated by a central hole covering each end. The magnetic circuit around the exterior of the coil is practically completed with soft iron. With this coil, one may take it, there is an absolutely uniform magnetic field from one end of the tube to the other; not falling off at the ends, as it would do if the magnetic circuit had simply an air return. The whole of the ampère-turns of exciting power are employed in magnetising the central space, in which, therefore, the actions are very powerful and uniform. The coil and its uses were described in my lecture last year at the Royal Institution on "Optical Torque."

### MODIFICATIONS OF THE COIL AND PLUNGER.

In one variety of the coil and plunger mechanism, a second coil is wound on the plunger. Hjörth used this modification, and the same thing has been employed in several arc lamps. There is a series of drawings upon this wall, depicting the mechanism of about a dozen different forms of arc lamp, all made by Messrs. Paterson and Cooper. In one of these there is a plunger, with a coil on it, drawn into a tubular coil, the current flowing successively through both coils. In another there are two separate coils in separate circuits, one of thin wire and one of thick, one being connected in series with the arc, and one in shunt.

### DIFFERENTIAL COIL AND PLUNGER.

There is a third drawing here showing the arrangement, which was originally introduced by Siemens, wherein a plunger is drawn at one end into the coil that is in the main circuit, and at the other end into a coil that is in shunt. That differential arrangement has certain peculiar properties of which I must not now stop to speak in detail. It is obvious that where one core plunges its opposite ends into two coils, the magnetisation will depend on both coils, and the resultant pull will not be simply the difference between the pull of the two coils acting each separately. There is, however, another differential arrangement, used in the Brockie-Pell and other arc lamps, in which there are two separate plungers attached to the two ends of a see-saw lever. In this case the two magnetising actions are separate. In a third differential arrangement there is but one plunger and one tubular bobbin, upon which are wound the two coils, differentially, so that the action on the plunger is simply due to the difference between the ampère-turns circulating in the two separate wires.

\* Cantor Lecture. Delivered before the Society of Arts, February 3rd, 1890.

## COIL AND PLUNGER COIL.

When one abandons iron altogether, and merely uses two tubular coils, one of wide diameter, and another of narrower diameter, capable of entering into the former, and passes electric currents through both of them, if the currents are circulating in the same fashion through both of them they will be drawing into one another. This arrangement has also been used in arc lamps. The parallel currents attract one another inversely, not as the square of the distance, but approximately as the distance. This is one of those little details about which it is as well to be clear. About once a year some kind friend from a distance writes to me pointing out a little slip that he says occurs in my book on electricity, in the passage where I am speaking about the attraction of parallel wires. I have made the terrible blunder of leaving out the word square; for I say the attraction varies inversely as the distance, and my readers are kind enough to correct me. Now when I wrote that passage I considered carefully what I had to write, and the attraction does not vary inversely as the square of the distance, because two parallel wires do not act on one another as two points. They act as two straight lines or two parallel lines, and the attraction between two parallel lines of current, or two parallel lines of magnetism, or two parallel lines of anything else that can attract, will not act inversely as the square, but simply inversely as the distance is between.

## INTERMEDIATE FORMS.

Now this property of the coil and plunger of extending the range of action has been adopted in various ways by inventors whose object was to try and make electro-magnets with a sort of intermediate range. For certain purposes it is desirable to construct an electro-magnet which, while having the powerful pull of the electro-magnet, should have over its limited range of action a more equable pull, resembling in this respect the equalising of range of the coil and plunger. Some of these intermediate forms of apparatus are shown in the following diagrams. Here (fig. 65)

FIG. 65.—PLUNGER ELECTRO-MAGNET OF STEVENS AND HARDY.

is a peculiar form of electro-magnet; it combines some of the features of the iron-clad electro-magnet with those of the movable plunger; it has a limited range of action, but is of great power over that range, owing to its excellent magnetic circuit. It was invented in 1870, by Stevens and Hardy, for use in an electric motor for running sewing machines. A very similar form is used in Weston's arc lamp. A form of plunger electro-magnet, invented by Holroyd Smith in 1877, resembles fig. 65 inverted, the coil being surrounded by an iron jacket, whilst a plunger, furnished at the top with an iron disc, descends down the central tube to meet the iron at the bottom.

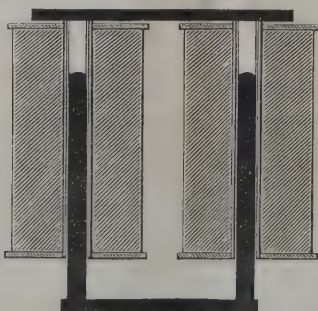

FIG. 66.—ELECTRO-MAGNET OF BRUSH ARC LAMP.

Then there is another variety, of which I was able to show an example last week by the kindness of the Brush Company, namely, the plunger electro-magnet employed in the Brush arc lamps. A couple of tubular coils receive each an iron plunger, connected

together by a yoke; whilst above, the magnetic circuit is partially completed by the sheet of iron which forms part of the enclosing box. You have here, also, the advantage of a fairly complete magnetic circuit, together with a comparatively long travel of the plunger and coil. It is a fair compromise between the two ways of working. The pull is not, however, in any of these forms, equal all along the whole range of travel; it increases as the magnetic circuit becomes more complete.

There are several other intermediate forms. For example, one inventor, Gaiser, employs a horseshoe electro-magnet, the cores of which protrude a good distance beyond the coils, and for an armature he employs a piece of sheet iron, bent round so as to make at its ends two tubes, which enclose the poles, and are drawn down over them. Contrast with this design one of much earlier date by an engineer, Roloff, who made his electro-magnets with iron cores not standing out, but sunk below the level of the ends of the coils, whilst the armature was furnished with little extensions that passed down into these projecting tubular ends of the coils. Some arc lamps have magnets of precisely that form, with a short plunger entering a tubular coil, and met half-way down by a short fixed core inside the tube.

Here (fig. 67) is one form of tubular ironclad electro-magnet that deserves a little more attention, being the one used by Messrs. Ayrton and Perry in 1882; a coil has an iron jacket round it, and also an annular iron disc across the top, and an annular iron disc across the bottom, there being also a short internal tube of iron extending a little way down from the top, almost meeting another

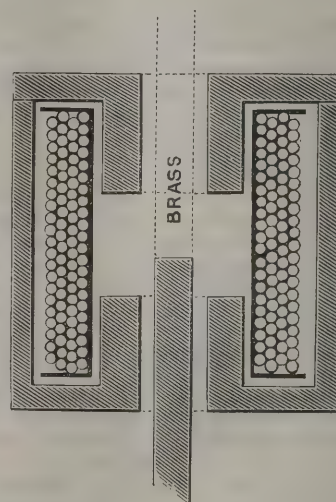

FIG. 67.

AYRTON AND PERRY'S TUBULAR IRONCLAD ELECTRO-MAGNET.

short internal tube of iron coming up from the bottom. The magnetic effect of the enclosed copper coil is concentrated within an extremely short space, between the ends of the internal tubes, where there is a wonderfully strong uniform field. The range of action you can alter just as you please in the construction by shortening or lengthening the internal tubes. An iron rod inserted below is drawn with great power and equality of pull over the range from one end to the other of these internal tubes.

## ACTION OF MAGNETIC FIELD ON SMALL IRON SPHERE.

In dealing with the action of tubular coils upon iron cores, I showed how, when a very short core is placed in a uniform magnetic field, it is not drawn in either direction. The most extreme case is where a small sphere of soft iron is employed. Such a sphere, if placed in even the most powerful magnetic field, does not tend to move in any direction if the field is truly uniform. If the field is not uniform, then the iron sphere always tends to move from the place where the field is weak to a place where the field is stronger. A ball of bismuth, or one of copper, tends, on the contrary, to move from a place where the field is strong to a place where the field is weaker. This is the explanation of the actions called "dia-magnetic," which were at one time erroneously attributed to a supposed diamagnetic polarity opposite in kind to the ordinary magnetic polarity. A simple way of stating the facts is to say that a small sphere of iron tends to move up the slope of a magnetic field, with a force proportional to that slope; whilst (in air) a sphere of bismuth or one of copper tends, with a feeble force, to move down that slope. Any small piece of soft iron—a short cylinder, for example—shows the same kind of behaviour as a small sphere. In some of Ayrton and Perry's coiled-ribbon ampère-meters and voltmeters, and in some of Sir William Thomson's current meters, this principle is applied.

## SECTIONED COILS, WITH PLUNGER.

An important suggestion was made by Page, about 1850, when he designed a form of coil and plunger having a travel of indefinitely long range. The coiled tube, instead of consisting merely of one coil, excited simultaneously throughout its whole length by the current, was constructed in a number of separate sections or short tubes, associated together end to end, and furnished with means for turning on the electric current into any

of the sections separately. Suppose an iron core to be just entering into any section, the current is turned on in that section, and as the end of the core passes through it, the current is then turned on in the section next ahead. In this way an attraction may be kept up along a tube of indefinite length. Page constructed an electric motor on this plan, which was later revived by Du Moncel, and again by Marcel Deprez in his electric "hammer."

#### WINDING OF TUBULAR COILS AND ELECTRO-MAGNETS.

The mention of this mode of winding in sections leads me to say a few final words about winding in general. All ordinary coils, whether tubular or provided with fixed cores, are wound in layers of alternate right-handed and left-handed spirals. In a preceding lecture I mentioned the mistaken notion, now disproved, that there is any gain in making all the spirals right-handed or all left-handed. For one particular case there is an advantage in winding a coil in sections; that is to say, in placing partitions or *cloisons* at intervals along the bobbin, and winding the wire so as to fill up each of the successive spaces between the partitions before passing on from one space to the next. The case in which this construction is advantageous is the unusual case of coils that are to be used with currents supplied at very high potentials. For when currents are supplied at very high potentials there is a very great tension\* exerted on the insulating material, tending to pierce it with a spark. By winding a coil in *cloisons*, however, there is never so great a difference of potentials between the windings on two adjacent layers as there would be if the layers were wound from end to end of the whole length of coil. Consequently, there is never so great a tension on the insulating material between the layers, and a coil so wound is less likely to be injured by the occurrence of a spark.

Another variety of winding has been suggested, namely, to employ in the coils a wire of graduated thickness. It has been shown by Sir William Thomson to be advantageous in the construction of the coils of galvanometers to use for the inner coils of small diameter a thin wire; then, as the diameter of the windings increase, a thicker wire; the thickest wire being used on the outermost layers; the gauge being thus proportioned to the diameter of the windings. But it by no means follows that the plan of using *graded wire*, which is satisfactory for galvanometer coils, is necessarily good for electro-magnets. In designing electro-magnets it is necessary to consider the means of getting rid of heat; and it is obvious that the outer layers are those which are in the most favourable position for getting rid of this heat. Experience shows that the under layers of coils of electro-magnets always attain a higher temperature than those at the surface. If, therefore, the inner layers were to be wound with finer wire, offering higher resistance, and generating more heat than the outer layers, this tendency to over-heating would be still more accentuated. Indeed, it would seem wise rather to reverse the galvanometer plan, and wind electro-magnets with wires that are stouter on the inner layers and finer on the outer layers.

Yet another mode of winding is to employ several wires united in parallel, a separate wire being used for each layer, their anterior extremities being all soldered together at one end of the coil, and their posterior extremities being all soldered together at the other. Magnetically, this mode of winding presents not the slightest advantage over winding with a single stout wire of equivalent section. But it has lately been discovered that this mode of winding with *multiple wire* possesses one incidental advantage, namely, that its use diminishes the tendency to sparking which occurs at break of circuit.

#### EXTENSION OF RANGE BY OBLIQUE APPROACH.

I now pass to the means which have been suggested for extending the range of motion, or of modifying its amount at different parts of the range, so as to equalise the very unequable pull. There are several such devices, some electrical, others purely mechanical, others electro-mechanical. First, there is an electrical method. André proposed that as soon as the armature begun to move nearer, and comes to the place where it is attracted more strongly, it is automatically to make a contact, which will shunt off part of the current and make the magnetism less powerful. Burnett proposed another means; a number of separate electro-magnets acting on one armature, but as the latter approached these electro-magnets were one after the other cut out of the circuit. I need not say the advantages of that method are very hypothetical. Then there is another method which has been used many times with very great success, the method of allowing the motion of the armature to occur obliquely, it being mechanically constrained so as to move past, instead of towards the pole. When the armature is pulled thus obliquely, the pull will be distributed over a definite wider range. Here is a little motor made on that very plan. A number of pieces of iron set on the periphery of a wheel are successively attracted up sideways. An automatic device breaks the circuit as every piece of iron comes near, just at the moment when it gets over the poles, and the current being cut off, it flies on beyond and another piece comes up, is also attracted in the same way, and then allowed to pass. A large number of toy

motors have been made from time to time on this plan. I believe Wheatstone was the first to devise the method of oblique approach about the year 1841. He made many little electro-magnetic motors, the armatures of which were in some cases solid rims of iron arranged as a sort of wheel, with two or more zig-zag internal teeth, offering oblique surfaces to the attraction of an electro-magnet. Such little motors are often now used for spinning Geissler's vacuum tubes. In these motors the iron rim is fixed, and the electro-magnet rotates. The pole of the electro-magnet finds itself a certain distance away from the iron ring, it tries to get nearer. The only way it can get nearer is by swinging round, and so it gradually approaches, and as it approaches the place where it is nearest to the internal projection of the rim the current is cut off, and it swings further. This mode may be likened to a cam in a mechanical movement. It is, in fact, nothing else than an *electro-magnetic cam*. There are other devices, too, which are more like *electro-magnetic linkages*. If you curve the poles or shape them out you may obtain actions which are like that of a wedge on an inclined plane. There is an electro-magnet in one of

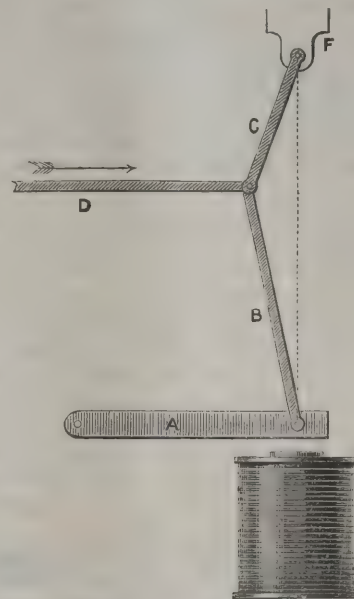

FIG. 68.—FROMENT'S EQUALISER WITH STANHOPE LEVER.

Paterson and Cooper's arc lamps wherein the pole-piece, coming out below the magnet, has a very peculiar shape, and the armature is so pivoted with respect to the magnet, that as the armature approaches the core as a whole, its surface recedes from that of the pole-piece, the effect being that the pull is equalised over a considerable range of motion. There is a somewhat similar device in De Puydt's pattern of arc lamp.

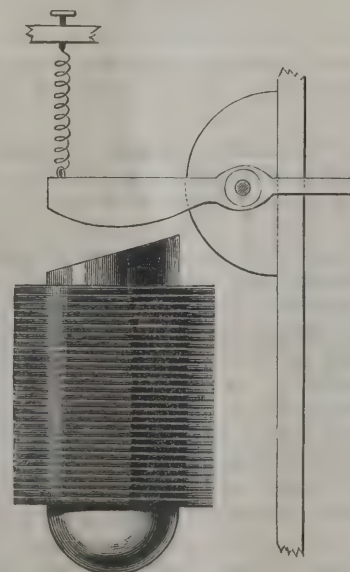

FIG. 69.

DAVY'S MODE OF CONTROLLING ARMATURE BY SPRING.

Here is another device for oblique approach, made by Froment. In the gap in the circuit of the magnet a sort of iron wedge is put in, which is not attracted squarely to either face, but comes in laterally between guides. Another of Froment's equalisers, or distributors, consists of a parallel motion attachment for the armature, so that oblique approach may take place, without actual

\* The tension on the insulating material, tending to pierce it with a spark, is proportional to the square of the difference of potentials (per unit thickness) to which the insulating material is subject. It is incorrect to talk about the tension of the conductor, or about the tension of the current; for the tension or electric stress is always an action affecting the di-electric or insulating material.

contact. Here, fig. 68, is another mechanical method of equalising devised by Froment, and used by Le Roux. You know the Stanhope lever, the object of which is to transform a weak force along a considerable range into a powerful force of short range. Here we use it backwards. The armature itself, which is attracted with a powerful force of short range, is attached to the lower end of the Stanhope lever, and the arm attached to the knee of the lever will deliver a distributed force over quite a different range. One way, not of equalising the actual motion over the range, but of counterbalancing the variable attractive force, is to employ a spring instead of gravity to control the armature. So far back as 1838, Edward Davy, in one of his telegraphic patents, described the use of a spring (fig. 69,) to hold back the armature. Davy preceded Morse in the use of a spring to pull back the armature. There is a way of making a spring act against an armature more stiffly as the pull gets greater. In this method there is a spring with various set screws set up against it, and which come into action at different ranges, so as to alter the stiffness of the spring, making it virtually stiffer as the armature approaches the poles. Yet another method is to employ, as the famous conjuror, Robert Houdin, did, a rocking lever. Fig. 70 depicts one of Robert Houdin's equalisers. The pull of the electro-magnet on the armature acts on a curved lever, which works against a second one; the point of application of force between the one and the other altering with their position. When the armature is far away from the pole, the leverage of the first lever on the second lever is great. When the armature gets near, the leverage of the first lever on the second is comparatively small. This employment of

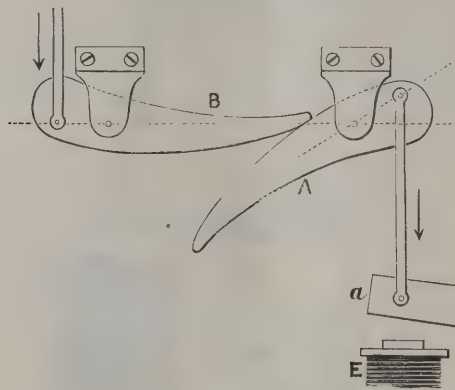

FIG. 70.—ROBERT HOUDIN'S EQUALISER.

the rocking lever was adopted from Houdin by Duboscq, and put into the Duboscq arc lamp, where the regulating mechanism at the bottom of the lamp contains a rocking lever.

(To be continued.)

## REVIEW.

*A Treatise on Electro-Metallurgy.* By WALTER G. McMILLAN, F.I.C., F.C.S. Charles Griffin & Co., London.

The aim of the author of this excellent treatise has been to explain the principles of his subject while avoiding "the accumulation of a mass of unnecessary detail." The work is divided into 18 chapters with addenda consisting of various useful tables.

In the first chapter, the scope of the subject is set down as including electrotyping, electroplating, extraction of metals from their ores, and the dissolving of the surfaces of metals. This is followed by an interesting historical sketch of the few isolated facts known to the ancients, and in the middle ages, up to the date of the discovery of the voltaic battery, which, together with the researches of Faraday and others, is then shown to have led to the remarkable development of the art in the present century. As is the case with so many other important inventions, electrotyping appears to have been simultaneously discovered by several different investigators; Jacobi, of St. Petersburg, and Spencer and Jordan in England.

The second chapter contains the physical and chemical knowledge necessary for understanding the subsequent chapters of the treatise, and though on the whole clear and to the point, we regret to say we have found more blemishes here than in any other part of the work. The author defines matter as that which

possesses *weight*; purely *mass* is the essential property of matter; weight is merely a force acting on matter, analogous to electric or magnetic attraction. Also no clear distinction is drawn between force and energy, of which latter, force forms only one factor; at page 22, "chemical force is converted into and rendered evident as heat energy;" and "it is no more possible to create force or energy, &c." A little further down on the same page we read: "We are rarely able to convert the whole of one kind of energy into any other;" the author should have said—*never*. The definition of a watt at p. 37 requires elucidation and amendment. "A current of 1 ampère at the pressure of 1 volt is termed a watt; it is a most useful unit for comparing different currents, and is really the product of volume into pressure;" the product of volume into pressure does not involve the element of time, whereas the *watt* does.

In Chapter III. we have excellent descriptions of batteries, dynamos, and other generators, suitable for electroplating; in some cases a little more detail, we think, might have been given. The author then proceeds to the more technical part of his subject, and here the subject matter is well chosen, and admirably arranged to suit the requirements either of a novice or of a practical electro-metallurgist. Chapter IV. contains general conditions to be observed in electroplating. Chapter V. relates to plating adjuncts and disposition of plant; and Chapter VI. to the cleansing and preparation of work for the depositing vat, and subsequent polishing of plated goods. In Chapter IV. we note a valuable table, showing the average current values suitable for depositing certain metals.

Chapters VII. to XIV. treat of the deposition of various metals and alloys. In each case valuable tables are given of the composition of the baths, giving also the authorities for their use, their special application, and other useful information. At p. 141, an interesting account is given of the experiments of Von Hübl on the effect of varying current strengths on the nature of the copper deposit; and at p. 147, the effect of the burnishing employed in the Elmore process on the tensile strength of the copper. The remaining chapters are devoted to metal extracting and refining processes, electrolytic quantitative analysis, and some other useful matters.

With the exception of the few blemishes which we have noticed above, and which may well be remedied in a second edition, we can commend Mr. McMillan's treatise as one of the best and most complete manuals hitherto published on electro-metallurgy.

## NOTES.

**Swansea and the Electric Light.**—At the last meeting of the electric lighting committee of the Swansea Corporation several reports were presented, amongst them being one from the borough surveyor, and another from Mr. W. H. Preece. The latter gentleman stated that the tender which complied with existing conditions was that of Messrs. Crompton and Company. The system was free from danger, and provided a continuous supply of electric energy of great constancy and steadiness. Speaking of street lighting, he stated that arc lamps, when placed not too far apart, and when they burned with steadiness, invariably gave satisfaction. Glow lamps, unless of considerable power, rarely did so. For street lighting, anything less than 32 C.P. was objectionable, and 50 C.P. was far preferable. The committee decided to accept the tender of Messrs. Crompton to erect twenty-three arc lamps of 2,000 C.P., at a cost of £25 each per annum, the increased charge for which over gas would be £171 per annum.

**Electricity and the Census.**—Austria is about to follow the example of America, and will use an electrical counter at the next taking of the census.

**Electric Lighting of Brussels.**—A Belgian daily newspaper states that the municipality of Brussels has definitely resolved not to grant a concession to any company for the electric lighting of that town, but to reserve to itself the right of exploiting the lighting. Thus the propositions which have been made to the municipality on the subject will not be carried into effect. This decision is said to have been arrived at owing to the conditions under which the town could buy up the station, &c., at the termination of the 25 years' concession, being too onerous.

**Lighting of Vienna.**—The Second Section of the Vienna Municipality has approved of the project between the latter and the International Compressed Air and Electricity Company. According to the scheme, the latter company is empowered to break up the streets to lay down cables and air-pipes, and the concession is given for 45 years. The Municipality can, however, on giving three years' notice, purchase the undertaking at the end of 15, 25, or 35 years.

**Electric Lighting at Bournemouth.**—At a meeting of the Bournemouth Town Council, last week, a letter was read from the Board of Trade forwarding the report and balance sheet of the Brush Electrical Engineering Company, who are carrying out an extensive installation in the favourite Hampshire watering place. The Town Clerk was instructed to reply that the accounts furnished appeared to show that the company was in a position to discharge the duties imposed by the order. Permission was also given the company to erect certain temporary overhead wires.

**The Brighton Council and the Brighton and Hove Electric Lighting Company.**—At a meeting of the Brighton Council last week, the General Purposes Committee reported the receipt of notice from the above company of an intended application to the Board of Trade for a Provisional Order, pursuant to the Electric Lighting Acts 1882 and 1888, and that they had instructed the Town Clerk to oppose on behalf of the Corporation, and authorised him to retain Parliamentary agents, counsel, and witnesses for that purpose.

**Electric Light in Post Office Work.**—It is said that the authorities contemplate installing the electric light in the Bristol general post office. The sorters and other officials, who are obliged to work long hours, complain of the considerable discomfort caused by the heat of the numerous gas jets in the various departments.

**Electric Light in Scarborough.**—The local authority has decided to apply for a provisional order.

**Progress of Civilisation.**—The King of the Sandwich Islands, who is at present in New York, is endeavouring to get a telegraphic cable laid between San Francisco and Honolulu.

**The Electric Light and Ventilation.**—The *Journal of Gas Lighting*, in a lengthy article on "Gas and Electric Lighting and Ventilation," thus concludes:—"There is no need for talking vaguely on this subject; and, in order to bring the question to an issue, we will take a familiar example—the hall of the Society of Arts. This hall is supposed to be ventilated in the so-called 'natural,' as distinguished from the 'mechanical' method, by a sun-light exit shaft, and fresh air admission behind the dado. The sun-light is now replaced by pendants of electric lamps. The question is whether it is better or worse with electric lighting than when gas was solely used. We believe it is much worse; but this is a point the Society ought, in justice to itself, to set right by competent inquiry. Until this is done, and the reputation of the electric lighting is cleared, we shall continue to hold, on *prima facie* evidence, that the Society's hall is now one of the worst ventilated public rooms in all London, thanks to its electric lamps. And what is true of this hall is probably true, in degree, of many others."

**The Pacific Cable.**—We reproduce the following paragraph from the Melbourne *Herald* of November 6th:—"Once more Canada has renewed her offer to subsidise liberally any company which shall lay a submarine telegraphic cable between her Pacific coast and Australia. The advantages which would accrue to us from the construction of the line have been again and again described in the *Herald*. It would be quite out of the way of the volcanic disturbances which have so frequently broken our communications by the Eastern route. It would be very easily protected against enemies at sea, and would pass through none but British territory on shore. It would open up communications between Canada and Australia which could not fail to extend our trade, and it would give us a cheaper tariff than we at present pay. It is evident that these are all objects highly important to us. The existing lines pass through territory which may at any moment become hostile, and they are open not only to breakage by submarine eruptions but also to be fished up and broken by an enemy's vessels. In the event of a war we might neutralise the North Pacific line by inducing the United States to take over the guardianship of the cable; but no such course would be open to us with regard to the existing lines, which are quite beyond our control. Ships would presently follow the cable, and a large trade could soon be done with British Columbia. The run from Australia to Vancouver is a quick one, and a quiet one. Our seasons are the direct opposite of those of Canada, and we could sell our wines, our fruits, and many products there, which she requires, just as in return she could help us with many commodities. Assuredly, the entire subject deserves the immediate notice of the Government, who can have no grander task set them than that of drawing together the two great dependencies which between them make up Greater Britain."

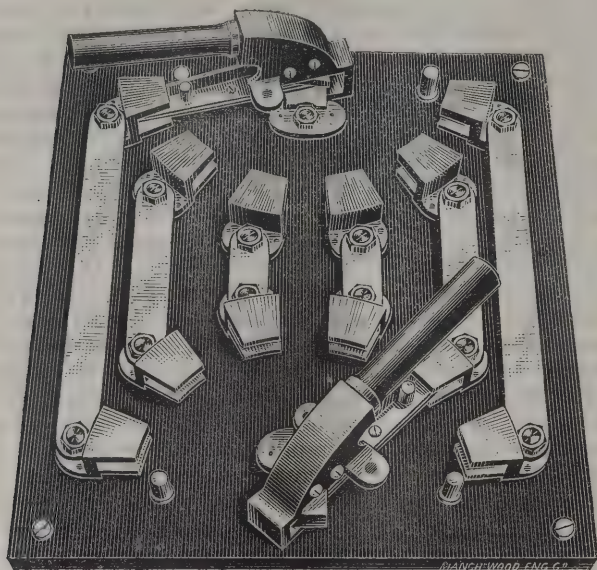

**Royal Naval Exhibition.**—The electric lighting committee, the members of which are Sir Wm. Thomson, Capt. Eardley Wilmot, R.N., Mr. E. H. Carbutt, Mr. W. H. Preece, and Mr. J. I. Thornycroft, have decided to entrust the lighting of the entire exhibition to Messrs. Siemens Bros. & Co., who will furnish the dynamos and lamps. The engines will be supplied by Messrs. Willans and Robinson, and the boilers for the electric light, as well as for the machinery in motion, will be from the well-known works of Messrs. Davey, Paxman and Co. At this initial stage, it is premature to say exactly what the extent of the lighting will be; but it is the intention of the committee to make the lighting a brilliant affair in all respects. Some 200 arc lamps and 2,000 glow lamps will probably be required to illuminate the buildings and grounds, and the dynamos will also have to supply current for several interesting applications of the transmission of power, and for the lighthouse of Messrs. Chance Bros., which will form one of the features of the exhibition.

**Handy Lists of Technical Literature.**—We have received from M. H. E. Haferkorn, of Fourth Avenue, Milwaukee, Wis., Part II.A of his publication, "Handy Lists of Technical Literature." This portion is devoted to books on electricity and magnetism, telegraph, gas, &c., and the compiler believes that this is the first attempt to catalogue the literature on electricity of the period 1880 to October, 1890, in a practical and time-saving way. Everybody interested in this steadily growing branch of study would readily appreciate Mr. Haferkorn's "handy list" as a guide in searching for books on special subjects.

**The Henley Companies.**—Meetings of Henley's Telegraph Works, Limited, and Henley's Electric Light and Power Company, Limited, were held yesterday at the offices, 27, Martin's Lane, E.C. Press representatives were refused admission.

**Electric Light in a Carpet Factory.**—The well-known carpet factory of Messrs. Henderson & Co., of Durham, has been fitted with the electric light.

**Regulator for Accumulator.**—The engraving shows Messrs. Dorman and Smith's patent regulator for use on accumulator circuits. The change in the number of cells being charged or discharged is obtained in such a

manner that the cells are never short-circuited, and the step-by-step motion is instantaneous, even when the handle is moved slowly, this result being obtained in a simple manner, without triggers or complications.

**Mechanics' Almanac.**—A useful workshop companion is Calvert's Mechanics' Almanac, 1891, being the eighteenth year of its publication. It contains a large amount of information specially interesting to artisans and handicraftsmen, illustrated with diagrams.

**A Committee on Electrical Standards.**—The President of the Board of Trade has appointed a committee consisting of the following gentlemen, viz. :—

Lord Rayleigh, F.R.S.	{	Representing the Royal Society.
Sir William Thomson, F.R.S.		
Prof. G. Carey Foster, F.R.S.	{	Representing the British Association for the Advancement of Science.
R. T. Glazebrook, Esq., F.R.S.		
Dr. John Hopkinson, F.R.S.	{	Representing the Institution of Electrical Engineers.
Prof. W. E. Ayrton, F.R.S.		
E. Graves, Esq.	{	Representing the General Post Office.
W. H. Preece, Esq., F.R.S.		
Courtenay Boyle, Esq., C.B.	{	Representing the Board of Trade.
Major P. Cardew, R.E.		

to consider whether any and, if so, what steps should be taken for the provision of electrical standards. The first meeting of the committee will be held at the Board of Trade on Thursday, the 15th of January. Sir Thomas Blomefield, of the Board of Trade, will act as Secretary to the committee.

**New York Subways.**—We extract the following paragraph from a letter which reached us this morning from the States :—"In spite of all the public outcry in New York City, the subways are very little used. The companies interested in electric leads give as an excuse the extravagant rent charged for use of the subways; the latter are owned or controlled by the "Western Union" and "Bell Telephone," so it is easy for them to have the rent for use fixed to suit themselves.

**Share List.**—Pressure on our space prevents us publishing the usual share list this week; but we observe the following changes from last Thursday's prices :—Consolidated Telephones were quoted at from  $\frac{1}{2}$  to  $\frac{5}{8}$ , Elmore's Coppers have gone up and stand at from  $4\frac{1}{4}$  to  $4\frac{3}{4}$ , and Westminster Electric Supplies stand at from  $2\frac{1}{2}$  to 3.

**The Chelsea Electricity Supply Company and the Vestry.**—At the last meeting of the vestry, a letter was read from the Chelsea Electricity Supply Company, giving notice of the intention to discontinue the supply of electricity between the hours of midnight and 4 o'clock in the afternoon, and stating that this was a temporary measure made necessary by the continuance for several days of heavy fogs. Mr. H. J. Wright complained bitterly, as a consumer, of this proposal. He stated that the company had already cut off the supply, and on Saturday morning he was without any light at all. He moved that as the company are applying for a further extension of their order of supply, the Board of Trade should be asked to refuse their assent to such application, unless they would compel the company to give a continuous supply, night and day, even during the foggy weather. After further discussion, in which strong things were said, the motion was carried.

**Telephone Management.**—Mr. George J. Summer-ville, who has been manager for the National Telephone Company in the Aberdeen district for the past six years, has been appointed district manager to the Mutual Telephone Company for Lancashire.

**The Belgian Society of Electricians.**—The Belgian Society of Electricians began, on December 4th, its series of public Thursday lectures, on the premises of the Engineers' Society at the Palais de la Bourse, Brussels. The President, M. Wybauw, in a short opening address, set forth the great change which electricity had imported into the study of all the sciences, and how necessary it was for the engineer, with whichever branch he was connected, to keep himself *au courant* with the researches of which this relatively new science was the object. By starting public lectures given by its members, the Belgian Society of Electricians was endeavouring to meet a real want and to facilitate to all the study, longer or shorter, of electricity and its most frequent applications. The lecturer, Capt. Eugène Lagrange (of the Engineers), a professor at the Military School, afterwards gave, with much clearness, an interesting history of electrical science. This lecture, which was embellished with numerous anecdotes, highly interested those present, and formed a promising beginning for the course. The following ones will be accompanied by experimental demonstrations, which cannot fail to add to their success.

**City and South London Railway.**—A correspondent has taken the trouble to send us the following figures :—"Trains every five minutes both ways = 168 trains per day of 14 hours. Fare 2d., average 50 passengers =  $365 \times 168 \times 2 \times 50$

$$\frac{240}{240} = \text{£}25,134, \text{ or gross revenue, say, } \text{£}25,000 \text{ per annum.}$$

On ordinary railways (steam) the expenses are 50 per cent. of the revenue. If this applies to the above the profit may be, with three million passengers per year and a twopenny fare =  $\text{£}12,500, \text{ or } \frac{12,500}{760,000} = 1.8 \text{ per cent. on capital.}$ " Our

correspondent has only based his calculations on one line; he has omitted the return trains, but, on the other hand, his average of 50 passengers on a total train capacity of 100, will be found too high when the company once gets into ordinary everyday work. Perhaps others of our readers may have figured out the probable chances of dividend paying on £760,000 sunk capital?

**Elmore's Foreign and Colonial, &c., Company.**—To everybody interested in this concern we recommend the perusal of a letter signed "Vigilans," which appeared in Tuesday's issue of the *Financial Times*.

**Another Trans-Continental Wire.**—The Western Union has a new wire between San Francisco and New York almost up. It is a Wheatstone automatic circuit, and is intended for California through business exclusively.

**Who is Henry Hickman?**—We extract the following from the *Financial Times* of Monday:—Would Mr. William Elmore have any objection to tell us precisely who is "Henry Hickman, engineer, 51 and 53, Handforth Road, London, S.W.?" We are curious to know, because Mr. Hickman holds 4,660 shares in MacIvor's Patents, Limited, and because he took the trouble to write to us to assert his perfect confidence in the MacIvor process, citing his large holding as proof of his faith. But when Mr. Henry Hickman is written to at the address he gives in the register of shareholders, and which he gave to us, the Post Office returns the letter marked, "No such number, and name unknown in Handforth Road, Stockwell, S.W." Can Mr. Hickman be produced, and, if he can, why does he not give an address that can be traced? Perhaps Mr. Elmore will explain, as we are not disposed to pay much heed to Mr. Henry Hickman's communications.

**Electric Lighting Complaints.**—Mr. R. Chamberlain returns to his attack on the Chelsea Electricity Supply Company, and states that during the recent foggy weather, the potential difference at the lamp terminals has been less than 90 volts. Naturally this leaves one's house very badly lighted, and the chairman of the company attempts to show that the recent continuous fogs have drained the reserves of electricity in the accumulators. He omits to say, however, that this excuse is invalid, because the dynamos ought to be able to supply all the maximum current required at any period. It appears to us that the great drop in E.M.F. shows that at the time of maximum demand the leads are too small, and that sudden strains upon the output of the station, such as now exist, had not been allowed for. To the extraordinary notice which the company has thought it advisable to issue, we refer in our leading columns.

**Crystal Palace School of Engineering.**—The certificates gained by the students of the Crystal Palace School of Practical Engineering during the past term were presented on Saturday afternoon, in the lecture room of the school, by Major F. A. Marindin (Inspector of Railways), who, in the course of his address to the students, specially referred to the large field opening up for engineers in the direction of electricity, "the future of which no one could foretell, and the importance of which it was almost impossible to exaggerate." The results of the examinations showed that the school was advancing in numbers, and, as in past terms, had been distinguished, not more by the ability and energy of the teachers, than by the great earnestness of the students.

**A Lost Opportunity.**—*Modern Light and Heat* says: "It is astonishing by what narrow margins some people escape making large fortunes. It is reported that Prof. Alexander Graham Bell tried again and again to persuade Senator Don Cameron to buy a one-half interest in his invention for \$10,000. Cameron thought Bell a half-witted dreamer, refused to put up a dollar, and finally gave orders that Bell should no longer be admitted to his office. That half-interest to-day would pay a handsome interest of \$10,000,000."

**Reuter's Telegram Company, Limited.**—A meeting was to be held yesterday for the purpose of confirming the resolutions passed at the meeting held on December 6th, and reported in our issue of December 12th.

#### TRAFFIC RECEIPTS

The Brazilian Submarine Telegraph Company, Limited. (The traffic receipts for the week ending December 19th were £6,118.)

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending December 19th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited were £4,815.

#### NEW COMPANIES REGISTERED.

**Electric Stores, Limited.**—Capital, £15,000 in £1 shares. Objects: To carry on, either as principals or agents, the business of electrical stores, and for the manufacture and sale of electric, telegraphic, surgical, and scientific instruments. Signatories (with 1 share each): A. L. Martyn, L.R.C.P.L., Saltash; J. R. Davies, 29, Stockwell Park, S.W.; J. R. Davis, Greenwood Road, N.E.; H. R. Pope, Streatham; G. Grant Lobham, 33, Mornington Road, Regent's Park; T. V. Riodan, Cantley House, Clapham Common; R. S. Jennings, Capel Road, Forest Gate. Registered 17th inst., without special articles, by G. D. Freeman, 103A, Paul Street, Finsbury Square. Registered office, 51, Cannon Street.

**New Zealand Electrical Syndicate, Limited.**—Capital, £30,000 in £10 shares. Objects: To acquire charters, concessions, and other privileges for the production, storage, and distribution of electricity in New Zealand, Victoria, New South Wales, North, South or Western Australia, Tasmania, New Guinea, the Fiji Islands, or elsewhere in Australasia, and to take over and work the central stations erected by the Gülcher (New) Electric Light and Power Company, Limited, in Wellington, New Zealand. Signatories (with 1 share each): \*Daniel de Castro, 6, New Square, Lincoln's Inn; Walter Turnbull, Mount Henley, Sydenham Hill; R. Pryor, 79, Gracechurch Street; \*M. S. Vanderbyl, 187, Queen's Gate; \*H. Gröwing, 14, Austin Friar's; James Alexander, 3, Great Winchester Street; W. Farmer, 48, Aldermanbury. The signatories denoted by an asterisk, and J. Evelyn Williams, are the first directors. Registered 20th inst. by Reyroux, Phillips & Co., 99, Cannon Street.

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Nottingham Electric Light and Power Company, Limited.**—The annual return of this company, made up to the 8th inst., was filed on the 18th inst. The nominal capital is £100,000, divided into 9,900 ordinary and 100 founders' shares of £10 each. The shares taken up are 27 founders' and 200 ordinary, but no call has been made, or paid, in respect thereof. Registered office, 22, Low Pavement, Nottingham.

**Electric Trust, Limited.**—By a resolution passed by this company in general meeting on the 10th inst., the capital of the company has been increased by the addition thereto of £200 divided into 200 shares of £1 each, beyond the registered capital of £60,000.

**Woolwich District Electric Light Company, Limited.**—The statutory return of this company, made up to the 17th inst., was filed the same day. The nominal capital is £10,000 in £1 shares; 180 shares are taken up, the full amount has been called thereon, the calls paid amounting to £140 and unpaid to £40. Registered office, 39, William Street, Woolwich.

**Bishop Stortford Electric Light and Steam Laundry Company, Limited.**—The statutory return of this company, made up to the 17th inst., was filed on the same day. The nominal capital is £10,000 in £1 shares; 11 shares have been taken up, and the full amount has been called thereon, but not paid. Registered office, North Street, Bishops Stortford, Herts.

**Swan United Electric Light Company, Limited.**—The annual return of this company, made up to the 9th inst., was filed on the 17th inst. The nominal capital is £1,000,000 in £5 shares; the shares taken up are 78,949 ordinary, and 19,750 considered fully paid; upon the former the sum of £3 10s. per share has been called, the calls paid amount to £279,851 10s. The sum of £3,530 has been paid upon 1,201 shares forfeited.

# RULES AND REGULATIONS OF THE NEW ENGLAND INSURANCE EXCHANGE FOR ELECTRIC LIGHTING.

ADOPTED SEPT. 27TH, 1890, AND SUPERSEDING ALL PREVIOUS  
RULES.

*Revised in Conjunction with Committee from New England  
Electric Exchange.*

## GENERAL REQUIREMENTS.

A CERTIFICATE for all new work or changes in old work (Form "C" for arc, Form "F" for incandescent), should be signed by the party installing or controlling any apparatus. The certificate should be filed with the Secretary of the Local Board of Fire Underwriters having jurisdiction, if there be such; otherwise, with the Secretary of the New England Insurance Exchange, Boston.

This certificate is relied upon as a guaranty until the work can be inspected. Permits for the use of the light or power may be granted as soon as the certificate is duly filed.

Blank certificates may be obtained by application to the Secretary of the New England Insurance Exchange, Boston.

All work should be inspected before any of it is concealed, and to this end notice of concealed work must be given this exchange as soon as work is commenced.

The New England Insurance Exchange reserves the right at any time to add to, change, or modify the accompanying rules, and to enforce such modifications, changes, &c., as it shall deem necessary for safety; and it will use all reasonable efforts to promptly notify all electric light companies of any such change.

Any additional loading of wires, either in a building as a whole, or in any department thereof, without previous notification to the exchange, such as is required, shall be deemed a sufficient cause for the suspension of any permit previously granted, until the same shall have been inspected and approved by this exchange.

This exchange reserves the right to disapprove of the use of any wire, switch, cut-out, or any device, or form of material, which it may consider inconsistent with safety from fire risk, even though it may be proposed to instal the same in conformity with these rules.

The following rules will be strictly enforced, and in no case will a certificate of inspection be issued for work which does not fully comply with the rules in all particulars.

## RULES FOR WIRING.

### *Outside Wires.*

1. Conducting wires carried over or attached to buildings, must be (a) at least 7 feet above the highest point of flat roofs, and (b) 1 foot above the ridge of pitch roofs; (c) when in proximity to other conductors likely to divert any portion of the current, they must be protected by guard irons or wires, or a proper additional insulation, as the case may require.

2. For entering buildings, (a) wires with an extra heavy waterproof insulation must be used, (b) they must be protected by drip loops, (c) also protected from abrasion by awning frames (d) be at least 6 inches apart, (e) the holes through which they pass in the outer wall of such building must be bushed with a non-inflammable, waterproof, insulating tube, and (f) should slant towards the inside.

3. The inspector may, at his discretion, require wires, other than those used for conveying current for electric light or power, entering buildings to be protected by some approved automatic cut-out, in any locality where such wires are, in his opinion, liable to come in contact with electric light or power wires.

4. Converters, and the primary wires leading thereto, (a) must not be placed inside of any building (central stations excepted); (b) they may be attached to the walls on the outside if securely supported by substantial wooden cross pieces or cleats.

5. Wires attached to buildings should be (a) free of contact with the building, and (b) supported by rubber hooks, glass insulators, or porcelain knobs. (Porcelain knobs should be used to support high potential wires.)

### *Inside Wires.*

[High Potential (over 350 volts) Arc and Series Incandescent.]

6. Wires must enter and leave the building (a) at the same place (b) through an approved cut-out switch, which must be (c) mounted on a non-combustible base if attached to any combustible substance (d) kept free from moisture, and (e) easy of access to firemen and police.

7. The cut-out switch must be (a) double-contact (b) must effectually close the main circuit and cut off the interior, when turned "off" (c) so constructed that there shall be no arc between the points when thrown "on" or "off" (d) automatic in its action (not stopping between points when once started) (e) and indicate upon inspection whether the current be "on" or "off."

8. Wires (a) must be rigidly supported (b) on porcelain, glass, or other non-combustible insulators (c) free from contact with the building, (d) have water-proof insulation wherever there is a possible exposure to moisture, (e) be at least 12 inches apart, and (f) at least 3 inches from any other substance capable of acting as a conductor.

9. (a) When wires pass through walls, floors, partitions, &c., (b) or wherever protection from mechanical injury is necessary, (c) they must be protected by glass, hard rubber, or other moisture-proof, non-inflammable tubing. (d) Soft rubber tubing will not be approved.

10. (a) No concealed work (b) or wires fastened with metallic staples will be approved.

11. In perfectly dry places wires (a) supported by wooden cleats, which (b) are "filled" to prevent the absorption of moisture, and (c) have a backing so as to separate the wire at least one-fourth inch from the building, may be approved by the inspector.

12. A wire (a) having a non-inflammable insulation, and (b) be enclosed in a moisture-proof (c) insulating conduit or tubing (d) sufficiently strong to protect the wire from mechanical injury, may be used, in which case the tube may be fastened by metallic loops if desired, and the distance between wires reduced to 3 inches; but (e) the entire "conduit system" must be moisture-tight—i.e., joints and open ends must be sealed with some approved cement.

13. The "series" incandescent lamp must (a) be provided with a proper hand-switch, and (b) an approved automatic device which will shunt the circuit around the carbon filament should it break; (c) it must be suspended from a hanger board by means of a rigid tube, and (d) must not be used in damp or wet places.

14. Any method of distributing current to incandescent lamps on high potential circuits other than as above provided for, must receive the approval of this exchange before being put into use.

15. In arc lamps indoors, (a) the light must be surrounded by a globe with a closed base; (b) the depth of the globe must be such that the point of contact between the carbons, when the lamp is newly trimmed, shall not be less than 3 inches below the upper edge of the globe; and (c) the globe must be enclosed by a wire netting where there is any material under the lamp that could be damaged or ignited by hot cinders, or (d) when the lamp is an "all night" lamp. (e) Where exposed to flyings, or where any inflammable material is suspended near the lamp, spark arresters must be used.

16. Hanger boards for arc or series incandescent lamps must not be used in damp places or wet places.

17. Each arc lamp must be provided (a) with a proper hand switch, (b) with an automatic switch that will shunt the current around the carbons should they fail to feed properly, and (c) with "stops" to prevent the carbons from falling out in case their clamps fail to hold them.

18. The entire installation must test free from grounds.

[Low potential (350 volts or less) incandescent.]

19. For inside work, no wire smaller than No. 14 "B. and S.," or No. 16 "B.W.G.," will be approved.

20. Samples of wire to be used, or in actual use, must be submitted to this exchange, for tests of conductivity or of insulation, at any time when required.

21. (a) Wires must never be left exposed to mechanical injury, or to disturbance of any kind. (b) Wires must not be fastened by metallic staples. (c) When wires pass through walls, floors, partitions, timbers, &c., glass tubing, or so-called "floor insulators," or other moisture-proof, non-inflammable, insulating tubing must be used. (d) At all outlets to and from cut-outs, switches, fixtures, &c., wires must be separated from gas pipes or parts of the building by porcelain, glass, or other non-inflammable insulating tubing, (e) and should be left in such a way as not to be disturbed by the plasterers. (f) Wires of whatever insulation must not in any case be taped or otherwise fastened to gas piping. (g) If no gas pipes are installed at the outlets, an approved substantial support must be provided for the fixtures.

22. In crossing any metal pipes, or any other conductor, (a) wires must be separated from the same by an air space of at least  $\frac{1}{8}$  inch, where possible, and (b) so arranged that they cannot come in contact with each other by accident. (c) They should go over water pipes.

23. Twin wires must not be used except (a) as allowed in "conduit" wiring, (b) or for "pendants," fixture wiring, and "portables." (c) An exception may be made to this rule, by the inspector, where it is necessary to run a short distance, if the wire (d) has a non-inflammable covering, (e) is not concealed, and (f) carries but a small current.

24. The safe carrying capacity of wires when exposed to the air may be taken from the following table:—

B. and S. gauge.	Current in amperes.
0000	300
000	245
00	215
0	190
1	160
2	135
3	115
4	100
5	90
6	80
7	67
8	60
10	40
12	30
14	22
16	15

When wires are enclosed in moulding or otherwise treated so as to prevent cooling by radiation, the carrying capacity is reduced

about 40 per cent., and under such circumstances, or when the wires are installed where the temperature is unusually high, as in boiler rooms, and the like, wires should be fused accordingly.

25. (a) In rooms where inflammable gases may develop, or (b) where the atmosphere is very damp, the incandescent lamps should be enclosed in vapour-tight globes. (c) Switches are not permitted in places filled with inflammable gases, breweries, distilleries, &c., as the spark at make or break might cause explosion. (d) Fusible safety plugs, if necessary in such places, must be enclosed in air-tight, non-combustible cases.

26. Soft rubber tubing will not be approved in cases where these rules require an additional covering to the insulation of the wire.

27. The entire installation must test free from grounds.

#### WIRING.

##### Cleat Work.

28. (a) Cleats made of well-filled, dry, hard wood may be used to support wires not concealed, in perfectly dry places only. (b) They must be so constructed as to separate wires of opposite polarity at least  $2\frac{1}{2}$  inches. (c) Wires must be drawn taut, and cleats placed near enough together to prevent the possibility of contact between the wires.

29. Except on wooden surfaces so filled as to prevent the absorption of moisture (a) the wire must have a waterproof insulation, or (b) the cleats must have a backing that will separate the wire at least  $\frac{1}{4}$  inch from the building.

##### Moulding.

30. Mouldings must not be used (a) in concealed work, nor (b) in places where there is any probable exposure to moisture.

31. (a) Moulding must consist of two parts: viz., a back-piece, which shall separate the wire at least one-fourth inch from the part of the building to which it is fastened, and a cover, one of which parts shall contain the grooves, (b) these grooves to have between them a septum or tongue of wood so as to separate the wires at least one-half inch. (c) The moulding must be coated inside and out with shellac or water-proof paint, or treated in some other manner so as to prevent any possible absorption of moisture. (d) Mouldings with open grooves laid against walls or ceilings will only be approved when such walls or ceilings are of wood, and so filled as to prevent the absorption of moisture.

##### Concealed Work.

32. In unfinished lofts, between floors and ceilings, in partitions, and other concealed places, wires must (a) be kept free of contact with the building, (b) be supported on glass, porcelain, or other non-combustible insulators, (c) have at least one inch clear air space surrounding them, (d) be at least 10 inches apart when possible, and (e) should be run singly on separate timbers or studding. (f) When thus run in perfectly dry places, and liable to be exposed to moisture, a wire having simply a non-combustible insulation may be used.

33. Wires run as above (a) immediately under roofs (b) in proximity to water tanks, or pipes, will be considered as exposed to moisture; and in such places the insulating covering of the wire must consist of a water-proof covering next the wire, protected by an external covering not easily abraded, and that will not support combustion.

34. Wires must not be fished (a) for any great distance, and (b) only in places where the inspector can satisfy himself that the above rules have been complied with. (c) Twin wires must never be employed in this class of concealed work.

##### Conduit Wiring.

35. Wires may also be concealed by means of a system of insulating tubes, or "conduits," that are moisture-proof and practically non-inflammable, and have a threaded joint. (a) A separate tube must be provided for each wire, except (b) in case of taps or branches carrying a current that does not exceed 15 amperes, in which case a flexible twin cable may be used; but (c) the two conductors of this cable must not be insulated from each other by a rubber compound. A cotton or other fibrous covering should be used, and (d) the joints between sections must be made moisture proof, with some cement proper for the purpose; i.e., the whole system must be free from joints, cracks, &c., where it would be possible for moisture to enter the tubing.

36. These tubes may be secured by metallic loops, and may be laid side by side.

37. This is the only manner in which wires may be run imbedded in plaster, cement, or any similar material. Wires run on brick walls or below timbers furred for lath and plaster will be considered as imbedded in plaster, unless the furring strips are of such thickness as to prevent any contact between the wire and the clinches of plaster.

##### Wires in Damp Places.

38. In dye houses, paper and pulp mills, and other buildings especially liable to moisture, all wires, except those used for pendants, must (a) be separated at least 6 inches, (b) be thoroughly and carefully put up, and (c) be supported by glass or porcelain insulators, or by rubber hooks.

39. Where it is necessary to run the wires down a side wall in order to pass through a floor, the wires must (a) be supported from the ceiling to the floor on insulators, (b) placed, if necessary, on a back board, and (c) to protect the wires from injury, they should be boxed over from the floor to a point 5 or 6 feet above.

40. Where exposed to acid fumes, vapors of ammonia, &c., wires should (a) be provided with an insulation, and (b) supported on insulators that will not be injured thereby.

In places covered by Rules 38 and 40, wires may be run under rules for "conduit" wiring, and if to be concealed they must be so run, but in either case will be subject to special approval by the inspector.

#### FITTINGS AND APPARATUS.

##### Safety Cut-outs.

42. (a) Every portion of each installation must be equipped with safety cut-outs, that will interrupt the passage of a current in excess of the amount which that portion of the apparatus is adequate to transmit. (b) Fusible leads designed to carry a current of 10 amperes or over must have contact surfaces of some harder material. (c) Fusible leads should be proportioned to the capacity of the wire they are to protect, and not to the number of amperes required to supply the lamps on that particular circuit. (d) A cut-out must be placed where the underground or overhead service joins the inside wires, and (e) at every point where a change is made in the size of the wire (unless the cut-out in the larger wire is intended to protect the smaller). (f) A cut-out must be provided for each fixture, and (g) in concealed wiring, for each pendant also; but (h) where the wires are exposed, one cut-out may be employed to protect two or more pendants, provided (i) the amount of current they require does not exceed 7 amperes. (j) Stiff brackets not attached to gas pipes may be treated as pendants in this connection.

43. All cut-out devices must (a) be made of non-combustible material, and (b) be placed so as to protect both sides of the circuit, and (c) be provided with close-fitting covers.

44. When lights are grouped, as upon electroliers, &c., the small wires to each light cannot always have cut-outs. Care should be taken, however, that the least controlling cut-out (a) carries as small an amount of current as practicable, and (b) that it will act before the smallest wire runs any risk of being unduly heated.

##### Switches.

45. All switches must (a) be composed entirely of non-combustible material, and (b) be automatic in action.

46. All switches must be double-pole, in circuits (a) connected to fixtures attached to gas pipes, or (b) carrying a current of 10 amperes or over.

##### Pendants, Portables, &c.

47. (a) Lamps may be suspended by flexible cord pendants not less than No. 16 B. and S. or No. 18 B.W.G. (b) Where it enters the lamp socket, the cord must be protected by a bushing of rubber, wood, or some similar insulating material, and (c) the cord must be so arranged that the weight of the lamp, &c., shall not be borne by the joints or binding screws.

48. (a) The covering of the flexible cord, as a whole, shall be of such a nature that it will not support combustion, (b) in damp places the cord must have a moisture-proof covering, and (c) the openings at the top of the socket must be closed, so as to prevent the entrance of water. (d) The flexible leads of the portable fittings must in all cases be protected by cut-outs at their fixed points of connection.

##### Fixtures.

49. (a) Each fixture to which wires are attached must be insulated from the piping of the building by an insulating joint. (b) Burrs and sharp edges must be removed before wires are drawn into a fixture. (c) Wires attached to, or concealed within fixtures, must have an insulating covering that cannot be easily cut or abraded, and (d) that is moisture proof; (e) where attached to the outside of a gas fixture, the conductors must be so secured that their covering will not be cut or abraded by the swaying of the fixture or the movement of the bracket arm. (f) The difference of potential between any two wires connected with a combination or gas fixture, must not exceed 125 volts. (g) No wire smaller than No. 16 B. and S. or No. 18 B.W.G. must be used in fixture wiring.

##### Electric Gas Lighting.

50. Where electric gas lighting is to be used on the same fixture with the electric light (a) no part of the gas piping or fixture shall be in connection with the gas lighting circuit; (b) the wires used for the fixture must have a non-inflammable insulation, or (c) if concealed between the pipes, and a shell of the fixture, must have an insulation such as is required for fixture wiring for the electric light; (d) the whole installation must test free of grounds, and (e) the two installations must test perfectly free of connection with each other. (f) Any such installation will then be subject to special approval by the inspector.

##### Arc Lights on Low Potential Circuits.

51. This system of lighting will in general be governed by the foregoing rules for low potential work, but (a) no wire smaller than No. 12 B. and S. must be used; (b) there must be a double pole cut-out at the junction of the branch with the main, and (c) a double pole switch in the branch. (d) The cut-out, switch, and resistance device must be composed of non-inflammable material. (e) The light must be protected by a globe, &c., the same as is required for a high potential lamp.

## ISOLATED PLANTS.

52. In isolated plants, (a) the dynamo, regulating devices, switchboards, and all wires connecting the same, must be installed in conformity with the requirements for a standard central station (see 53 to 67), and (b) should never be placed in any room where they will be exposed to flyings of any combustible materials.

*Dynamos.*

53. (a) Insulated on thoroughly dry wood, (b) "filled" to prevent absorption of moisture. (c) A waterproof cover should be provided, and kept over each dynamo when not running.

*Wires.*

54. (a) Wires from dynamos to switchboard, and (b) thence to outside lines (bus wires, feeders, primary mains, arc circuit leads and returns) (c) to be wholly exposed to view (d) supported by glass or porcelain insulators, and (e) of sufficient sectional area to prevent heating. (f) Where passing through floors, partitions, or other woodwork, (g) to be protected by substantial tubes of glass or porcelain, (h) which shall project above and below floors, and beyond the surface of partitions, so as to insure perfect insulation. (i) Hard rubber tubing may be used, except where passing through the floors at or near the dynamo.

55. (a) Where leaving the building, the wires to be looped downward, and (b) the tubes in which they are enclosed to be inclined so as to prevent the entrance of rain water along the wires.

56. (a) Wires of opposite polarity should be separated at least 12 inches, (b) particularly where passing through floors and partitions. (c) Conductors from ceiling or floor to switchboard may be run at less distance than 12 inches from each other, (d) but in that case an approved insulation must be provided.

57. If (a) conductors from dynamos are run under floors, (b) except the space underneath be a perfectly dry finished room, and (c) not less than 6 feet between floors, (d) they must be specially insulated and will then be subject to approval.

58. (a) Each feeder and primary main to be provided with a safety fuse on a non-combustible base. (b) All wire connections must be soldered, if necessary, to secure good contact.

59. Branch wires for station lighting to be in accordance with the requirements of this exchange for electric light wiring.

*Switchboards.*

60. (a) To be kept free from moisture (b) located apart from wood work (c) accessible from all sides (d) not enclosed, and (e) with all electrical devices, wires and connections in plain sight. (f) When all wires and electrical devices are on the front, the switchboard may be set against a brick wall (g) but must be detached from any wood work. (h) The switchboard should be constructed either of slate or some other non-combustible insulating substance, or (i) so-called "skeleton."

61. (a) All switches and wires on the switchboard must have ample capacity and (b) contact to carry their possible maximum load without heating.

*Lightning Arresters.*

62. (a) To be located in sight of attendants, and (b) so placed and constructed that an arc if formed will not come in contact with wood work or other combustible material. (c) Lightning arresters should be so designed as to automatically destroy any arc which may be formed by a lightning discharge or otherwise.

*Equalisers.*

63. (a) Frames to be constructed of non-combustible material. (b) To be open and accessible from all sides (c) supported at least 12 inches from all wood work (d) and located so as to be in sight of dynamo attendant.

64. (a) All resistance devices to be so designed as to heat but slightly when in use, and (b) connected so as not to be liable from a short circuit or other cause to an over charge of current; (c) otherwise they must be enclosed in non-combustible cases and (d) kept away from any woodwork.

*Care and Attendance.*

65. A competent man must be kept constantly in the dynamo room while the dynamos are running.

66. (a) Oil must not be allowed to accumulate on the floor, and (b) all oily waste must be kept in standard metal waste cans, or (c) removed from the station daily after the dynamos are stopped and cleaned.

67. Arc lamps must always be provided with perfect globes.

## MOTORS.

68. Motors must (a) be placed as near as possible to the point where wires enter the building (b) be mounted on filled, dry wood, (c) be raised at least 8 inches above the surrounding floor, (d) be kept clean, and (e) covered with a waterproof cover when not in use, and (f) if deemed necessary by the inspector, be enclosed in an approved case.

69. Standard metal waste cans, with a self-closing cover and legs raising the can at least 3 inches from the floor, must be provided for oily waste.

*Switches, Regulators, and Cut-outs.*

70. (a) The controlling switch must be so constructed as to entirely disconnect the motor from the circuit, and (b) a cut-out such as is required for a similar lighting circuit must be placed

as near as possible to the point where the wires enter the building.

71. All switches, regulators, cut-outs, &c., must (a) be as nearly non-combustible as possible, (b) be protected from moisture, (c) have a backing of porcelain, slate, cement, asbestos, or other equally non-combustible substance, and (d) be perfectly insulated.

*Wiring.*

72. (a) Wire having a waterproof insulation must be used. (b) The wire must be rigidly supported (c) on porcelain, glass or other non-combustible insulators, free from contact with the building, and (d) at least 6 inches apart. (e) No concealed work, (f) cleat work, or (g) wires fastened with metallic staples, will be approved.

73. (a) when wires pass through walls, floors, partitions, &c., or (b) wherever protection from mechanical injury is necessary, (c) they must be protected by glass, hard rubber, or other moisture proof, non-inflammable tubing. (d) (Soft rubber tubing will not be approved.)

74. These rules are not intended to preclude the running of small motors (for fans and the like) on low potential lighting circuits, the installation of which has received the approval of the inspector.

75. The entire installation must test free from grounds; but motors run on a "ground circuit" may be approved by the inspector, under these rules, provided the return wire is carried to a ground outside of the building.

## LIGHTING FROM GROUND RETURN POWER CIRCUITS.

76. Electric railway power stations and their car sheds may be lighted by incandescent lamps connected with their power wires, if the installation of the wires meets with the approval of the inspector, but no other property may be so lighted.

## MISCELLANEOUS.

77. Splices in both arc and incandescent circuit wires must be made so that a perfectly secure and unvarying connection, fully equal to the cross section of the wire will be secured. The splice must be soldered, but solder must never be employed to complete a joint that would be loose or insecure without it. Either resin or an acid solution may be used as a flux; both are objectionable if not carefully applied.

78. Architects are urged to familiarise themselves with these rules, and to see that all contracts are made subject to the work being done in accordance therewith, and also to see that it has so done. The New England Insurance Exchange will gladly aid them to this end by giving information, advice, or inspection to as great an extent as possible.

79. A great danger in all installations is from poor contacts; consequently, avoid screw joints as much as possible; screw them up tight, with good areas of contact; on no account allow them out of sight. Solder every connection as far as practicable.

80. When an electrical fire breaks out, turn off the current at the nearest switch, or sever the conductors (one at a time); then use your appliances. The injudicious use of water without these precautions may only increase the extent of the fire. In severing the conductors of high electromotive force, be careful that you stand on a good insulator, such as dry wood, and that the handle of your hatchet is dry, or personal injury may result.

## PROCEEDINGS OF SOCIETIES.

## Physical Society.—December 12th, 1890.

Prof. W. E. AYRTON, President, in the Chair.

Mr. SHELFORD BIDWELL, F.R.S., showed "Some Experiments with Selenium Cells." The crystalline variety of selenium was, he said, most interesting to physicists owing to its electrical resistance being greatly diminished by light. This property was shown experimentally with different forms of cells, the construction of which were explained. The form recommended was that in which two copper wires are wound near each other round a slip of mica, and the spaces between the wires filled with selenium. The wires form the terminals of the so-called "cell," which, before being used, is annealed for several hours at a temperature above 200° C. Many such cells were made in 1880, 1881, and their sensitiveness to light remained unimpaired during 1882. In 1885, however, several were found less sensitive, and others totally useless; only one out of thirteen retained its sensibility till September, 1890. The loss of sensitiveness Mr. Bidwell believes due to an excessive amount of selenide of copper being formed, for although some selenide is essential to the satisfactory working of the cell, too much is fatal to its action. The selenide of one defective cell was electrolysed, red tufts of amorphous selenium appearing on the anodes. A white substance resembling moist calcium chloride was also present; this he believed to be oxide or hydroxide of selenium. Small polarisation currents had been obtained from selenium cells.

A lecture apparatus illustrating the properties of selenium cells was exhibited. It consisted of a cell connected in series with a relay and a battery. The relay was arranged so that it might

either ring a bell or light an incandescent lamp. When the bell was joined up, it remained silent so long as the selenium cell was illuminated, but on screening the cell, the bell rang. By using various coloured glasses as screens, the effect was shown to be due to the red and yellow rays. A similar experiment with the glow lamp was very striking, for, on turning down the gas lamp illuminating the cell, the electric lamp lighted, and was extinguished on turning up the gas. This demonstrated the possibility of an automatic lamp-lighter which would light or put out lamps according as they are required or superfluous. Amongst the other practical applications suggested were, announcing the accidental extinction of railway signal lamps or ships' lights, and the protection of safes and strong rooms.

Prof. MINCHIN said he had lately constructed cells of a different kind to those shown by Mr. Bidwell, and found that they gave an E.M.F. when exposed to light. For his purposes the long annealing, &c., were quite unnecessary, and a complete cell could be made in 10 minutes. One of his cells gave an E.M.F. of over 1 volt as measured by an electrometer, by the light of a fog. Their promptness of action falls off in a day or two, but if they are kept on open circuit, a week has no effect on the final E.M.F. On closed circuit, however, they deteriorate.

Prof. S. U. PICKERING said both oxides of selenium were deliquescent, and the author's conclusion as to the white substance formed by electrolysis was probably correct.

Prof. S. P. THOMPSON believed Prof. Graham Bell had tried platinum instead of copper, and found that the selenium cracked off in annealing. He also found that it was only necessary to carry on the annealing until the characteristic slate colour appeared. Mr. Bidwell's experiments, he said, showed the possibility of seeing at a distance, and had also suggested to him that the effect of screening might be utilised for driving a completely detached pendulum electrically.

Prof. FORBES said that silver sulphide, when electrolysed, presented appearances resembling those noticed by Mr. Bidwell in copper selenide.

In reply to questions from the PRESIDENT and Prof. PERRY as to whether the low resistance and unsensitiveness of old cells was due to moisture, Mr. BIDWELL said drying them had no effect, but baking restored the resistance, but not their sensitiveness. Speaking of the effect of annealing cells, he said this reduced their resistance considerably. Prof. Graham Bell, he believed, gave up using platinum because the resistances of such cells were very high.

Mr. JAMES SWINBURNE read a paper on "Alternate Current Condensers." It is, he said, generally assumed that there is no difficulty in making commercial condensers for high pressure alternating currents. The first difficulty is insulation, for the dielectric must be very thin, else the volume of the condenser is too great. Some dielectrics, 0.2 mm. thick, can be made to stand up to 8,000 volts when in small pieces, but in complete condensers a much greater margin must be allowed. Another difficulty arises from absorption, and whenever this occurs, the apparent capacity is greater than the calculated. Supposing the fibres of paper in a paper condenser to be conductors embedded in insulating hydrocarbon, then every time the condensers is charged, the fibres have their ends at different potentials, so a current passes to equalise them, and energy is lost. This current increases the capacity. One condenser made of paper boiled in ozokerite took an abnormally large current, and heated rapidly. At a high temperature it gave off water, and the power wasted and current taken, gradually decreased. When a thin plate of mica is put between tin foils, it heats successively, and the fall of potential over the air films separating the mica and foil is great enough to cause disruptive discharge to the surface of the mica. There appears to be a luminous layer of minute sparks under the foils, and there is a strong smell of ozone. In a dielectric which heats, there may be three kinds of conduction, viz., metallic, when an ordinary conductor is imbedded in an insulator; disruptive, as probably occurs in the case of mica; and electrolytic, which might occur in glass. In a transparent dielectric, the conduction must be either electrolytic or disruptive; otherwise light vibrations would be damped. The dielectric loss in a cable may be serious. Calculating from the waste in a condenser made of paper soaked in hot ozokerite, the loss in one of the Deptford mains came out 7,000 watts. Another effect observed at Deptford is a rise of pressure in the mains. There is, as yet, no authoritative relative statement as to exactly what happens, and it is generally assumed that the effect depends on the relation of capacity to self-induction, and is a sort of reso-

nator action. This would need a large self-induction, and a small change of speed would stop the effect. The following explanation is suggested. When a condenser is put on a dynamo the condenser current leads relatively to the electromotive force, and therefore strengthens the field magnets, and increases the pressure. In order to test this the following experiment was made for the author by Mr. W. F. Bourne. A gramme alternator was coupled to the low pressure coil of a transformer, and a hot-wire voltmeter put across the primary circuit. On putting a condenser on the high pressure circuit the voltmeter wire fused. The possibility of making an alternate excite itself, like a series machine, by putting a condenser on it, is pointed out.

Professor PERRY said it would seem possible to obtain energy from an alternator without exciting the magnets independently, the field being altogether due to the armature currents.

Mr. SWINBURNE remarked that this could be done by making the rotating magnets a star-shaped mass of iron.

Sir W. THOMSON thought Mr. Swinburne's estimate of the loss in the Deptford mains was rather high. He himself had calculated the power spent in charging them, and found it to be about 16 horse power; and although a considerable fraction might be lost, it would not amount to nine-sixteenths. He was surprised to hear that glass condensers heated, and inquired whether this heating was due to flashes passing between the foil and the glass.

Mr. A. P. TROTTER said Mr. Ferranti informed him that the capacity of his mains was about one-third microfarad per mile, thus making  $2\frac{1}{3}$ rd microfarads for the seven miles. The heaping up of the potential only took place when transformers were used, and not when the dynamos were connected direct. In the former case the increase of volts was proportional to the length of main used, and 8,500 at Deptford gave 10,000 at London.

Mr. BLAKESLEY described a simple method of determining the loss of power in a condenser by the use of three electro-dynamometers, one of which has its coils separate. Of these coils, one is put in the condenser circuit, and the other in series with a non-inductive resistance  $r$ , shunting the condenser. If  $a_2$  be the reading of a dynamometer in the shunt circuit and  $a_3$ , that of the divided dynamometer, the power lost is given by  $r(ca_3 - ba_2)$ , where  $b$  and  $c$  are the constants of the instruments on which  $a_2$  and  $a_3$  are the respective readings.

Prof. S. P. THOMPSON asked if Mr. Swinburne had found any dielectric which had no absorption. So far as he was aware, pure quartz crystal was the only substance.

Prof. FORBES said Dr. Hopkinson had found a glass which showed none.

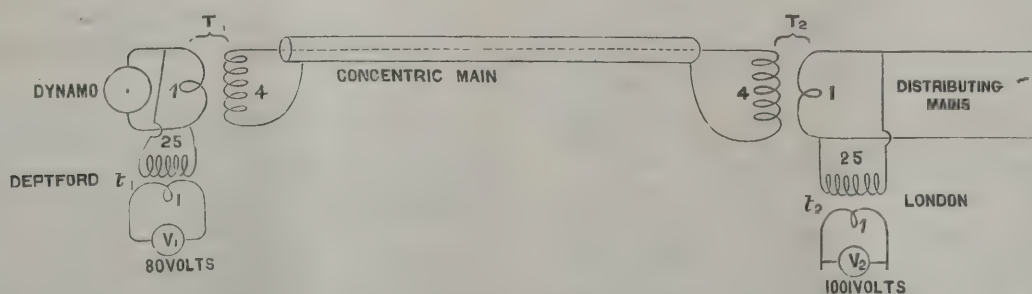

Sir W. THOMSON, referring to the same subject, said that many years ago he made some tests on glass bottles, which showed no appreciable absorption. Sulphuric acid was used for the coatings, and he found them to be completely discharged by an instantaneous contact of two balls. The duration of contact would, according to some remarkable mathematical work done by Hertz in 1882, be about 0.0004 second, and even this short time sufficed to discharge them completely. On the other hand, Leyden jars with tinfoil coatings showed considerable absorption, and this he thought due to want of close contact between the foil and the glass. To test this, he suggested that mercury coatings be tried.

Mr. KAPP considered the loss of power in condensers due to two causes; first, that due to the charge soaking in, and second, to imperfect elasticity of the dielectric. Speaking of the extraordinary rise of pressure on the Deptford mains, he said he had observed similar effects with other cables. In his experiments, the sparking distance of a 14,000-volt transformer was increased from  $\frac{1}{10}$ th of an inch to one inch by connecting the cables to its terminals. No difference was detected between the sparking distances at the two ends of the cable, nor was any rise of pressure observed when the cables were joined direct on the dynamo. In his opinion, the rise was due to some kind of resonance, and would be a maximum for some particular frequency.

Mr. MORDEY mentioned a peculiar phenomenon observed in the manufacture of his alternators. Each coil was tested to double the pressure of the complete dynamo, but when they were all fitted together, their insulation broke down at the same volts. The difficulty had been overcome by making the separate coils to stand much higher pressures.

Prof. RÜCKER called attention to the fact that dielectrics alter in volume under electric stress, and said that if the material was imperfectly elastic some loss would result.

The PRESIDENT said that as some doubt existed as to what Mr. Ferranti had actually observed, he would illustrate the arrangements by a diagram:—

Explanation of Diagram:— $T_1$  and  $T_2$  are large transformers;  $t_1$  and  $t_2$  are small transformers for voltmeters,  $V_1$  and  $V_2$ . The numbers 1, 4, 1, 25, represent their conversion ratios.

Speaking of condensers, he said he had recently tried lead plates in water to get large capacities, but, so far, had not been successful.

Mr. SWINBURNE, in replying, said he had not made a perfect condenser yet, for although he had some which did not heat much, they made a great noise. He did not see how the rise of pressure observed by Mr. Ferranti and Mr. Kapp could be due to resonance. Mr. Kapp's experiment was not conclusive, for the length of spark is not an accurate measure of electromotive force. As regards Mr. Mordey's observation, he thought the action explicable on the theory of the leading condenser current acting on the field magnets. The same explanation is also applicable to the Deptford case, for when the dynamo is direct on, the condenser current is about 10 amperes, and this exerts only a small influence on the strongly-magnetised magnets. When transformers are used, the field magnets are weak, whilst the condenser current rises 40 amperes.

Mr. BLAKESLEY's method of determining losses was, he said, inapplicable except where the currents were sine functions of the time, and consequently could not be used to determine loss due to hysteresis in iron, or in a transparent dielectric.

Mr. SWINBURNE's "Note on Electrolysis" was postponed till next meeting.

### NEW PATENTS—1890.

19033. "Improvements applicable to switches used for electrical purposes." WOODHOUSE and RAWSON, Limited. (Communicated by A. W. T. Hinde, Australia.) Dated November 24.

19034. "Improvements in automatical electrical apparatus." R. J. JONES and WOODHOUSE and RAWSON, United, Limited. Dated November 24.

19035. "Improvements in dynamos for firing explosive charges or for medical purposes." F. W. DODD. Dated November 24.

19037. "Means of neutralising or controlling the polarity of iron or steel for the protection of magnetic needles from local attraction." J. S. GISBORNE. Dated November 24.

19049. "Improvements in electric lighting appliances for photographic and other purposes." F. L. MUIRHEAD. Dated November 24.

19052. "Improved combination of ingredients constituting a compound as an illuminating medium for electric incandescent lamps." M. N. MALLISON. Dated November 24.

19057. "Improvements in electric arc lamps." W. P. THOMPSON. (Communicated by R. H. Beach, United States.) Dated November 24. (Complete.)

19076. "Improvements in electric safety fuses." W. M. MORDEY. Dated November 24.

19079. "Electric cables." J. ARMSTRONG. Dated November 25.

19083. "An automatic electrical latitudinal indicator and ships' course registering compass." J. O'NIEL. Dated November 25. (Complete.)

19097. "Improvements in and in the method of manufacturing incandescent electric lamps and other exhausted receivers." A. M. CLARK. (Communicated by A. Bernholdt and J. Glatz, United States.) Dated November 25. (Complete.)

19108. "Improvements in or connected with combinations of hydraulic, pneumatic, and electric means for obtaining, transmitting, and applying motive power." C. ADAMS-RANDALL. Dated November 25.

19155. "Improvements in electrical storage batteries or accumulators." H. H. LAKE. (Communicated by G. E. Hatch, United States.) Dated November 25. (Complete.)

19162. "Improvements in methods of electric welding and metal working." M. W. DEWEY. Dated November 25. (Complete.)

19191. "Improvements in and relating to underground electric tramways." M. WHELESS and S. E. WHEATLEY. Dated November 25. (Complete.)

19203. "Improvements in the manufacture of thin metal tubes by electrolysis." L. HAUSMANN. Dated November 25.

19234. "A method of and apparatus for controlling gas lighting in cases of failure of electric light installations." H. C. SWINDELL. Dated November 26.

19239. "Improvements in electric switches." H. BARTON. Dated November 26.

19272. "Electric soldering irons." C. E. CARPENTER. (Date applied for under Patents Act, 1883, Sec. 103. May 10th, 1890, being date of application in United States.) Dated November 26. (Complete.)

19308. "Improvements in and connected with electrical distribution of power by alternating currents, and their measurement." J. SWINBURNE. Dated November 27.

19315. "Improvements in electric arc lamps." H. NUNNS. Dated November 27.

19344. "Improvements in electrolysis in general, and particularly in electrolysis of metals." E. PLACET and J. BONNET. Dated November 27.

19345. "Improvements in suspension devices for incandescent lamps." A. J. BOULT. (Communicated by H. Rentzsch, Germany.) Dated November 27.

19355. "An improved electrical connection or plug." S. BACON. Dated November 27.

19406. "Improvements in electric current meters." E. HARTMANN and W. BRAUN. Dated November 28. (Complete.)

19418. "Improvements in electrical tell-tales for twin-screw steamers." G. HANNAH. Dated November 28.

19423. "Improvements in apparatus for the electrolytic production of gases." E. A. DUCRETET. Dated November 28.

19467. "Improved electric arc lamp." J. P. BAYLY. (Communicated by A. Wagnière, U.S.A.) Dated November 29.

19485. "Automatic railway signalling by electricity." H. E. G. EARLE. Dated November 29.

19496. "Improvements in insulators." J. F. MUNSIE. Dated November 29. (Complete.)

19504. "Improvements in systems of electrical distribution." W. S. RICHARDS and G. B. JAMES. Dated November 29.

19505. "Improvements in the method of, and in the machinery for, the manufacture of lead or metallic boxes and plates for electric accumulators, and other kinds of lead or metallic boxes, plates, tubes, rods and strips of irregular section, or plain, ribbed, corrugated and fluted by hydraulic pressure." A. WYLIE. Dated November 29.

19552. "Improvements in telephonic apparatus, the improved magnets of which may be used in other electrical apparatus or machinery." R. H. COURTENAY. Dated December 1.

19555. "A portable room for telephone." F. A. OETZMANN. Dated December 1.

19601. "Connecting and regulating telegraph, telephone, or electric lighting wires." W. GRIFFITHS. Dated December 2.

19650. "Improvements in the distribution of electricity through accumulator batteries." SIEMENS BROTHERS & CO., LIMITED. (Communicated by Siemens and Halske, Germany.) Dated December 2.

19665. "Improvements in and relating to electro-magnetic traction increasing apparatus for railways." M. W. DEWEY. Dated December 2. (Complete.)

19724. "Improvements in carriers, supports, or galleries, for the shades or globes of electric lights or gas lamps." V. SILBERBERG. Dated December 3.

19740. "Improvements in column printing telegraph receivers." F. H. W. HIGGINS. Dated December 3.

19744. "Improvements in and relating to electric belts and similar appliances." C. B. HARNESS. Dated December 3. (Complete.)

19762. "Improvements in and connected with electrically indicating pressure gauges." W. C. MORISON. Dated December 4.

19806. "Improvements in circuit controllers or switches for incandescent electric lamps." N. MARSHALL. Dated December 4. (Complete.)

19811. "Improvements in apparatus for use in propelling vehicles by electricity." F. WYNNE. Dated December 4.

19813. "Improvements in the production and distribution of alternate electric currents." A. GAY, W. F. TAYLOR and R. HAMMOND. Dated December 4.

19834. "Improvements in controlling levers of railway signal interlocking apparatus for the application of electricity." W. F. BURLEIGH. Dated December 5.

19840. "Transforming paper or other wrapping material into sufficient strength or pertinacity to use as an insulator in all electrical matters and cables." W. EDWARDS and W. SANDBACH. Dated December 5.

19842. "Improvements in roses for ceilings and wall connectors, for electrical purposes." W. H. STURGE and J. GRUEB. Dated December 5.

19883. "Improvements in or relating to self-controlling electrical signals for the prevention of railway accidents." L. CAPOCCI, C. PICONE and A. SPACAGNA. Dated December 5.

19942. "Improvements in galvanic batteries, and in the electro-chemical formation of chlorine and chlorine compounds applicable for such batteries and other purposes." W. P. THOMPSON. (Communicated by F. Marse, Germany.) Dated December 5. (Complete.)

### ABSTRACTS

#### OF PUBLISHED SPECIFICATIONS 1889.

16237. "Improvements in electrical mains and in their manufacture." S. Z. DE FERRANTI. Dated October 15. 8d. In order to insulate the several lengths of the rods or tubes, the inventor winds around each length a sheet or sheets of paper soaked in an insulating material, say, for example, melted paraffin, and this he does by rotating the rod or tube and causing it to wind the paper around itself. He uses sheets of paper each of a length equal to the length of the rod or tube to be covered and of any convenient width so that when wound on to the rod or tube the several layers of paper may be complete in themselves and uniform insulation be obtained throughout the length of the rod or tube. 12 claims.

17142. "Improvements in electro-magnetic induction apparatus for transformers, generators, or motors." L. BOLLMANN. Dated October 29. 8d. Relates to certain parts termed magnetic locks, which might be either of two kinds. A lock of the one kind is a movable piece of iron which in one position forms part of a magnet and in another position makes a break of the magnet so that as the magnetic circuit is thus closed or opened, electric currents are induced in coils surrounding the magnet or parts of it. A lock of the other kind is also a piece of iron forming part of a magnet but of smaller diameter than the body of the magnet itself, and surrounded by a coil through which electric currents can be transmitted in either direction. When they pass in the one direction the magnetic circuit is virtually closed; when they pass in the other direction, that circuit is virtually opened. Thus by alternations of current in the coil of the lock, which remains itself stationary, inductions are caused as in the case where a movable lock of the former kind is employed.

18193. "Improvements relating to the manufacture of insulators and other glass articles and to apparatus for use in such manufacture." DAN RYLANDS. Dated November 14. 11d. Has for its object the manufacture or moulding, more rapidly than hitherto and by labour-saving apparatus, of glass articles and especially of such articles as require a large body of glass in proportion to their size, as, for instance, insulators, insulating jockeys, and other articles in glass were made principally if not altogether by casting, moulding or pressing the glass in suitably-shaped moulds. 4 claims.

18350. "Improvements in dynamo-electric machines." J. H. DAVIES. Dated November 16. 8d. Consists in placing two separate circles of commutator segments on the spindle of the machine arranged and connected as if from an ordinary commutator every alternate segment was removed and displaced longitudinally on the spindle until it was beyond the original commutator, the gaps between the segments in both circles being preferably filled with insulating material such as mica or glass. 2 claims.

18755. "Improvements in the manufacture of plates for use in secondary batteries or electrical accumulators." A. RECKENZAUN. Dated November 22. 6d. The inventor places a plate of lead or other suitable metal in contact with one pole of a dynamo or other generator of electricity, and causes the plate to travel under a conducting point, or allow the conducting point to pass over the surface of the said plate. 2 claims.

18841. "Improvements in apparatus for laying and picking up submarine cables." G. DRAPER and P. L. ISAAC. Dated November 23. 1s. 1d. In place of bolting to the deck a number of girders with spaces between, the inventors employ a single steel casting which may taper from the bow to aft, and to the front of this casting they bolt a number of plates or steel castings technically known as "whiskers" projecting over the water and separating and supporting the sheaves in a similar manner to the girders. At each side of the apparatus they place a horizontal grating supported by the two outside whiskers. 5 claims.

19011. "Improvements in dynamo-electric machines." J. HOPKINSON. Dated November 26. 8d. It is usual to construct the cores of the armatures of dynamo machines of plates of iron insulated from each other. These plates are in the form of rings and when of large size are expensive. The inventor attains the same effect as is obtained by entire rings both magnetically and mechanically by employing segments of rings arranged in layers the joints between the segments breaking joint between successive layers. The friction between the plates is sufficient to keep them in place just as well as if they were entire rings. When a high tension is required he winds the conductor on the following principle, for example, suppose there be 12 poles he winds a number of sections on the armature then advances one-sixth part of the circumference and winds a like number then advances another sixth part and wind on, and so on, until the whole is wound. 2 claims.

19190. "Improvements in and relating to induction coils and electro-magnets." E. L. LOVELL and A. F. LLOYD. Dated November 29. 6d. Upon a centre formed either of a solid soft iron pin or of a bundle of soft iron wires, the inventors wind one or more layers of insulated wire preferably also of soft iron. Upon this coil of wire is disposed a split tube of soft iron, or preferably a plate of ferrotype iron, bent into a cylindrical form, which, serving as an electro-magnetic condenser, would be secured by a cap attached to each end of the soft iron pin above mentioned or by equivalent means. 2 claims.

19199. "Improved means for the prevention of polarisation in electric batteries." H. BADCOCK, H. GRUNSELL and A. WALKER. Dated November 29. 6d. Polarisation in electric batteries is prevented by imparting a continuous or periodical motion or disturbance to the liquid, the invention being primarily intended to be used with bichromate of potash batteries. 1 claim.

19525. "Improvements in electricity meters." W. H. SCOTT and L. PARIS & SCOTT, LIMITED. Dated December 5. 8d. Consists of modifications and improvements to the apparatus described in Letters Patent dated 1888, No. 16,623. 7 claims.

19554. "Improvements in the connections of alternating current generators and electric motors." M. VON DOLIVO-DOBROWOLSKY and "ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT." Dated December 5. 11d. The different coils, instead of being independent, are conductively connected together in each machine,

and the connections between the respective coils of the two machines are such that the coils of the generator supply electric impulses to two or more of the connecting wires or mains simultaneously, though these impulses vary in degree relatively to each of them, and that each impulse transmitted through a main is distributed upon two or more coils of the motor. 2 claims.

19555. "Improvements in electrical induction apparatus or transformers." M. VON DOLIVO-DOBROWOLSKY and the Company "ALLGEMEINE ELEKTRICITÄTS GESELLSCHAFT." Dated December 5. 8d. Claim:—An induction apparatus consisting in a number of cores of iron forming together three or more closed or nearly-closed magnetic systems, primary and secondary coils placed on said cores, electric circuits connected to the primary coils, and means for creating in the said circuits alternating currents of successive phases, for the purpose of causing a continuously-progressive shifting of the magnetic axis and maintaining nearly constant the total amount of magnetism, substantially as described.

19831. "Quick make and break electric switches." C. M. DORMAN and R. A. SMITH. Dated December 10. 8d. Claim:—In switches of the quick make and break class described and shown in the specification of Belna Egger, A.D. 1887, No. 5092, the method of attaching either directly to the handle moved by the operator or to mechanism suitably geared thereto one or more parts so arranged as to positively transmit the motion of the handle to the contact lever in either making or breaking contact and so render the switch effective if from any reason the force of the spring or springs is insufficient to overcome the friction of the switch, substantially as described and shown in the drawings.

19951. "Improvements in electrical switches." H. BAYLEY. Dated December 11. 8d. Has for its object the construction of electrical switches in such manner that the contact pieces (or contact makers and breakers) may make and break contact with the terminal plates or blocks simultaneously over the entire bearing area between such parts and be also capable of rubbing contact therewith. 5 claims.

20856. "Improvements in elements for voltaic batteries." D. G. FITZGERALD and A. H. HOUGH. Dated December 28. 6d. Relates to the use of the "lithanode" mixtures and consists in coating the leaden support electrolytically with a layer of peroxide of lead before applying any of the mixtures. 4 claims.

## 1890.

7383. "An improved battery element." J. N. LEVSEN. Dated May 12. 6d. Claim:—A new battery element, consisting of the carbon and zinc electrodes, a mixture of pulverised retort carbon and manganese, covered with a mixture of resin and pitch, all approximately in the proportions set forth, and a sack of sail cloth or other like material encompassing the whole, substantially as and for the purposes described and illustrated in the drawings.

7465. "Improvements in apparatus for telephone exchanges." J. E. KINGSBURY. (A communication from abroad by the Western Electric Company, of Chicago). Dated May 13. 8d. Relates to multiple switchboard systems of telephone exchange, and its objects are, first, to reduce the amount of wiring required between the different boards; and, second, to reduce the size of the switches, so that a larger number of lines may be brought within the reach of each operator. 12 claims.

## CORRESPONDENCE.

### Improvements in Telephone Switchboards.

I have seen the correspondence going on relative to the above subject, and as I am much interested in this important matter of switching, I should feel obliged if Mr. Kingsbury would answer the following questions, viz.:—

1. Seeing that  $14\frac{1}{2}$  feet is occupied by 1,000 subscribers, what is the greatest stretch, in feet, of the cord, presuming that the 10 boards are in one line?
2. In the event of 2,000 subscribers to the exchange at which these boards exist, in what manner would the boards be arranged?
3. What number of operators are employed to work the 10 boards, and would the number be double for 20 boards?
4. When would the exchange attain multiple rank, and in what manner would the boards and connections be arranged for such?
5. Where is the exchange at which these ten 100-line boards exist?
6. Why not give an outline of the connections, as was done in the single-cord system, and thus allow one more able to judge its merits?

Mr. Kingsbury is evidently much in favour of his own system, and dislikes that patented by Messrs. Jackson and Sinclair; but having been shown the single-cord system by the latter gentleman, I must say *I admired the perfectness of its working*. I observe that Mr. Kingsbury has obtained protection for certain details in his system, but I fail to see, by his article of 31st October, anything very special in it, and therefore I may trouble you, ere long, with the illustration of an unpatented arrangement, proposed by myself, with a view of arriving at, or perfecting, a system worthy the brains of England's electricians.

An Electrician all his Life.

December 20th, 1890.

#### The Institution of Electrical Engineers.

Allow me to make two very necessary corrections in your report of the observations I made at the last meeting of the Institution of Electrical Engineers. The formulæ:

do not express "the chemical changes produced by electrolysis," but the composition of a certain sample of *lithanode*, which I was inclined to regard as a type of the active material in the negative element of a lead secondary battery. The former of the two expressions is the empirical, and the latter the theoretical formula. The second correction is that I have not yet obtained a discharge of 2 ampères per lb. gross weight of cell for two hours. This is what I am trying to get; but one and a-half ampères for the two hours is the most I have actually obtained.

Desmond G. FitzGerald.

[We are sorry that Mr. FitzGerald should be compelled to write to us; the report is not ours, but the authorised abstract of the discussion sent out under the auspices of the Institution. There was a time when such corrections would not have been necessary.—EDS. ELEC. REV.]

#### Underground Cables.

In your issue of the 19th inst. you publish two letters, one from Mr. Mavor and the other from Mr. Ferranti, having reference to a letter from our Liverpool agent published in the ELECTRICAL REVIEW of the 5th inst.

With regard to the cables in use at West Brompton, the statement made in the paper on Central Station Lighting was that the Fowler-Waring cables were not exclusively used by the House-to-House Company, but have been found to be the most satisfactory up to the present time. From Mr. Mavor's letter it would appear that we are incorrect in saying that these cables have been abandoned at West Brompton, and that their use has only been postponed. If this is so, still they can hardly be considered as "the most satisfactory up to the present," as our vulcanised cables are, we understand, in daily use; and Mr. Mavor admits that the difficulty to be overcome before the Fowler-Waring cables can be used is a serious one. This difficulty presumably existed at the time the paper referred to was read in January, and it appears has not yet been overcome, and the cables have not yet been in ordinary service.

With regard to the London-Deptford cables, the original statement made was, that "certainly these have been the only cables which have withstood the voltage employed by the London Electric Supply Corporation for any time; and though they subsequently developed faults, the tension (*i.e.*, 10,000 volts) was phenomenal," &c.

From Mr. Ferranti's letter it would appear that these cables are only working at 2,500 volts, and are not sufficiently insulated for the higher voltage. This does not bear out the original statement made—that these are the only cables which have withstood 10,000 volts; and although the expression, "we believe these cables have been condemned," may appear strong, in your issue of the 4th April last you refer to the "breaking

down of the Fowler-Waring cables," and in the report of the meeting of the London Electric Supply Corporation contained, in the same issue, the following occurs as an extract from the engineer's report:—"The defective mains now in use between Deptford and London will shortly be replaced by these permanent trunk mains" (*i.e.*, mains manufactured by Mr. Ferranti); and, further, in your issue of the 25th of the same month, you state "That the cables, so far, have proved to be unreliable is well known."

Surely if such statements go uncontradicted, it is a fair assumption that these cables are not reliable, and that they are to be replaced—in other words, that they are condemned.

We wish to point out that, no doubt from an oversight, several words of our agent's quotation from Mr. Ferranti were omitted from his letter, as printed in your issue of the 5th inst., and that by this omission the sense of the paragraph is entirely altered.

Wm. J. Tyler,

Secretary of the I.-R. G.-P., and T.W. Co., Ltd.

22nd December, 1890.

#### British Insulated Wire Company's Cable.

Owing to absence from Liverpool, I have just had the pleasure of reading your issue of the 12th to-day, and I notice therein a leaderette criticising the data of some tests of the above-mentioned company's manufactures.

You apply certain terms to my letter containing the figures observed, which, representing as they do your opinion, cannot be cavilled at, but how far they are merited by the MSS. you so roughly handle is questionable. The truth only having been recorded in the report referred to, it is open to anyone to cavil at the mere style of the writer, which may afford sport to any Philistine.

You state that you find "it difficult to judge of the value of the tests from insufficiency of information."

The tests were taken solely to ascertain the dielectric resistance under various conditions, electrification and capacity of electric light and telephone cables, sample lengths suitable for the purpose being used. As the tests were completed satisfactorily, mechanical data of the cables were not included. As I am aware that all your comments are intended for the public good, there is no better reply to make to your statements than to ask you to again look into the figures and impartially to weigh the results obtained which have here and elsewhere been considered most favourable. It is questionable if the substance of the letter could have been given in a few lines, as the matter included only contained such information as would be required by anyone attempting to repeat these tests. The cables were all lead-covered, but the reference made to the telephone cable maintaining its insulation in the rain had regard to the fact that the lead had been stripped off for about 12 inches at each end, and it was in this condition that the sample was left exposed, and tested after merely surface drying.

The two-yard length of electric light cable had been twisted and bent after the lead sheathing had been removed, and before immersion. In comparison with certain other cables of similar type of insulation, the test was very severe, and is conclusive evidence that the material used does not absorb moisture.

It is, of course, of the greatest interest to the electrical world to ascertain the accuracy and magnitude of tests made on cable samples, and in this light your leaderette has, I trust, elicited the information desired.

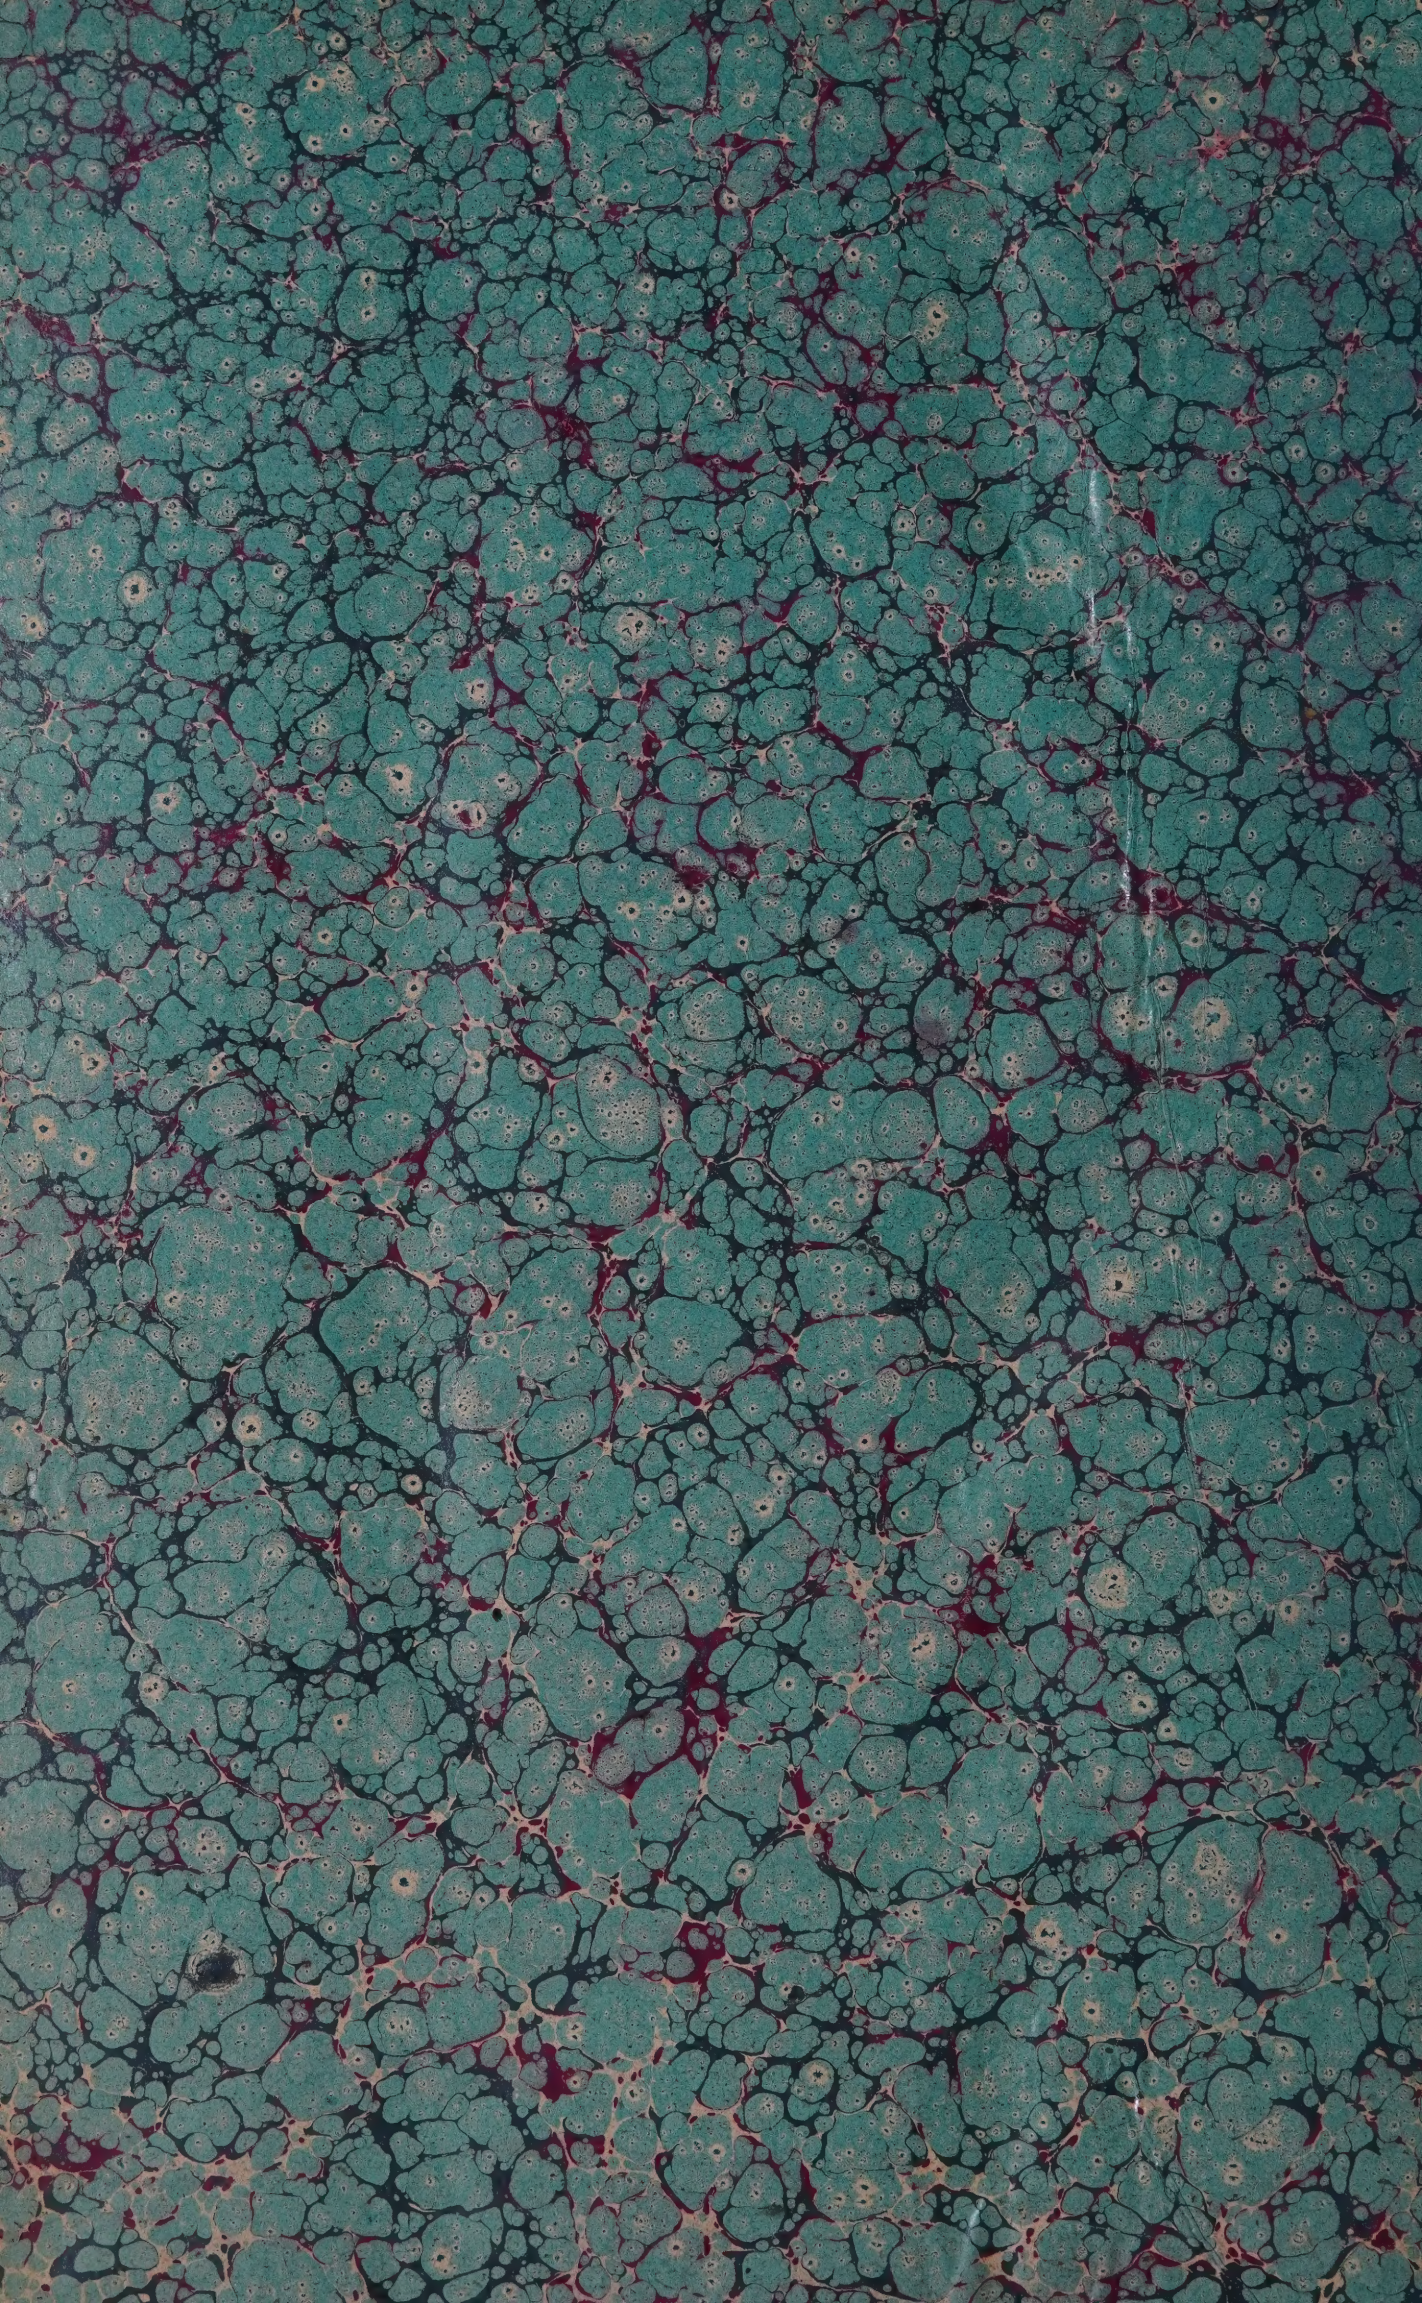

Charles H. Yeaman.

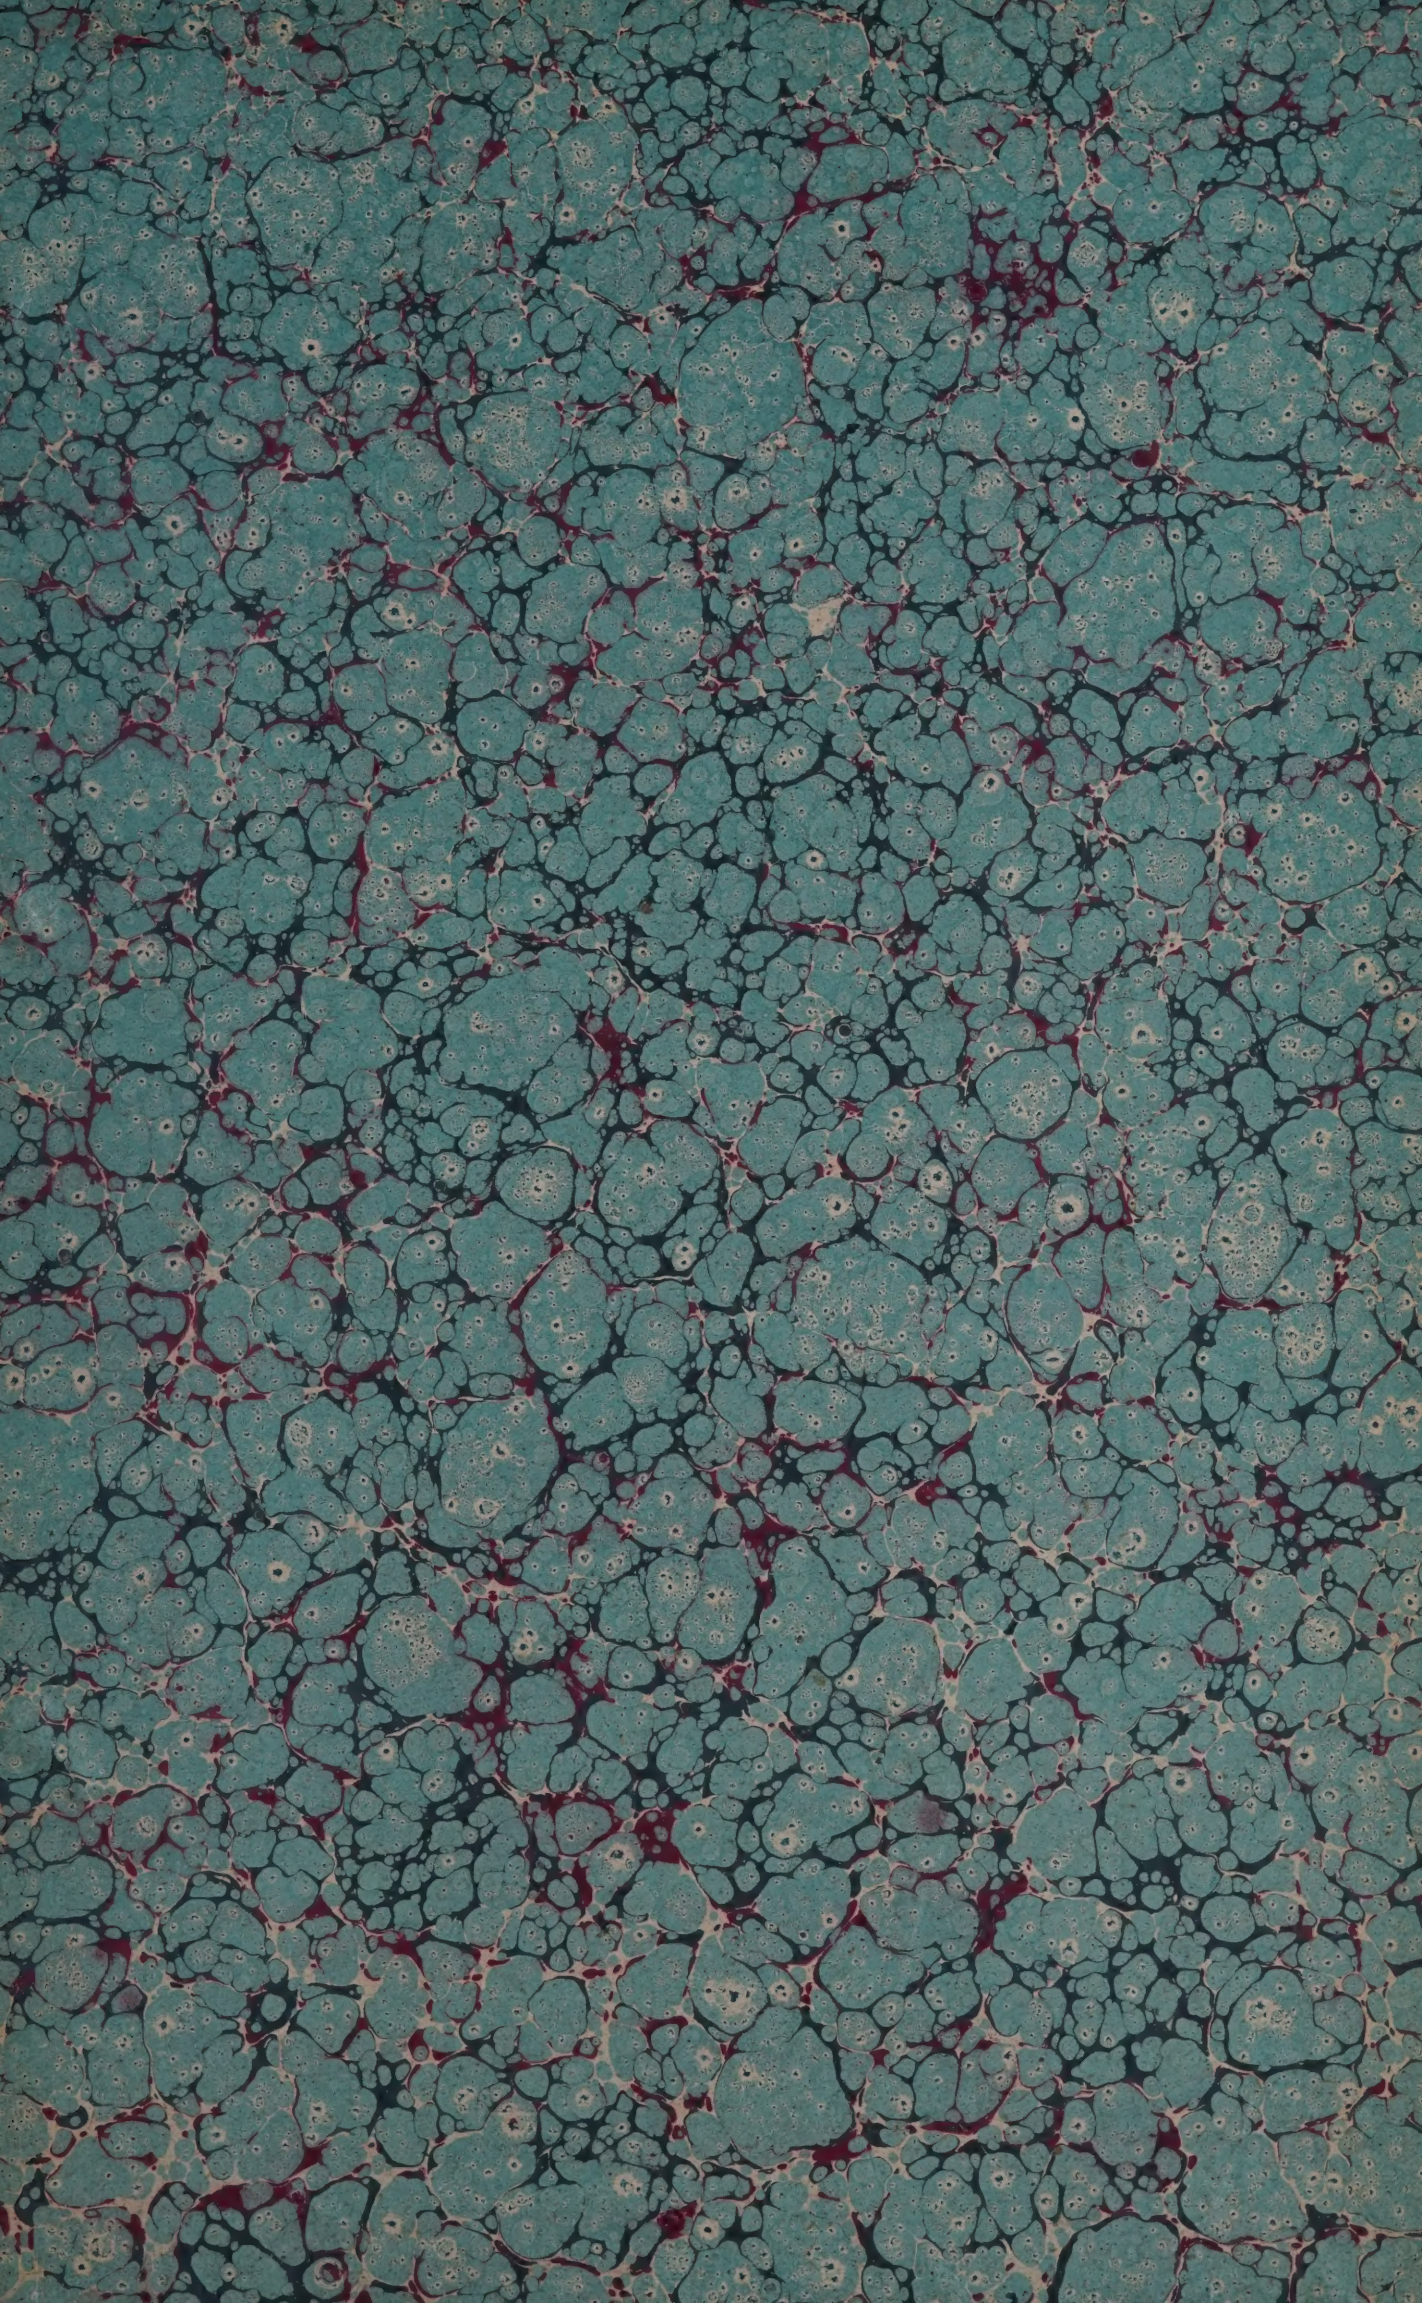

2, Albany Place, Glasgow, W.

December 20th, 1890.

[Mr. Yeaman has now given the information, of the lack of which we complained. The results of the tests (which we consider were properly made) under the conditions stated, certainly show the insulation of the cables in a very favourable light.—EDS. ELEC. REV.]
